The astronomers say, the moon, or any planet, is *falcated*, when the enlightened part appears in form of a sickle, or reaping-hook, by the Latins called *falx*.

The moon is *falcated* whilst she moves from the third quarter to the conjunction, and from the conjunction, to from new moon, to the first quarter; from hence to opposition or full, and from full to the third quarter the enlightened part appears gibbous, and the dark *falcated*. See MOON.

FALCATOR, in our *Old Writers*, the servile tenant who performed service of falcature.

FALCATURE, *Falcatura*, in our *Old Writers*, signifies one day's mowing of grass, a customary service to the lord by his inferior tenants. Kennet's Gloss. in voc.

FALCINELLUS, in *Ornithology*, the name of a bird in some sort resembling the herons, but with a shorter beak. It is of a very beautiful colour, but with a fine glossy green with an admixture of a purplish tinge; the head and neck are brown, but the upper part of the throat whitish with black spots; its beak is like that of the curlew, very long, very slender, and crooked; its legs moderately long; as this bird grows older, it becomes of a browner hue. It is called by some, *ardea nigra*, the *black heron*, and by the Italians *asion negro*. Ray's Ornithology, p. 218.

FALCON, *Falco*, in the Linnæan system of *Zoology*, makes a distinct genus of birds of the hawk-kind, the characters of which are, that they have a strong hooked bill, the base of which is covered with a *cere*, or naked skin; the head is covered with feathers, and the tongue is bifid. Linnæus classes no less than thirty-two species under this genus, among which are the eagle, the buzzard, the kestrel hawk, the lanner, the gothawk, &c.

Jo. de Janu, and several others, take the name *falcon* to have been occasioned by its crooked talons, or pounces which resemble a *falx*, or sickle. Giraldus derives it *a falcando*, because it flies in a curve.

The *falcon* is a bird of prey of the hawk-kind, much esteemed for its strength and activity. There are many species of this bird; but when the word *falco* is used singly, without any distinctive addition, it is meant of that species, called by authors the *falco peregrinus*, from its travelling into different countries, at different seasons of the year.

It has very long and large wings, reaching when folded to the tip of the tail. Its shoulders are very large, its tail very long, and ending like the sparrow-hawk's in a point, its end being white, variegated with orange coloured streaks. Its feet are of a greenish or bluish yellow, its neck is long, and its head and back of a pale dove colour. There is a variety of this bird, which is of a much blacker colour on the back, and has been erroneously esteemed by some a different species; probably it is only owing to the difference of age or sex. This bird is caught in France, Germany, and elsewhere; but it is not well known where it builds. It feeds on ducks, geese, and other large birds.

This species builds on the rocks of Llandilno, in Caernarvonshire, and is very common in the North of Scotland. Mr. Pennant mentions a surprising instance of the rapidity of their flight; one that was reclaimed by a gentleman of the shire of Angus, on the east side of Scotland, eloped from his master with two heavy bells to each foot, on the twenty-fourth of September, 17[illegible]2, and was killed in the morning of the twenty-sixth, near Moliyn in Flintshire. Zoology, vol. i. p. 170.

The *falcon* is of the long-winged hawk-kind, used in the diversion of hawking. There are several species of *falcons*. 1. The *falco peregrinus*, or common *falcon*. 2. The same, called *falco sacer* by authors. 3. The *jer-falcon* or *gir-falcon*. 4. The *mountain-falcon*. 5. The *gentle falcon* or *falco gentilis*, suspected by Mr. Ray to be the same with the common or first kind. 6. The *haggard-falcon*, remarkable for the shortness of its neck. 7. The *white falcon*, all over of a pure snow-white. 8. The *sleeve-falcon*, of a deep blackish blue. 9. The *Tunis* or *Barbary falcon*, which resembles the common kind, but is smaller. 10. The *red falcon*, much resembling the common kind, but spotted with a reddish colour; and the red and crested Indian *falcon*, which seem to be the male and female of the same species. Ray's Ornithol. p. 40 to 48. See GYRFALCON, SACRE, LANNARIUS, &c.

To these we may add the *spotted falcon*, about the size of a buzzard, with a black bill, yellow cere and legs, pale yellow irides; the crown and hind part of the neck white, spotted with light reddish brown; back and scapulars of the same colour, edged with white; the quill-feathers dusky, barred with ash colour; the underside of the neck, breast, belly, and thighs, white, and very strong legs, and also the *rough-legged falcon*, a native of Denmark, in length about two feet two inches, with a dusky bill, yellow cere; the head, neck, and breast, of a yellowish white, marked in some parts with oblong brown strokes; the belly of a deep brown; the thighs and legs of a pale yellow, marked with brown; the extreme half of the tail brown, tipt with dirty white; that next to the body white; the legs covered with feathers as low as the feet, and the feet yellow. Pennant's British Zoology, vol. i. p. 191; and vol. ii. p. 623.

It must be added, that the name *falcon* is restrained to the female; for as to the male, it is much smaller, weaker, and less courageous, than the female; and is denominated a *tassel* or *tercelet*.

The gentle *falcon*, with yellow legs, ash-coloured body spotted with brown, and four or five blackish bars on the tail, is the most valuable of all these, as being the most tame and manageable, and the most hardy, enduring all weathers without hurt. It makes its nest in rocks, and inhabits the North of Scotland. This kind of *falcon* has a natural inclination to make the heron fly every way, and to

moſt excellent as the brook or river fowling, and eſpecially at the larger birds, as at the ſhovel, wild goose, and the like. If the be an eyeſſe ſhe may be ventured at the ſtone, otherwiſe ſhe will not be ſo hardy.

Hawks in general prove courageous or cowardly all their lives, as they are firſt quarried; and if they are taken out of the eyrie before they are fully ſummed and well penned, their wings will never grow to perfection. Their legs, alſo, will grow crooked, and their train will be full of taints. *Falcons* of one and the ſame kind are called by the ſportſmen by very different names, and eſteemed of ſeveral different kinds according to the places and time of their reclaiming, and the countries from whence they came. Thus the names mewed-hawk, ramaged-hawk, ſoar-hawk, and eyeſſe, firſt commenced; and theſe are again divided into large hawks, wean hawks, and ſtender hawks. All theſe have different nails and plumes, according to the country from whence they come; ſome are black; ſome brown; they have alſo each its different diſpoſition, ſome being beſt for the field, and others for the brook or river. Different names are alſo given to *falcons*, according to their different age and time of taking. The *falcon* is called an eyeſſe as long as ſhe remains in the eyrie; theſe are always troubleſome in their feeding; they cry very much, and they are not entered without great difficulty; but being once well entered, they prove excellent hawks for the heron and all the large fowl, and are very hardy and full of courage. The ſecond name given this bird is the *ramage-falcon*. This name ſhe retains from the time of her leaving the eyrie, during the months of June, July, and Auguſt. Theſe are always hard to be manned; but being reclaimed, they are not inferior to any hawk. The third is the *ſoar-hawk*, ſo called in September, October, and November. Theſe birds keep for a whole twelvemonth the firſt feathers, which they have on when they leave the eyrie, and do not moult them. Theſe are therefore called the ſoar-feathers. The fourth is termed the *murramolt* or *caſt*, *quaſi* carry-fit; for they muſt at this time be almoſt continually carried on the fiſt. They are thus called from January to the middle of May. Theſe are uſually great baſtes, and very little eaters; they are ſubject to ſeveral troubleſome diſorders, particularly to the *filanders*, more than any other hawk, and they are very ſeldom brought to be good for any thing. The fifth name is the *entermew*. They are called by this name from May till December, becauſe all that time they are caſting their coats. Theſe would be excellent hawks if they could be truſted; but they are unſteady. They muſt be kept hard under, and the falconer muſt make his fiſt their perch. The hawk newly taken muſt be feeled, have all new furniture, and muſt be often ſtroked with a ſtick to accuſtom her to be gentle. She muſt alſo have two good bells, that ſhe may be well heard when ſhe ſtirs or ſcratches; and her beak and talons muſt be cut a little, but not ſo near as to make them bleed. If there be a *ſoar-falcon* taken that has already croſſed the ſeas, ſhe is uſually very hard to be broken; but that being well done, ſhe is the beſt of all hawks. Her food muſt be good and warm, and it muſt be given her at leaſt three times a day. It ſhould be pigeons, larks, or other live birds; for ſhe muſt be broke by degrees from her accuſtomed manner of feeding. The hawk muſt always be fed with hoop and lure, that ſhe may always know when you will give her meat. She muſt then be gently unhooded, and two or three bits being given her, ſhe muſt be hooded again; and in the night let her rooſt on a perch near ſome perſon's bed, that ſhe may be often waked in the night. When by theſe means ſhe becomes tame and gentle, her uſual food may be changed, and a ſheep's heart given her. After this ſhe may be unhooded in the day-time, but not in company; and after giving her a bit or two, ſhe muſt be hooded again, and then a little more given her. After this, by degrees, ſhe will be taught to eat before company, and then the buſineſs of taming her will be ſoon accompliſhed. Till ſhe is thoroughly manned, ſhe muſt be borne continually on the fiſt, and feal in company, giving her in the morning about ſun-riſe the wing of a pullet, and every evening the foot of a hare or rabbit cut off above the joint, ſtead and laid in water, which having ſqueezed give it her with the pinion of a hen's wing. It is beſt to give the hawk waſhed meat, and after this plumage, according as ſhe ſeems to be foul within. She is then to be hooded, and nothing more ſhould be given her till ſhe gleams after caſting, but when ſhe has gleamed and caſt, ſhe ſhould then have ſome hot meat given her, toward evening eſpecially, and be made to eat it in company. When ſhe is well reclaimed, manned, and ſharp-ſet, ſhe may be fed on the lure.

But three things are to be conſidered before your lure be ſhewed her. 1. That ſhe be bold and familiar in company, and not afraid of dogs and horſes. 2. Sharp-ſet and hungry, having regard to the hour of morning and evening when you would lure her. 3. Clean within, and the lure well garniſhed with meat on both ſides. When you intend to give her the length of a leath, you muſt addreſs yourſelf; ſhe muſt alſo be unhooded, and have a bit or two given her on the lure, as ſhe ſits on your fiſt. That done, take the lure from her, and ſo hide it that ſhe may not ſee it; when ſhe is unſeeled, caſt the lure to near her, that ſhe may catch it within the length of her leath; and as ſoon as ſhe has ſeized it, uſe your voice as falconers do, feeding her upon the lure on the ground.

After having lured your *falcon*, in the evening give her but little meat, and let this luring be ſo timely, that you may give her plumage, *&c.* next morning on your fiſt; when ſhe has caſt and gleamed, give her a little breaching of warm meat about noon, tie a creance to her leath, go into the field, there give her a bit or two upon the lure, and unſeal her. If you find ſhe is ſharp-ſet, and has eagerly ſeized on the lure, let a man hold her, to keep her off to the lure; then unwind the creance, and draw it after you a good way, and let him who has the bird hold his right hand on the taſſel of her hood ready to unhood her as ſoon as you begin to lure; to which if ſhe come well, ſtoop roundly upon it, and haſtily ſeize it; let her caſt two or three bits thereon; that done, take her off the lure, and deliver her again to the perſon that held her; and, going farther off the lure, feed her as before; and ſo daily farther and farther off the lure. Afterwards you may lure her in company, but do not feed her; and having uſed her to lure on the foot, do it alſo on horſeback; which may be ſooner accompliſhed, by cauſing horſemen to be about you, when you lure her on foot; it is alſo ſooner done, by rewarding her upon the lure on horſeback among horſemen. And when ſhe is grown familiar this way, let ſuddenly a-foot hold her, and he that is on horſeback muſt caſt the lure about his head, while the other takes off the hood by the taſſel; and if ſhe ſtoop roundly at the lure, without fear of a man or horſe, then take off the creance, and lure at a greater diſtance. Laſtly, if you would have her love dogs as well as the lure, call dogs when you give her plumage. See HAWKING.

FALCON, in *Gunnery*. See FALCONET.

FALCONE, in *Zoology*, a name by which ſome authors have called the *miluus*, or FLYING-*fiſh*.

FALCONER, a perſon who brings up, tames, and makes, that is tutors and manages birds of prey; as falcons, hawks, *&c.* The grand ſeignor uſually keeps ſix thouſand *falconers* in his ſervice. The French king has a grand *falconer*, which is an office diſmembered from that of great hunt, grand veneur. The duke of St. Alban's is hereditary grand *falconer* of England.

Hiſtorians take notice of this poſt as early as the year 1150. One great buſineſs of the *falconer* is to conſider the quality and mettle of the birds, to know which to fly early, and which late. He muſt alſo be buſy and cleanly in freeing them of lice, nits, and vermin. Every night after flying, he ſhould give his bird caſting; nor muſt he forget to water her, unleſs ſhe have been bathed. After this, ſhe muſt be put in a warm room, having a perch, with a candle burning by her, where ſhe is to ſit unhooded, that ſhe may prune and pick herſelf. Next morning ſhe ſhould be weathered, *&c.*

FALCONET, in *Gunnery*. See FAUCONET.

FALCONRY, or FAUCONRY, the art of taming, managing, and tutoring, birds of prey, particularly falcons and hawks; and employing them with advantage in the purſuit of game; called alſo hawking. See FALCON.

The word is formed of *falco*, *falcon*, or *faucon*, the bird of moſt uſe and eſteem in this kind of ſport.

Falconry, though the principal amuſement of our anceſtors, was unknown among the Greeks and Romans. All their writings do not furniſh ſo much as a proper name to call it by; ſo far are they from teaching us the terms. It is the French language alone, that has particular words for all the parts of *falconry* and hunting; and from them moſt of our terms, as well as what we know of the art itſelf, are borrowed.

This diverſion was in ſuch repute ſo late as the reign of James I. that ſir Thomas Monſon is ſaid to have given a thouſand pounds for a caſt of hawks; and the laws were very rigorous that tended to preſerve this pleaſure. In the 34th of Edw. III. it was made felony to ſteal a hawk; and to take its eggs, even in a perſon's own ground, was puniſhable with impriſonment for a year and a day, beſides a fine at the king's pleaſure; and in the reign of queen Elizabeth, the impriſonment was reduced to three months; but the offender was to find ſecurity for his good behaviour for ſeven years, or to remain in priſon till he did. According to Oleatius, the

diverſion

diverſion of *falconry*, is more followed by the Tartars and Perſians than it ever was in any part of Europe. Tom. i. p. 217. 328. See Pennant's Britiſh Zoology, vol. i. p. 171, &c.

The writers of reputation on *falconry*, are Deſparon, Franchiere, Tardiffe, Arreloucher, Dalagona, Latham, &c. M. de St. Martha has put the principles of the art into fine Latin verſes, in his Hierocoſophism, five De Re Accipitraria, libri tres.

There is alſo a treatiſe on hunting, hawking, and heraldry, printed at St. Alban's by Caxton, and attributed to dame Juliana Barnes.

FALD-*fee*, or FALD-*fey*, was anciently uſed for a rent or fee paid by ſome cuſtomary tenants, for liberty to fold their ſheep upon their own land.

FALDAGE, an ancient privilege, which ſeveral lords reſerved to themſelves of ſetting up ſheep-folds, or pens, in any fields within their manors, the better to manure them; and this not only with their own, but with their tenants ſheep.

This was alſo termed *ſecta faldæ*; and in ſome old charters *fald-ſoca*; in ſome place a fold *courſe*, or free-fold.

FALDELLA, a word uſed by ſome of the writers in ſurgery for a ſort of compreſs made of lift contorted together in ſeveral doubles.

FALDUSTOR was anciently uſed to ſignify the higheſt ſeat of a biſhop, incloſed round with a lattice.

FALDWORTH, among our *Old Writers*, was uſed to ſignify a perſon of age, ſufficient to be reckoned of ſome decennary.

FALL, *Deſcent*, in *Phyſics*, the tendency of any heavy body towards the centre of the earth.

Galileo firſt diſcovered the ratio of the acceleration of *falling* bodies; viz. that dividing the whole time of *falling* into equal parts, the body will *fall* thrice as far in the ſecond moment, as in the firſt; five times as far in the third; ſeven times in the fourth, &c. and ſo on in the order of the natural numbers. See ACCELERATION.

FALL *of waters, for ſtrength of ſite.* See GRAVITY.

FALLING *bodies, for the laws of.* See DESCENT.

FALL, *water.* See CATARACT.

FALL is alſo uſed in a moral ſenſe; as, the *fall* of Adam. See *Original* SIN; the *fall* of the Roman empire, &c. Authors contend, that Plato had a notion of Adam's *fall*, which he had learnt from Moſes. Euſeb. De Præparat. Evangel. lib. xii. cap. 12. quotes a fable from Plato's Sympoſ. wherein he thinks he finds the whole hiſtory allegorically related.

FALL, in *Muſic* and *Poetry*. See CADENCE.

FALL, a meaſure of length uſed in Scotland, containing ſix of the ells of that country, each of which is equal to 37$\frac{4}{10}$ Engliſh inches. See MEASURE.

FALL, among *Seamen*, denotes that part of the rope of a TACKLE which is haled upon. They ſay alſo that a ſhip hath *falls* when ſhe is not *ſtaſh*, but hath riſings of ſome parts of her decks more than others. Alſo a ſhip is ſaid to *fall off*, when being under ſail ſhe keeps not to near the wind as ſhe ſhould do.

FALL *not off*, at ſea, a word of command from him that conds the ſhip, ſignifying as much as keep the ſhip near the wind.

To FALL *aboard of*, is to ſtrike or encounter another ſhip, when one or both are in motion; or to be driven upon a ſhip by the force of the wind or current.

To FALL *a-ſtern*, is to be driven backwards, or to retreat with the ſtern foremoſt; and is expreſſed of the motion of a ſhip either under ſail, or at anchor.

To FALL *calm*, expreſſes a total ceſſation of the wind.

To FALL *down*, is to ſail or be conducted from any part of a river, towards ſome other part nearer its mouth or opening.

Cat-FALL. See CAT-*heads*.

FALLACY, FALLACIA, a deception, or falſe appearance, or report.

The Epicureans deny, that there is any ſuch thing as a *fallacy* of the ſenſes. According to them all our ſenſations, and all our perceptions, both of ſenſe and phantaſy, are true; they add, that ſenſe itſelf is the firſt grand criterion of truth. That the ſenſes are never deceived, they argue from their being incapable of all ratiocination and remembrance: hence they can neither add, take away, couple, nor diſjoin, they cannot, therefore, infer, conclude, or invent; and conſequently they cannot deceive by any inference or invention. This the mind may do, but not the ſenſe, whoſe buſineſs is only to apprehend what is preſent, e. gr. colours; not to diſcern or diſtinguiſh between this body and that. But a thing that barely apprehends, without pronouncing any thing, cannot deceive: add, that there is nothing to convict our ſenſes of falſhood. The right eye, e. gr. cannot convict the left, nor Plato's eyes, thoſe of Socrates; ſince the reaſons or pretenſions of each are equal; and the purblind perſon ſees what he ſees as much as the lynceus. Nor can a ſenſe of one kind convict another; as the ſight, the ſmell; becauſe their objects are different, and conſequently their reports or judgments are not of the ſame things. Thus, again, if I ſee a ſtick ſtraight when out of the water, but when in it crooked, my perception is altogether as true in the latter, as in the former caſe; i. e. it is true that I have the preceptlon or idea of the crooked ſtick, as of the ſtraight one; and this idea is all that the ſenſe ſuggeſts, ſo that it does not deceive. Laſtly, reaſon cannot ſhew our ſenſes miſtaken, ſince all reaſoning depends on previous ſenſations, and the ſenſes muſt firſt be true, before any reaſoning, founded thereon, can be ſo. Thus the Epicureans, whoſe ſyſtem is ſtrongly confirmed by what we have already laid down from Dr. Berkeley, concerning EXISTENCE.

The Carteſians, on the other hand, are continually exclaiming againſt the ſenſes, as the great ſources of all deception. Every thing with which our external ſenſes preſent us, they ſay, ſhould be ſuſpected as falſe, or, at beſt, dubious, till our reaſon has confirmed the report. They add, that our ſenſes, as being fallacious, were never given us by nature for the diſcovery of the truth, but only to point out what things are convenient and hurtful to our bodies.

The Peripatetics keep a middle courſe: they hold, that if a ſenſible object be taken in its common or generical view, the ſenſe cannot be deceived about it; for the ſight can ſee nothing but what is viſible, nor can it err in perceiving what is viſible, *quatenus* ſuch. But they add that if the object be taken under its ſpecific view, the ſenſe may be miſtaken about it; viz. from a want of the diſpoſitions neceſſary to a juſt ſenſation; as a diſorder in the eye, or ſomething uncommon in the medium, &c.

FALLACY, in *Logic*, or *ſyllogiſtic fallacy*, is a captious argument, called alſo a SOPHISM.

Fallacies either ariſe from words, or things: the foundation of an illuſion and *fallacy* in words, is ambiguity, which is of two kinds; viz. ſimple homonymia, and amphibology.

The kinds of *fallacy* in things are very numerous; but they may be reduced to ſeveral general heads, *viz. ignoratio elenchi, petitio principii, falſa cauſa, interrogatio multiplex, limitatio vitioſa, accidens, & conſequens.*

FALLING-*off*, in *Sea-language*, denotes the movement or direction of the ſhip's head to leeward of the point whither it was lately directed, particularly when ſhe ſails near the wind, or lies by. See FALL *not off*.

FALLING-*off* is alſo the angle contained between her neareſt approach towards the ſource of the wind, and her fartheſt declination from it when TRYING.

FALLING *evil* is a diſeaſe to which horſes are ſubject, proceeding from ill blood and cold thin phlegm collected in the fore-part of the head, between the panicle and the brain; which being diſperſed over the whole brain, cauſes the horſe ſuddenly to fall, and bereaves him for a time of all ſenſe. Spaniſh, Italian, and French horſes, are more ſubject to this diſeaſe than the Engliſh.

For the cure of this diſorder, bleed the horſe in the neck, and again in the temple veins and eye-veins, four or five days after; anoint his body all over with a comfortable friction, and bathe his head and ears with oil of bay, liquid pitch, and tar mixed together, and keep his head warm, by covering it with a canvas cap, quilted with wool, and give him a purging or ſcouring.

FALLING-*ſickneſs*. See EPILEPSY.

Dr. Tuberville, in the Philoſophical Tranſactions, gives the hiſtory of a patient much troubled with the *falling*-ſickneſs, in whoſe urine he obſerved a great number of ſhort worms, full of legs, and like miſſepedes. While theſe continued lively and full of motion, the fits returned daily; but upon preſcribing her half an ounce of oxymel helleboratum in tanſy-water, the worms and the diſtemper were both effectually deſtroyed.

FALLOPIAN *tubes*, in *Anatomy*, two ducts ariſing from the womb, one on each ſide of the *fundus*, and thence extended to the ovaries; having a conſiderable ſhare in conception.

They are called *tubæ*, i. e. *trumpets*, in reſpect of their form; becauſe in their riſe, or opening into the womb, they are exceedingly ſmall, ſo as ſcarce to admit a knitting-needle, but in their progreſs towards the ovaries they grow much bigger, and at length are capable of receiving the finger; from whence they contract again, and at the extremity near the ovaries are expanded into a ſort of foliage, which is fringed round with innumerable little fibres, bearing ſome reſemblance to the mouth of a trumpet.

The *Fallopian* tubes are four or five inches long; they conſiſt of a double membrane, derived from the outer and

and inner membranes of the uterus. The extremity next the ovary, at the time of impregnation, at which time the whole tube is expanded, reaches to, and embraces the ovary; though at other times it seems to fall a little short of it, and is only slightly tied by the fringe to the under side of the ovary.

The use of the tubes is, to convey the seed, or rather ova of women, and other animals, from the testicles or ovaries, into the uterus. See OVARY, and UTERUS.

The inner substance is composed, in good measure, of ramifications of veins and arteries, which form a kind of reticular or cavernous body, not unlike that of the clitoris. This structure makes them capable of dilatation and contraction, according to the quantity and drop of the blood; and consequently of being, as it were, erected in coitu, and of embracing the ovary at that time, which in their state of flaccidity they did not. See GENERATION.

They take their denomination, *Fallopian*, from Gabriel Fallopius, a Modenese, who died in 1562, and who is commonly reputed the first observer of them; though we find them described long before him by Rufus of Ephesus.

The *ova*, or embryoes, are sometimes detained in the *tubæ Fallopianæ*, and cannot make their way into the womb. Instances of this kind have been frequently met with in dissections. One of the most remarkable is that related by Abraham Cyprianus, a celebrated physician of Amsterdam, in a letter addressed to sir Thomas Millington, wherein he describes the manner in which he drew a fœtus, twenty-one months old, out of the tuba of a woman, who lived and had several children after the operation. See *Tab. Anat. (Splan.) fig.* 9. *e e*, and *fig.* 11. *ee*.

FALLOPII *ligamentum*, called also *ligamentum Poupartii*, is the lower border of the tendon of the external oblique muscle of the belly, stretched from the fore-part of the *os ilium* to the pubis.

FALLOW, a name of a pasture red, like that of a brick half burnt; such is that of a *fallow* DEER, &c.

FALLOW-*field*, or *fallow-ground*, is land laid up, or that has lain untilled for a considerable time.

To *fallow*, is to prepare land by ploughing, long before it be ploughed for seed. To do this twice is to *trefallow*, and thrice, to *tresallow*. See PLOUGHING *of fallows*.

FALLOW-*finch*, or FALLOW-*finish*, in *Zoology*, a name of the oenanthe, more commonly called the WHEAT-*ear*, and by some authors *ostfara*.

FALLOW-*cleansing machine*, in *Agriculture*, was invented by Mr. Aaron Ogden, a smith, at Ashton-under-Line, near Manchester, in Lancashire. It is intended for cleansing *fallows* from weeds, &c. which exhaust the riches of the soil. The construction and use of this machine will be understood from the following description, and the figure in *Tab. Agriculture, fig.* 1. A, A, is the frame; B, the first roller; C, the second, ditto, in which last are two cranks to move the arms D, D, which work the rake up the directors fixed on the plank E. The under sides of the lower ends, or shares, of these directors, are sharp to cut the clods, and let them come on the upper side. Each alternate heel of the share is longer than the intermediate one, that they may not have more than one half to cut at once. At the back of the plank E, are two screws to let it loose, that the directors may be set higher or lower. The shares are to penetrate the ground two or three inches, to raise the quicks till the rake f, f, fetches them into the cart H, where a man must be ready with a muck-hook to clear them backward, when gathered. In the rake I, are two teeth for every space of the directors, that stones, &c. may be gathered without damage. K, K, are two dispies, by which the machine is drawn; under them at *h*, are two hooks, placed low to raise the machine in turning, by the help of the traces; and the axle-tree of the cart should be fixed upon a pin, that it may turn like a waggon. F, F, are the triggers to throw the rake behind the roots. The long teeth at G, G, are to cleanse the roller C. l, l, is the rake which gathers up the weeds into the cart H, and is drawn above the trigger F, by the working of the arms D. expressed by the dotted lines at *d d*, *e e*. The triggers F, of which there is one on each side, move on the pivots *a*; so that when the points *b*, of the rake I, have been drawn up by the directors E, to the part marked *c*, the trigger, giving way, permits the rake to pass; but immediately falling, the rake returns along the upper surface of the trigger marked *e*, *e*, and of course falls on the weeds when it comes to the end, a little beyond the pivots *a*. The reader will observe, that the boarding is taken away on one side in the plate, in order to give a more perfect view of the inner parts of the machine; and, in fact, it would, perhaps, be better if all the boarding, marked L, L, L, was taken away, and frame work put in its stead. The cart, H, might undoubtedly also be made lighter. The wheels M, M, appear in the plate, to be made of solid wood; but there is no necessity they should be so. At N, is another view of the roller C, by which the disposition of the spikes may be easily comprehended. Suppose the circle O, described by the end of the roller N, to be divided by four straight lines into eight equal segments, as represented at P. Let the same be done at the other end of the roller, and parallel lines be drawn from one corresponding point to the other, the length of the roller; mark the points with figures 1, 2, 3, 4, 5, 6, 7, 8; afterwards draw oblique lines, as from 1, at the end O, to 2, at the other end, and from 2 to 3, &c. on these oblique lines the spikes are to be fixed, at equal distances, in eight circles, described on the circumference of the roller. The spikes of the small roller B, are fixed in the same manner, except that the diameter being smaller, there are only six instead of eight rows. R, is another view of the directors, with the plank E, on which they are fixed; and S is a section of a part of the plank, with one of the directors as fixed, in which may be seen the heel *m*, from whence to the point of the share *n*, is a sharp cutting edge. See the same letters, in figure R. At T, is one of the long teeth to be seen at G; it is bent towards the roller C, which it serves to cleanse. When the end of the rake *b*, after rising above *c*, is pushed, by the motion of the arms D, D, along the upper part *e*, *e*, of the trigger F, and comes to the end beyond *a*; as it falls, the part of the arm, marked *a*, rests in the notch *b*, till it is again raised by the motion of the roller C, with the rake. The roller C, is to be one foot diameter, the spikes nine inches long, that they may go through the furrow (if the soil should be loose) into the hard earth, the more effectually to work the rake, which otherwise might be so overcharged as to cause the roller to drag without turning. In the rake-ends *b*, there should be sixes, with rollers or pullers on, to go in the grooves, to ease off the frictions; and they would be of use to the triggers, more surely to the rake comes back. The rake should also be hung so far backwards, that when it is pulled, the arms of it may lie in the same plane, or parallel, with the directors, on which it comes up (which will require the frame to be two inches longer in the model.) This will cause the rake to fall heavier, and drive the teeth into the roots, and bring them up without flattering. These teeth must be made of steel, very fine, and so long as to reach down to the plank on which the directors are fixed, that is to say, six inches long (the directors are also to be made six inches broad above the plank). The rake head should also fall a little before the crank is at its extremity, which will cause the rake to push forward to let the teeth come into the roots. The rake-teeth must drop in the same plane with the roller and wheels, or on the surface of the earth. No more space should be given from the roller C, to the long teeth at G G, than that the rake may just miss the spikes of the roller C, and fall on the places before mentioned. As the first roller B, was intended to cleanse the second C, more than for any other use, it may be omitted when the machine is made in large; as Mr. Ogden has lately found that the long teeth at G, G, answer the end alone, and this renders the machine about a sixth part shorter. Now, to suit any sort of earth, there should be to each machine three planks, with directors at different spaces, to suit occasionally; in the first, the spaces between the directors should be eight inches wide, in the second six, and the third four. This will answer the same end as having so many machines.

As there may be some objections to the rake not tearing the roots when it has brought them up, Mr. Ogden has several methods of cleansing it; but as he would make it as simple as possible, he chuses to let it be without them at present; but suppose it should bring some roots back again with it, it will probably lose them before it gets back to the extremity; whence they will lie light, and be of but little detriment to the others coming up.

Mr. Ogden would have the first machine made four feet six inches wide, the teeth divided into equal spaces, the outsides into half spaces.

FALLOW-*hounds*. See HOUNDS.

FALLUM, in some of our *Latin Lexicographers*, is said to be a sort of land; and for proof of this they quote the Mosaicon Anglicanum. *De duobus acris & tribus fallis in, &c.* Jacob. But from this passage it would rather seem that *fallum* signified a measure of land, as well as *acra*. And to this day a FALL is a measure of length in Scotland.

FALSE *alarm*, in *War*, a feigned, or a mistaken ALARM.

FALSE *arms*, in *Heraldry*, are those wherein the fundamental rules of the art are not observed; as if metal be put on metal, or colour on colour. See *Arms*.

FALSE *attack*, in *War*. See ATTACK, *false*.

FALSE *arms*, in *Fortification*. See FAUSSEBRAIE.

FALSE *claim*, in the *Forest Laws*, is where a man claims more than his due, and is amerced or punished for the same.

FALSE *conception*. See CONCEPTION.

FALSE *flower*, a flower which does not seem to produce any fruit, as those of the hazel, mulberry-tree, &c.

A FLOWER of this kind does not arise from any embryo, and does not knit; such are the male flowers of the melon, cucumber, &c.

FALSE *galena*. See BLIND and GALENA.

FALSE *gallop*, in the *Manege*. See GALLOP.

FALSE *imprisonment*, is a trespass committed against a man, by imprisoning him without sufficient authority; which authority may arise either from some process from the courts of justice, or from some warrant from a legal officer, having a power to command, under his hand and seal, and expressing the cause of such commitment; or from some other special cause, warranted on account of the necessity of the thing, either by common law, or act of parliament; such as the arresting of a felon by a private person without warrant, the impressing of mariners for the public service, or the apprehending of waggoners for misbehaviour in the public highways. Stat. 7 Geo. III. cap. 42. *False* imprisonment also may arise by executing a lawful warrant or process on an unlawful day, as on a Sunday. stat. 29 Car. II. cap. 7. or in a place privileged from arrests, as in the verge of the king's court. The means of removing the actual injury of *false* imprisonment are fourfold; viz. by a writ of MAINPRIZE, by writ *de odio & atia*, by writ *de* HOMINE *replegiando*, and by writ of HABEAS *corpus*. The satisfactory remedy for this injury is by an action of trespass, *vi & armis*, usually called an action of *false* imprisonment; which is generally, and almost unavoidably, accompanied with a charge of assault and battery also; and therein the party shall recover damages for the injury he has received; and also the defendant is, as for all other injuries committed with force, or *vi & armis*, liable to pay a fine to the king for the violation of the public peace.

FALSE *judgment*. See FALSO *judicio*.

FALSE *keel*, in a ship, is a second keel, which is sometimes put under the first, to make the vessel deeper, and to preserve the lower side of the main keel. In our largest ships of war, the *false* KEEL is generally composed of two pieces, which are called the upper and the lower *false* keels. See *Tab. Ship. fig.* 2. *n.* 54. and *n.* 118.

FALSE *muster*, is when such men pass in review, as are not actually listed as soldiers. See FAGGOT, &c.

FALSE *news*, *spreading of*, in order to make discord between the king and nobility, or concerning any great man of the realm, is punishable by common law with fine and imprisonment; which is confirmed by Statutes Westm. 1. 3 Edw. I. cap. 34. 2 Ric. II. stat. 1. cap. 5. & 12 Ric. II. cap. 11.

FALSE *oath*. See PERJURY.

FALSE, or *falſe poſition*, in *Arithmetic*. See POSITION.

FALSE *prophecies*. See PROPHECIES.

FALSE *quarters of a horſe*. See *Falſe* QUARTERS.

FALSE *ribs*. See *Spurious* RIBS.

FALSE *roof of a houſe*, is that part between the upper room and the covering.

FALSE *return*. On a *falſe* return by a mayor, &c. to a mandamus, or by a sheriff, &c. to a writ, a special action on the case will lie.

FALSE *root*, is that of which the value is negative. E. gr. in the equation $a^2 + b^2 = x^2$, if x be a negative quantity as -5, the *root* is said to be *falſe*, if it be a positive quantity, it is called a real or true *root*; if it be the *root* of a negative quantity, it is said to be imaginary; as $\sqrt{-5}$.

FALSE *ſheat*, on board a ship. See SHEAT.

FALSE *ſtem*, in a ship. See STEM.

FALSE *tokens*, in *Law*, is used where persons get money or goods into their hands by forged letters, or other counterfeit means. This is punishable by imprisonment by stat. 33 Hen. VIII. cap. 1. By 30 Geo. II. cap. 24. a further penalty is inflicted on those who obtain money or goods by false tokens and pretences. See CHEATS.

FALSE *tone*, in *Muſic*. Some call the INTERVAL of two semi-tones major by this name; but others more properly call it diminished third.

FALSE *verdict*. See ATTAINT.

FALSE *weights*. See WEIGHTS.

FALSHOOD, FALSITY, in *Philoſophy*, an act of the understanding, representing a thing otherwise than it is, as to its accidents; or falſe enumeration, or judgment of any thing.

The circumſtance, as to its accidents, is of abſolute neceſſity in the definition, becauſe a thing cannot be repreſented otherwiſe than it is as to eſſentials; for in ſuch caſe the eſſence of the thing would not be repreſented; and ſince the eſſence is the thing itſelf, it would not be that thing which is repreſented, but another.

There is no *falſhood* in apprehenſion or imagination; our ideas of ſenſe are all juſt and true, *in ſo far as* they go; and all our deluſions ariſe from our reaſonings and concluſions from them.

FALSI *Crimen*, in the *Civil Law*, is a fraudulent ſubornation or concealment, with deſign to darken or hide the truth, and make things appear otherwiſe than they are.

The *crimen falſi* is committed three ways. By words, as when a witneſs ſwears falſly. By writing, as when a man frames or alters ſomething, antedates a contract, or the like. See FORGERY. And by deed, as when he falſifies by falſe weights and meaſures, debaſes the coin, &c.

FALSIFY, in *Law*, is uſed for proving any thing to be falſe. Hence we find

FALSIFYING *a record*, for ſhewing it to be erroneous. Thus lawyers teach, that a perſon purchaſing land of another, who is afterwards outlawed of felony, &c. may *falſify* the record, not only as to the time wherein the felony is ſuppoſed to have been committed, but alſo as to the point of the offence. But where a man is found guilty by verdict, a purchaſer cannot *falſify*, as to the offence; though he may, for the time where the party is found guilty generally in the indictment, becauſe the time is not material upon evidence. 2 Hawk. Pl. Crown, 459. We alſo meet with

FALSIFYING *a recovery*. Thus, it is ſaid, the iſſue in tail may *falſify* a recovery ſuffered by a tenant for life, &c.

FALSO *bordone*, in the *Italian Muſic*, is uſed to denote the burden or ground-baſs of a ſong, when it is not exact to the rules of harmony, i. e. when the notes move all the ſame way, as is often the caſe in the Pſalms, and other parts of divine office. The name is more particularly given to a certain harmony produced by the accompaniments of ſeveral ſixths following one another, which make ſeveral fourths between two higher parts; becauſe the third part is obliged to make thirds with the baſs.

FALSO *judicio*, a writ which lies for falſe judgment, given in the county court, court-baron, or other court, not of record.

FALSO *return brevium*, a writ which lies againſt the ſheriff, who has execution of proceſs, for making falſe returns of writs.

FALUN, a word uſed in many parts of France, as the name of a particular ſort of manure of lands, which is dug out of the earth, and is no other than fragments of ſea-ſhells buried at conſiderable depths, and amaſſed in prodigious ſtrata in many parts of that kingdom. Theſe they ſpread on the lands in the manner of dung; and being as it were calcined and very friable, they readily diſſolve, and are the fineſt manure of any for ſome ſoils.

FALX, in *Anatomy*, a part of the dura mater, deſcending between the two hemiſpheres of the brain, and ſeparating the fore-part from the hinder.

It is called *falx*, i. e. *ſickle*, becauſe of its curvature, occaſioned by the convexity of the BRAIN. It divides the brain as low as the corpus calloſum.

FALX, the *ſickle-fiſh*, in *Ichthyology*, a ſmall fiſh of the tenia kind, common about the ſhores of the Mediterranean, but ſeldom brought to ſale, becauſe of its glutinous nature, being wholly converted into a ſort of glue, when dreſſed. It is a ſoft and ſmooth oblong fiſh, and has its name from reſembling a ſickle in figure. It is often found an ell long, and with that length is not above the breadth of one's hand. It is of a silvery colour, but its back-fin is red. Its eyes are large, and its head very ill ſhaped. The common people call it the marmot-fiſh.

FAMES *canina*, by the Greeks called *cynodes orexis*, q. d. *dog-appetite*, is ſuch an inſatiable hunger as is not to be ſatisfied with eating, but continues even when the ſtomach is full.

This is a caſe much talked of by the ancients, and ſometimes met with amongſt us. It may be ſuppoſed to ariſe from ſharp fretting juices in the ſtomach, which by their continued vellications excite a ſenſe like that of hunger. See BULIMY.

FAMILIA, FAMILY, commonly implies all the ſervants belonging to a particular maſter.

In another ſenſe, *family* is taken for a portion of land, viz. ſo much as is ſufficient to maintain one *family*.

The term HIDE is by our writers ſometimes rendered a meaſure, ſometimes a *family*, and ſometimes *carucata*, or plough-land; containing as much as one plough and oxen could cultivate in a year.

FAMILIA, in *Natural Hiſtory*, a term uſed by authors to expreſs a certain order of animals, or other natural productions, agreeing in their principal characters, and containing numerous individuals, not only different from one another, but in whole ſets, ſeveral numbers being to be collected out of the ſame family, all of which

have the *family* characters, and all those subordinate distinctions peculiar to that whole number; or though found in every individual of it, not found in those of any others.

It has been too common to confound the words, class, *family*, order, &c. in natural history. But the determinate meaning of the word *genus* seems to be that larger order of creatures, under which classes and genera are subordinate distinctions. Among the quadrupeds, the several genera of the unguiculated creatures agree one with another in many general characters common to all; and in which they differ from the ungulated animals, which have also their several peculiar characters common to all, and yet different from all those of the others. These naturally constitute certain larger divisions into *families*, and no one would ever break through these, or bring the cat and the horse into the same *family*.

In the same manner, in *lithology*, there are several genera of stones, which agree perfectly in certain common characters, and disagree from all others in them.

The arrangement of natural bodies into these *families*, or general and larger classes, is of the utmost use to natural history, when it is properly done, and the divisions are genuine and natural; when otherwise, it is hurtful.

These divisions of animals into families are of two kinds, the one artificial or hypothetical, the other natural.

FAMILIARS *of the Inquisition*, persons who assist in apprehending such as are accused, and carrying them to prison. They are assistants to the inquisitor, and called *familiars*, because they belong to his family. In some provinces in Italy they are called cross-bearers, and in others the scholars of St. Peter the Martyr; and they wore a cross before them on the outside garment. They are properly bailiffs of the inquisition; and the vile office is esteemed so honourable, that noblemen in the kingdom of Portugal have been ambitious of belonging to it. Nor is this surprising, when it is considered that Innocent III. granted very large indulgences and privileges to these *familiars*; and that the same plenary indulgence is granted by the pope to every single exercise of this office, as was granted by the Lateran council to those who succoured the Holy Land. When several persons are to be taken up at the same time, these *familiars* are commanded to order matters, that they may know nothing of one another's being apprehended: and it is related, that a father and his three sons, and three daughters, who lived together in the same house, were carried prisoners to the inquisition without knowing any thing of one another's being there till seven years afterwards, when they that were alive were released by an act of faith. Geddes's Tracts, vol. i. p. 425—429. Limborch's Hist. of the Inquis. by Chandler, p. 187.

FAMILY *of cards*. See *Family of* CURVES.

FAMILY *of love*, in *Ecclesiastical History*, the name of an anabaptist sect, founded in Holland, in 1555, by Henry Nicholas, a Westphalian. This deluded fanatic maintained, that he had a commission from heaven to teach men, that the essence of religion consisted in the feelings of divine love; that all other theological tenets, whether they related to objects of faith, or modes of worship, were of no moment; and that it was a matter of perfect indifference what opinions Christians entertained concerning the divine nature, provided their hearts burned with the pure and sacred flame of piety and love. Dr. Henry More wrote against this sect, in his Grand Explanation of the Mystery of Godliness, book *vi.* chap. 12—18. George Fox, the founder of the sect of quakers, also exposed them, and called them a motley tribe of fanatics, because they took oaths, danced, sung, and made merry. The principles of this sect were propagated in England, and produced no small confusion. The form of abjuration tendered to them, and the severe proclamation issued against them by queen Elizabeth, in 1580, may be seen in Wilkins's Concilia Magnæ Brit. &c. vol. iv. p. 296, 297.

FAN, *Flabellum*, a machine used to raise wind and cool the air by agitating it.

The effect of fanning ourselves, when warm, in order to cool us, though the air is itself warm, which we drive with the *fan* upon our faces, may be thus explained: the atmosphere round, and next to our bodies, having imbibed as much of the perspired vapour as it can well contain, receives no more, and the evaporation is therefore checked and retarded till we drive away that atmosphere, and bring drier air in its place, that will receive the vapour, and thereby increase and facilitate the EVAPORATION, and thus contribute to cool us.

That the use of the *fan* was known to the ancients, is very evident from what Terence says,

Cave hoc flabellum, *& verecundum hoc fac facias*;

and from Ovid, Art. Amand. i. 161.

Prosint & tenuis ventis movisse flabello.

The *fans* of the ancients were made of different materials; but the most elegant were composed of peacock's feathers, or perhaps painted, so as to represent a peacock's tail.

The custom which now prevails among the ladies, of wearing *fans*, was borrowed from the East, where the hot climate renders the use of *fans* and umbrellas almost indispensable.

In the East they chiefly use large *fans* made of feathers, to keep off the sun and the flies. In Italy and Spain they have a large sort of square *fans*, suspended in the middle of their apartments, and particularly over the tables: these, by a motion at first given them, and which they retain a long time, on account of their perpendicular suspension, help to cool the air, and drive off flies.

In the Greek church, a *fan* is put into the hands of the deacons in the ceremony of their ordination, in allusion to a part of the deacon's office in that church, which is to keep the flies off the priests during the celebration of the sacrament.

Wicquefort, in his translation of the embassy of Garcias de Figueroa, gives the name *fans* to a kind of chimneys or wind-sails in use among the Persians, to furnish air, and wind, into their houses; without which the heats would be insupportable. What is called a *fan* amongst us, and throughout the chief parts of Europe, is a thin skin, or piece of paper, taffety, or other light stuff, cut semicircularly, and mounted on several little sticks of wood, ivory, tortoise-shell, and the like.

If the paper be single, the sticks of the mounting are pasted on the least ornamental side: if double, the sticks are placed betwixt them. Before they proceed to place the sticks, which they call *mounting the fan*, the paper is to be plaited in such manner, as that the plaits may be alternately inward or outward.

It is in the middle of each plait, which is usually about half an inch broad, that the [illegible] and these again are to be al[illegible] together at the other end; they are very thin, and [illegible] exceed one third of an inch in breadth; and where they are pasted to the paper, are still narrower, continuing thus to the extremity of the paper. The two outer ones are bigger and stronger than the others. The number of sticks rarely exceeds twenty-two. The sticks are usually provided by the cabinet-makers or toy-men; the *fan*-painters plait the papers, paint, and mount them.

The common painting is either in colours or gold leaf, applied on a silver ground, both prepared by the gold-beaters. Sometimes they paint on a gold ground, but it is rarely; true gold being too dear, and false too paltry. To apply the silver leaves on the paper, they use a composition, which they pretend is a great secret, but which appears to be no other than gum Arabic, sugar-candy, and a little honey melted in common water, and mixed with a little brandy. This composition is laid on with a sponge; then laying the silver leaves thereon, and pressing them gently down with a linen ball stuffed with cotton, they catch hold, and adhere together. When, instead of silver, gold ground is laid, the same method is observed.

The ground being well *dried*, a number of the papers are well beaten together on a block, and by this means the silver or gold get a lustre, as if they had been burnished.

FAN is also an instrument to winnow corn. See WINNOW.

FAN, *fan*. See GORGONIA.

FANATIC, a wild, extravagant, visionary, enthusiastical person; who pretends to revelation and inspiration, and believes himself possessed with a divine spirit.

The word is formed of the Latin *fanum*, a *heathen temple*; for which reason the Christians called all the Gentiles *fanatics*; and accordingly the ancient chronicles of France called Clovis, *fanatic* and Pagan.

Among the Heathens themselves, there were a sort of prophetic priests, called *fanatici*; from whom the denomination since passed to all the rest. They had their name from the Latin *fanum*, *temple*, because they lived all together in temples. Struv. Antiq. Rom. Sent. cap. 6. p. 312.

Of this kind particularly were the priests of Isis, of the mother of the gods, of Bellona, and some others, who were called *fanatici*. In Gruter, p. 312. n. vii. we have an inscription, wherein one L. Cornelius Januarius is called *Fanaticus*, AB. ISIA. SERAPIS. ADAEDEM BELLONE. And, p. 645. n. vii. *Fanaticus de æde Bellonæ*. What might give occasion to the appellation of *fanatics* was, that they performed their sacrifices in a wild, enthusiastical manner; and the appellation has been generally applied in modern times to those who have made pretences to inspiration, and who have conducted their worship or practice in an extravagant and licentious manner. Such were some of the German anabaptists and

English quakers, at their firſt riſe, and the modern prophets, Muggletonians, Behmeniſts, &c. And the name *fanatics*, as well as ſectaries, has been generally and invidiouſly applied to diſſenters from the church of England. See SUPERSTITION.

FANATIO, in our *Ancient Cuſtoms*, the fawning time, or RENCE-months in foreſts.

FANCY. See PHANTASY, and IMAGINATION.

FANIONS, in *Military Language*, ſmall flags carried along with the baggage. See FLAG.

FANTASIA, in the *Italian Muſic*, ſignifies *fancy*, and is uſed for a compoſition, wherein the compoſer ties himſelf to no particular time, but ranges according as his fancy leads, amidſt various movements, different airs, &c. This is otherwiſe called the *capriciouſo ſtile*: before ſonatas were uſed there were many of this kind, ſome of which remain even now.

FANTASTICAL *colours*, are the ſame with thoſe called EMPHATICAL *colours*.

FANTOME *corn*, in *Huſbandry*, a term uſed by the farmers in ſome of our counties for lean, light, and tank corn; as they call in the ſame places *fantome* ſheep, that which is lean and poor, and can hardly hang on the bones.

FANUM, among the Romans, a temple or place conſecrated to ſome deity. The deified men and women among the heathens had likewiſe their *fana*; even the great philoſopher Cicero erected one to his daughter Tullia. Mem. Acad. Inſcrip. vol. i. p. 488, *ſeq.*

FAPESMO, in *Logic*, one of the moods of ſyllogiſms.

A ſyllogiſm in *fapeſmo* has its firſt propoſition an univerſal affirmative, the ſecond an univerſal negative, and the third a particular negative.

FAQUIR. See FAKIR.

FAR, in *Huſbandry*, an appellation given to any horſe's right ſides: thus we ſay *far* foot, the *far* ſhoulder, &c. as the ſame way the right ſide is called, right ſhoulder, &c.

FARANDMAN, in our *Old Writers*, a traveller or merchant ſtranger, to whom by the law of Scotland juſtice ought to be done with all expedition, that his buſineſs or journey be not hindered.

FARCE was originally a droll, petty ſhew, or entertainment, exhibited by charlatans, or quacks, and their buffoons, in the open ſtreet, to gather the croud together.

The word is *French*, and ſignifies literally, *force-meat* or *ſtuffing*. It was applied on this occaſion, without doubt, on account of the variety of ſkits, jibes, tricks, &c. wherewith the entertainment was interlarded. Some authors derive *farce*, from the Latin *faceties*; others from the Celtic *farc*, *mockery*; others from the Latin *farcire*, *to ſtuff*.

At preſent, *farce* is of a little more dignity. It is removed from the ſtreet to the theatre; and inſtead of being performed by merry-andrews, to amuſe the rabble, is now acted by our comedians, and become the entertainment of the politeſt audiences.

The poets have reformed the wildneſs of the primitive *farce*, and brought them to the rules and manner of comedy. The difference between the two on our ſtage, is, that the latter keeps to nature and probability; and, in order to that, is confined to certain laws, unities, &c. preſcribed by the ancient critics.

The former diſdains all theſe laws, or rather ſets them all aſide on occaſion. Its end is purely to pleaſe, or to make merry; and it ſticks at nothing which may contribute thereto, however wild and extravagant. Hence the dialogue is uſually low, the perſons of inferior rank, and the fable or action trivial or ridiculous; and nature and truth are every where heightened and exaggerated to afford the more palpable ridicule.

FARCIMINALIS *Tumor*, the ſame with ALLANTOIS.

FARCIN, FARCY, or FASHIONS, a diſeaſe in horſes, and ſometimes in oxen, &c. ſomewhat of the nature of a ſcabies or mange.

Gefner derives the word from *varices*, by changing the *v* into a digamma or *f*.

The *farcin* is infectious, and ſpreads like a true plague. Vegetius calls it *morbus ſarcinoſus*. It conſiſts in a corruption of the blood, which ſhews itſelf in eruptions of hard puſtules, knots, or ſtrings along the veins, and in ulcers, which are not cured without great difficulty, by running from irons into them.

There is a *ſpreading farcin* which *diffuſes* itſelf over the whole body; an *inner farcy*, a *ſtringed farcy*, &c.

The *farcy* is ordinarily occaſioned by exceſſive heats and colds, ſometimes by ſpur-galling with ruſty ſpurs, ill-faſhioned bits, or the like; or by the bite of another horſe infected with it; or if in the *leg*, by cutting or interfering.

For the cure, firſt bleed the horſe well; then give him four ounces of cream of tartar and lenitive electuary made into balls every other day for a week; and then give him three ounces of nitre every day for three weeks or a month; and anoint the buds and ſwelling twice a day with the following ointment, viz. ointment of elder, four ounces; oil of turpentine, two ounces; ſugar of lead, half an ounce; white vitriol powdered, two drams; and let theſe ſeveral ingredients be mixed together in a galley-pot. By this proceſs the tumours will ſometimes diſperſe; but if they break and diſcharge a well-digeſted matter, they will ſoon be well, by giving liver of antimony in the quantity of two ounces a day for a fortnight, and one ounce a day for another fortnight. This will be the caſe when the diſeaſe affects only the ſmaller veſſels; but if it affects the larger blood-veſſels, the cure will be more difficult. When the plate, thigh, or neck-veins appear chorded, bleed immediately on the oppoſite ſide, and apply to the diſtempered vein the following compoſition, viz. ſix ounces of oil of turpentine, and three ounces of oil of vitriol: the oil of vitriol muſt be dropped gently into the turpentine-oil, or elſe the bottle in which it is contained will burſt. Let the diſeaſed parts be firſt rubbed with a woollen cloth, and then apply ſome of this mixture twice a day. Let the cooling phyſic and nitre, and liver of antimony be uſed, as above directed; and let the ſores be dreſſed with bees-wax and oil.

If the diſeaſe is ſituated near the flanks and lowes belly, and does not yield to the compound oil, it may be neceſſary to bathe the parts with the following mixture as far as the centre of the belly, and to give a courſe of antimonial medicines. Take four ounces of ſpirit of wine; oil of vitriol and turpentine, of each two ounces; white wine vinegar, or verjuice, ſix ounces. When the diſtemper becomes inveterate, notwithſtanding the preceding application, Gibſon recommends the following mixture, viz. half a pint of linſeed oil; oil of turpentine and nitre, of each three ounces; tincture of euphorbium and hellebore, of each two drams; the ſoldier's ointment, or oil of bays, two ounces; oil of origanum, half an ounce; double aqua fortis, half an ounce: when the chriſtalliſation is over, add two ounces of Barbadoes tar. With this mixture rub the tumors and chorded veins once or twice in two or three days, opening a paſſage to the matter iſſuing from the ulcers if they are choaked up, with a ſmall hot iron, and deſtroying with vitriol the proud fleſh, which may be kept down by touching with oil of vitriol, aqua fortis, or butter of antimony. Dr. Bracken recommends the mercurial ointment for rubbing the chords and tumors before they break, in order to diſperſe them; and when they are broke, to dreſs the ſores with equal parts of Venice turpentine and quickſilver. Mercurials have been likewiſe given internally in various ways; two ounces of quickſilver divided with an ounce of turpentine, and made up into four balls with diapente and gum guaiacum, of each two ounces, with a ſufficient quantity of honey, have been ſucceſsfully given in the quantity of one ball twice a week: but when mercurials are adminiſtered either internally or externally, gentle purgatives ſhould be interpoſed to prevent a ſalivation.

The *water-farcin*, which is a kind of dropſy, proceeds from a horſe's feeding on low watery grounds, and in pits or holes where the graſs grows above the water; for the horſe in picking out the graſs licks up the water, which occaſions him to ſwell under the belly or thighs.

The *water-farcin* is of two kinds; one produced by a ſeverith diſpoſition, terminating on the ſkin; and the other a true dropſy, in which the water is not confined to the belly and limbs, but is found in different parts of the body, where a great number of ſoft ſwellings appear, which yield to the preſſure of the finger. The firſt ſpecies may be relieved by ſlight ſcarifications in the inſide of the leg and thigh with a ſharp penknife; but in the other ſpecies the water muſt be diſcharged and the craſis of the blood recovered by a purge given every week or ten days, and immediately after the firſt the following balls: take of nitre, two ounces; ſquills powdered, three drams, or half an ounce; camphor, one dram, and a ſufficient quantity of honey to bring them of a due conſiſtence for balls. This ball ſhould be given once a day, and waſhed down with a horn or two of the following drink: take of black hellebore, freſh gathered, two pounds; walls, bruiſe, and boil it in ſix quarts of water till it is reduced to four; ſtrain off the liquor, and pour on the remaining hellebore two quarts of white wine; place it in a gentle heat, and let it infuſe forty-eight hours; ſtrain it off, and mix both together, and give the horſe a pint night and morning. When the horſe begins to recover, complete the cure by giving him half a pint of the following infuſion every night and morning for a fortnight, and let him faſt two hours after it: take gentian-root and zedoary, of each four ounces; chamomile-flowers and the tops of centaury, of each two handfuls; of jeſuit's bark, powdered, two ounces; of juniper-berries, four ounces; of ſhings of iron, half a pound; infuſe the whole in two gallons of ale for a week, ſhaking the veſſel often.

We have in the Philoſophical Tranſactions an account of

a horſe

a horſe being cured of this diſeaſe by hemlock. The diſcovery was accidental; the maſter of the horſe riding near a place where hemlock grew abundantly, ſuffered his horſe to eat greedily of it, and he became better from that time, and in a few days was wholly cured. We generally eſteem hemlock a poiſon; but beſide this proof of its ſalutary effects, it is well known that its ſeeds are eaten by ſome birds, particularly by the buſtards, in very great quantities, without any harm.

FARDEL *of Land*, is, according to ſome authors, the fourth; according to Noy, only the eighth part of a yard-land. See YARD-LAND.

Decem acræ faciunt ferdellam, *quatuor ferdellæ faciunt* virgatam, *& quatuor virgatæ faciunt* hidam, *& quatuor hidæ faciunt* feudum *militare*.

FARDING-*Beg*, the firſt ſtomach of a cow or other ruminating animal.

FARDING-*deal* or FARDING-LAND, in our *Antient Cuſtoms*, ſignifies the fourth part of an acre, now called a *rood*. In the regiſter of writs we have alſo *denariata, obolata, ſolidata*, and *librata terra*, which muſt probably riſe in proportion of quantity from the *farding-deal*, as an half-penny, penny, ſhilling, and pound, riſe in value; on which footing *denata* muſt be half an acre; *denariata*, an acre; *ſolidata*, twelve acres; and *librata*, twelve ſcore acres.

You we find *octoginta libratæ terræ, vel circiter*. Reg. fol. 94. *a*. and 284. *b*. where *librata terræ* ſhould ſeem to be as much as yields 8*l*. 1*s*. *per annum*; and *centum ſolidatas terræ cum, tenementis, & redditibus*, fol. 249. *a*. Others hold *obolata* to be but half a perch, and *denariata* a perch.

FARDINGDEL was the fourth part of a yard-land, or of a ploughland, according to Spelman.

FARE, a voyage or paſſage, or the money paid for paſſing by water, *&c.*

For the *fare* of hackney-coachmen, watermen, *&c.* ſee *Hackney*-COACHES, and WATERMEN.

FARE *of pigs*, the number which a ſow brings forth at one time.

FAREN, in *Ichthyology*, a name given by the Swedes to a fiſh peculiar to their country. It is of the genus of the *cyprini*, and is diſtinguiſhed by Artedi by the name of the *yellow eyed cyprinus*, with twenty-ſeven bones in the *pinna ani*.

FARFARA, a name given by ſome of the ancient *Botaniſts* to the plant we call COLT'S-*foot*, from the river Farfarus, mentioned by Ovid as remarkable for its ſhady banks, which afforded a very large quantity of this plant. Pliny mentions this plant with much confuſion, calling it alſo *farfara* and *farfugio*, and ſuggeſting that he had before deſcribed it under the name of *tuſſilago* or bechion.

FARFRUGUM, in *Botany*, a name by which ſome authors have called the caltha paluſtris, or *marſh* MARYGOLD.

FARFUGIUM, in *Botany*, a name by which ſome authors call COLT'S-*foot*.

FARINA, the flour or powder of ſome ſort of grain or pulſe, ground and ſifted from the bran.

The word is formed of *far, corn-wheat*; and *fer*, according to Guichard, comes from the Hebrew, ⁊⁊, *bar*, ſignifying the ſame thing.

FARINA *fœcundans*, or *pollen*, among *Naturaliſts*, is a fine duſt prepared in the male flowers, or the male parts of flowers of plants; which, being afterward ſhed on the female, does the office of a ſperm or ſemen, by impregnating the ſame.

The *farina fœcundans*, called alſo the *male duſt* and *male ſeed*, is formed and ſecreted in the apices or anthers of the ſtamina; where, when it becomes mature and copious enough, burſting its capſula, it is ſpit on the head of the piſtil, and thence conveyed to the matrix or uricle thereof, to fecundify the ova or female ſeed contained therein.

This duſt in any one plant being viewed with a microſcope, every particle thereof appears of the ſame ſize, and figure; but in different plants the figure, ſize, colour, *&c.* of the duſt are very different.

It may be obſerved, however, that the colour of the *farina* varies in the ſame ſpecies, according to the colour of the flower; and even ſometimes the *farina* of the ſame flower is of different colours, as is eaſily obſerved in the caryophyllus arvenſis.

The figures of the divers kinds of *farina* are much harder to deſcribe. The moſt general figure is the oval, more or leſs ſharp at the ends, with one or more channels or furrows running lengthwiſe; ſo that through the microſcope they look not unlike the ſtone of a date, a grain of wheat, a coffee-berry, or an olive.

The manner of gathering and preſerving the *farinæ* of plants for microſcopic obſervations is this: gather the flowers in the midſt of a dry ſunſhiny day, when the dew is perfectly off; then gently ſhake off the *farina*, or lightly bruſh it off with a ſoft hair-pencil upon a piece of white paper; then take a ſingle tale or iſinglaſs between the fingers, and breathing on it, apply it laſt only to the *farinæ*, the moiſture of the breath will make that light powder ſtick to it. If too great a quantity be found adhering to the tale, blow a little of it off; and if there be too little, breathe on it again, and take up more. When this is done, put the tale into the hole of a ſlider, and applying it to the microſcope, ſee whether the little grains are laid as you deſired and if they are, cover them with another tale, and ſet the things by: but be careful that the tales do not preſs upon the *farinæ*, ſo as to alter its form. Baker's Microſcope, p. 237.

For the appearances of the *farinæ* of a great many plants, ſee *York, of Muſeum ſpiritual Objects, Chap. 1.*

Of *farinæ* ſome are very hard, others ſoft, and eaſily broken. They all contain a great deal of ſulphureous matter more than the other parts, whence they are very odorous. Thoſe of the lilly are ſo full of oil that they greaſe the paper they are put in as if it had been oiled. The *farinæ* of moſt aromatic plants ſwim in an eſſential oil, or ſort of liquid turpentine; others are involved in a dry reſin, as thoſe of the lycopodium or muſcus terreſtris clavatus. Others, as thoſe of ſumitory, are incloſed in a little, viſcid, mucilaginous matter; and all, in general, have ſomething of glutinous, that they ſtick to any thing that touches them, ſo that it is difficult to ſeparate the grains from each other.

Mr. Bradley ſuppoſes a magnetic virtue lodged in the *farina fœcundans* or *male duſt*, by means whereof, when depoſited in the uricle of the female, it draws the nouriſhment from the other parts of the plant into the ova or rudiments of the fruit, and makes them ſwell. The reality of this virtue, he argues, from the ſame being found in wax, which is chiefly or wholly gathered [illegible] by the bees.

The *farina* of plants has [illegible] by ſome an effect upon neighbouring [illegible] ſettings changed by the [illegible] and we have obſervations [illegible] of different colours infecting one another in the ſame manner. Phil. Tranſ. N° 477. 67.

This duſt was for many ages looked upon as an excrement of the plant; but it has of later times been found to conſiſt wholly of organical bodies, which are in reality the embryo-plants; and entering into the ſeeds into the capſules, while yet buried in the Ryle, they fecundate them, and put them in a ſtate to vegetate and produce their ſpecies. On the moſt accurate examination, however, with microſcopes, the *farina* or *pulvis fœcundans* of plants has never been found to carry any rudiments of *plantula ſeminalis*, or the rudiment of the plant which was to be produced by it. All that the microſcope does in this caſe is but increaſing the apparent magnitude of the particles of the powder; but they are found, when thus viewed, to be no other than a congeries of globules, which are all alike in the ſame ſpecies, and compoſed of fibres and veſicules wrought together in ſuch a curious manner to the keeping whole as long as neceſſary, and burſting when neceſſary, that it appears evident they are deſigned for ſome very great uſes.

Vaillantius, in the Acta Eruditorum, has given a very curious detail, and has figured and deſcribed fifty kinds of this duſt, moſt of which are conſiderably different from one another, though ſome are nearly alike. He obſerves, that in all the number of flowers that he examined he found no *farina* or *pulvis fœcundans*, that did not reſemble one of theſe fifty; and that therefore, whoever engages in this curious reſearch, ſhould firſt obſerve theſe, and then refer the others to one or other of them as they next approach them, and mention their differences, if any, by way of characters by which they might always be known. Act. Eruditor. ann. 1724. p. 410.

The author of theſe curious obſervations has given good figures of theſe and of the other of the fifty of his *farinæ* to which we refer the reader. *See Generation of* PLANTS.

FARINAGIUM, in our *Old Writers*, denotes toll of meal or flour.

FARIO, in *Ichthyology*, a term for RAINBOW when about half grown, after it is paſt the ſtate in which it is called a *ſolar*, and before it is of the full growth.

FARLEU, money paid by tenants in the weſt of England in lieu of a heriot. In ſome manors of Devonſhire, *farleu* is often diſtinguiſhed to be the beſt goods, as heriot is the beſt beaſt payable at the death of a tenant.

FARM, or FERM, *firma*, in *Law*, ſignifies a little country meſſuage or diſtrict, containing houſe and land, with other conveniences, hired or taken by leaſe, either in writing or by word, under a certain yearly rent.

This in divers parts is called differently; in the North, it is a *tack*; in Lancaſhire, a *ſtenchel*; in Eſſex, a *wike*. In the corrupted Latin, *firma* ſignifies a place incloſed or ſhut up; whence, in ſome provinces, Menage obſerves,

serves, they call *dolaria* or *doferia*, what in others they call *farm*.

Spelman and Skinner derive the word *farm* from the Saxon, *feorme*, or *feorme*; that is, *victus*, or *provifion*, because the country-people and tenants anciently paid their rents in victuals and other neceſſaries, though this was afterwards converted into the payment of a ſum of money. Whence a *farm* was originally a place that furniſhed its owner or lord with proviſions. And among the Normans they ſtill diſtinguiſh between *farm* that pay in kind; i. e. proviſions; and thoſe which pay in money, calling the former ſimply *fermes*, and the latter *blanche ferme*, *white farm*.

Spelman ſhews, that the word *firma* anciently ſignified not only what we now call a *farm*, but alſo a feaſt or entertainment which the farmer gave the proprietor or landlord for a certain number of days, and at a certain rate, in conſideration of the ſame, &c. be held of him.

Thus *feorm*, in the laws of King Canutus, is rendered by Mr. Lombard, *victus*; and thus we read of *reddere firmam unius noctis*, and *reddere unam diem de firma*, which denote proviſion for a night and day, the rents about the time of the Conqueſt being all reſerved in proviſions; the cuſtom whereof is ſaid to have been firſt altered under Henry I.

It is commonly allowed that a *farm* ſhould make three rents, as they expreſs it, one for the landlord, one for the charges, and one for the farmer to live upon; but it is very ſeldom that a *farm* will continually do this, or is to be maintained at that charge. In a *farm* of one hundred pounds a year, if the land is worth twenty ſhillings an acre, a hundred pounds may defray the charges of it; but if in a *farm* of the ſame rent the land be worth but ten ſhillings an acre, a hundred and thirty pounds a year muſt be allowed for the charges of this, or nearly ſo, and two hundred and fifty acres of ſuch land muſt be reckoned for a *farm* of a hundred pounds a year, or elſe the farmer will be ruined: if it be not very improveable land.

By ſtatute no parſon or ſpiritual perſon ſhall take *farms* or leaſes of land, on pain of forfeiting 10*l.* per month, &c. 21 Hen. VIII. cap. 13. And no perſon whatſoever ſhall take above two *farms* together in the ſame pariſh, under the forfeiture of three ſhillings and four-pence a week. 25 Hen. VIII. cap. 13. 32 Hen. VIII. cap. 28.

We alſo ſay, to *farm* duties, impoſts, &c.

FARMER, he that tenants a farm, or is leſſee thereof.

Alſo generally every leſſee for life, years, or at will, is called *farmer*.

As this word implies no myſtery, except it be that of huſbandry, huſbandman is the proper addition for a *farmer*.

FARMER, in *Mining*, is the lord of the field, or one that *farms* the lot and cope of the king.

FARNIA, or FARNIA *Italorum*, a name by which ſome authors have called the baſtard oak; the *cerrus*, *aegilops*, *turkey*, or other writers.

FARNOVIANS, in *Eccleſiaſtical Hiſtory*, a ſect of *Socinians*, ſo called from Stanislaus Farnovius, who ſeparated from the other Unitarians in the year 1568, and was followed by ſeveral perſons eminent for their learning. This ſect did not laſt long, for having loſt their chief, who died in 1625, it was ſcattered abroad and reduced to nothing. Farnovius was engaged by Geneſius to prefer the Arian ſyſtem to that of the Socinians, and conſequently aſſerted, that Chriſt had been produced out of nothing by the Supreme Being before the creation of this terreſtrial globe. His ſentiments concerning the Holy Ghoſt are not certainly known; however, it appears that he warned his diſciples againſt paying the tribute of religious worſhip to the Divine Spirit.

FARRA, in *Botanology*, a name given by authors to a ſpecies of the *triticum*, not differing eſſentially from the *lolium* or *zizania*. This ſpecies has had a great number of different names, and been deſcribed as five or ſix different ſorts. But all the deſcriptions of the ſeveral authors agree to prove it to be that ſpecies only of the *triticum*, which Artedi has diſtinguiſhed by the name of the *triticum*, with the upper jaw longer and flat, and with fourteen rays in the bractæ. This name equally agrees with the ſeveral deſcriptions of the *farra* or *ferra*, *bromos*, *lolium*, &c. and they agree in all the eſſential characters with one another. See TRITICUM.

FARREATION, FARREATIO, in *Antiquity*, the ſame with CONFARREATION.

FARRIER, a perſon whoſe office is to ſhoe horſes, and cure them when diſeaſed or lame.

FARRIER's *pincers*, in the *Manege*, a leathern bag, in which they carry drivets, nippers, ſhoes for all ſizes of feet, good ſharp nails, and all that is proper for new-ſhoeing a horſe that has loſt his ſhoe upon a road.

FARTHEL, or FARTHELLUS, among *Saxons*, was uſed for the ſame with what they commonly call *fuel*, or *furling*, which is taking up the ſails, and binding them cloſe to the yards.

FARTHING, a ſmall Engliſh copper coin, amounting to one-fourth of a penny.

It was anciently called *fourthing*, as being the fourth of the integer or penny.

FARTHING *of gold*, a coin uſed in ancient times, containing in value the fourth part of a noble, or 20*d.* ſilver, and in weight the ſixth part of an ounce of gold. It is mentioned in the ſtat. 9 Hen. V. cap. 7. where it is enacted, that there ſhall be good and juſt weight of the noble, half-noble, *and farthing of gold*.

FARTHING *of land* ſeems to differ from FARDING-*deal*.

For in a ſurvey-book of the manor of Weſt-Hapton in Devonſhire, there is an entry thus: A. B. holds ſix *farthings of land* at 12*d. per ann.* Blount. So that the *farthing of land* muſt have been a conſiderable quantity, far more than a rood.

FARUNDEL, *of land*, the ſame with FARDING-*deal*.

FASCE, *Faſcia*, in *Heraldry*. See FESSE.

FASCES, in *Antiquity*, rods tied up together with rods or ſtaves, and borne before the Roman magiſtrates as a badge of their office and authority.

Pliny, lib. I. cap. 5. aſſures us, that the uſe of *faſces* was introduced by the elder Tarquin, the fifth king of Rome, and that they were then the mark of the foreſaid dignity. In after-times they were borne before the conſuls, but by turns only, each his day; *ut, ſi unus faſces habuerit, duplicatus terror videretur*. Livy, lib. ii. cap. 1. They had each of them twelve, borne by ſo many uſhers, called lictors. See LICTOR. Dionyſ. Halicarn. lib. iii. cap. 84.

Others will have Romulus the author of the inſtitution, and aſcribe the number twelve to the number of birds which foretold him his kingdom. Others hold that he borrowed it from the Hetruſcians, and that the number twelve anſwered to the twelve nations of Hetruria, who, in creating him king, gave him each an enſign to ſerve him as lictor. Silius Italicus aſcribes the firſt invention to a city of Hetruria, called Veſulonia.

Theſe *faſces* conſiſted of bundles of elm; in the middle whereof was a ſecuris or ax, the head whereof ſtood out beyond the reſt. Plutarch relates the reaſon of this diſpoſition. Publicola took the ax out of the *faſces*, as Plutarch aſſures us, to remove from the people all occaſion of terror. After the conſuls the prætors aſſumed the *faſces*. Cenſorin. De Die Natal. obſerves, that the prætors had only two, though Polybius and Plutarch give them ſix.

In the government of the decemviri it was the practice at firſt for only one of them to have the *faſces*; afterwards each of them had twelve, in the ſame manner as the kings.

In funeral proceſſions it was the cuſtom to carry the *faſces* reverſed, as a token of grief.

FASCES, in *Gunnery*, the irons thruſt into the mouths of the bottles when made to remove them into the ſmelting-tower.

FASCIA, in *Architecture*, by the workmen called FACIA, FACIE, or FACE, a broad flat, fillet, or band, particularly uſed in architraves and peſtaſtals.

The architrave conſiſts of three *faſciæ* or bands; thus called by Vitruvius, as reſembling ſwaths, called in Latin *faſciæ*.

That author admits of no *faſcia* in the Tuſcan and Doric architrave; i. e. he makes it all plain, without any diviſion or cantoning into parts or *faſciæ*; but the modern architect takes the liberty to differ from him in this particular. See *Tab. Archit. fig.* 25. N° 25.

In brick-buildings, the jutting out of the bricks beyond the windows in the ſeveral ſtories, except the loweſt, are called *faſciæ* or *faſcie*.

Theſe are ſometimes plain, and ſometimes moulded; but the moulding is only a *cima reverſa*, or an ogee, at the bottom, with two plain courſes of bricks over it; then an aſtragal, and laſtly a boulting.

FASCIA *lata*, in *Anatomy*, a large membranous, tendinous, or ligamentary covering, very conſiderable both for its extent and ſtrength, being made up chiefly of two planes of fibres, of which the external are more or leſs longitudinal, the internal more or leſs tranſverſe. It is farther ſtrengthened in ſome places by a great number of other fibres, which augment its thickneſs, and form particular expanſions. The tranſverſe fibres are much ſtronger than the longitudinal. It is fixed above to the edge of the criſta of the os ilium from the large tuberoſity to the anterior ſuperior ſpine, to the ligamentum Fallopii, and to the aponeuroſis of the obliquus externus of the abdomen, on which it runs up by a thin lamina. It is likewiſe fixed in the lateral inferior part of the os ſacrum, and to the neighbouring parts of the ligaments, by

which that bone is connected to the os ilium and ischium, from whence it passes over the gluteï and thigh, between the membrana adiposa and muscles, all the way to the anterior and outer parts of the knee. It is very thin on the patella, but may be separated from it. It is also continued over the external anterior part of the tibia, covering the muscles which lie there, and is strongly inserted in the head of that bone, and in the upper part of the fibula. It sends off ligamentous, which, like so many septa, run in between the muscles, and sometimes meet in such a manner as to form vaginæ. It is strongest on the anterior and outer parts of the thigh, growing gradually thinner on the inner and back parts. It is strongly inserted in the linea femoris aspera, between the vastus externus and biceps, forming a sort of septum between these muscles. It furnishes particular vaginæ to the muscles which lie on the inside of the thigh; and though these vaginæ are thin, they are pretty strong, being chiefly made up of transverse fibres. The *fascia lata* more or less surrounds all the muscles that serve to move the os femoris on the pelvis, and also the pelvis on the os femoris. This name has been sometimes erroneously given to a small anterior superficial muscle, more properly called *musculus fasciæ latæ, or musculus* MEMBRANOSUS. Winslow's Anatomy, p. 204.

FASCIA, in *Surgery*, is a fillet, roller, or bandage. It is extremely difficult to form an idea of bandages without seeing them made. See BANDAGE.

FASCIÆ, in *Astronomy*, two rows of bright spots observed on Jupiter's body, appearing like swathes or belts.

The *fasciæ*, or belts of Jupiter, are more lucid than the rest of the disk, and are terminated by parallel lines. They are sometimes broader, and sometimes narrower; nor do they always possess the same part of the disk.

M. Huygens likewise observed a very large kind of *fascia* in Mars; but it was darker than the rest of the disk, and took up the middle part thereof. See BELTS.

FASCIALIS, in *Anatomy*, a muscle of the leg, called also SARTORIUS.

FASCIATION, in *Surgery*, is the binding of swathes about a limb that is to be cured.

FASCICULATA *Folia*, among *Botanists*. See LEAF.

FASCICULUS, in *Medicine*, a term sometimes used to express a certain quantity or measure of herbs.

Bi fasciculus is meant so much as may be held in the arm when bent, and rested on the top of the hip. Physicians note it in prescription by *fasc.*

FASCINATION denotes a sort of WITCHCRAFT, supposed to operate by the influence either of the eye or the tongue.

The word is formed from the Greek, βασκανία, which signifies the same.

Ancient writers distinguish two sorts of *fascination*, one performed by looking, or the efficacy of the eye. Such is that spoken of by Virgil in his third eclogue:

Nescio quis teneros oculus mihi fascinat agnos.

The second by words, and especially malignant praises. Such is that mentioned by the same poet in the seventh eclogue:

Aut, si ultra placitum laudarit, baccare frontem
Cingite, ne vati noceat mala lingua futuro.

Horace touches on both kinds in his first book of epistles:

Non iste obliqua oculo mea commoda quisquam
Limat, non aliis inficiet, morsuque venenat.

FASCINES, in *Fortification*, *faggots*, are small branches of trees, or bavins, bound up in bundles, which, being mixed with earth, serve to fill up ditches, to screen the men, make the parapets of trenches, &c. See *Tab. Fortif. fig.* 4.

Some of them are dipped in melted pitch or tar; and, being set on fire, serve to burn the enemy's lodgments, or other works.

A pitched *fascines* is about a foot and a half, or two feet long. Those that are used for making epaulements or chandeliers to raise works or fill up ditches are 10 feet long, and 1 or 11 foot in diameter. They are formed by fixing six small pickets in the ground by pairs, so as to make little trestles, and well fastened in the middle with willow bindings. On these trestles the branches are laid, which are bound round with withes at the distance of every two feet.

In the corrupt Latin they use *fascinina*, *fascennia*, and *fascinata*, to signify the pales, *fascines*, &c. used to inclose the ancient castles, &c.

FASHION. The word is French, *façon*, which signifies *making*.

FASHION is particularly used among *Artificers* for the trouble, time, and labour, employed in a piece of work, particularly of silver or gold.

It is by the *fashion* that the workmen's wages or salary is regulated.

The word is also used to denote the prevailing mode or style.

FASHIONS, a name sometimes given to the FARCIN.

Fashion-pieces, in the *Sea-language*, two pieces of timber which form the breadth of a ship at the sterns, and are the outmost timbers of the STERN on each side, forming its shape, and united to the stern-post and to the extremity of the wing-transom by a rabbit, and a number of strong nails or spikes driven from without.

FASSETS, among *Jewellers*. See FACETS.

FASSUS, in our *Old Writers*, is used for a faggot of wood. It seems to come from the French, *fassiau*.

FAST, a space of time wherein a person takes little or no food.

For the advantages of *fasting* with regard to health, see ABSTINENCE.

The Bramins never bleed their sick, but make them *fast*.

FAST is peculiarly used for an abstinence on account of religion, or a space of time wherein the church prohibits the use of food, or at least restrains it to certain kinds, and to certain hours.

Fasting has been practised by most nations from the remotest antiquity.

The Jews observed *fasts* from their first establishment. Moses appointed one solemn *fast* before the feast of expiation; and others were instituted by the following prophets on different occasions; so that in the time of Zechariah there were four regular *fasts*, viz. in the months June, July, September, and December. To these they have since added three others, in memory of their calamities they have at different times suffered. Besides these, there are various kinds of *fasts*, some for [illegible] others for the new moons; and some [illegible] an anniversary *fast*, in [illegible] the Septuagint, in order [illegible] their doctors for a [illegible] ed to the dignity of [illegible] ocus opinon, was only designed for the multitude: *Non fecit rabbi omnes matres.*

There is no occasion to describe exactly the various observances that accompanied these acts of humiliation, as being generally known. Their abstinence lasted twenty-seven or twenty-eight hours, beginning before sun-set, and not ending till some time after sun-set the next day. On these days they were obliged to wear white robes, in token of their grief and repentance; to cover themselves with sackcloth, to lie on ashes, to sprinkle them on their head, and on great occasions cover the ark of the covenant. In order to complete their abstinence, they eat nothing at night but a little bread steeped in water, seasoned with salt, or bitter herbs and pulse. Some of them continued the following day and night praying in the temple or synagogue, bare-footed, and occasionally scourging themselves.

Those that would be particularly informed of these austerities may consult Maimonides, Leo of Modena, and Buxtorf.

The Egyptians, Phœnicians, and Assyrians, neighbours to the Jews, had also their *fasts*. The *fast* of the Ninivites, occasioned by the preaching of the prophet Jonas, is too well known to be instilled on.

Nor were the Greeks without their *fasts*. Aristotle informs us, that the Lacedæmonians having resolved to succour a city of the allies, ordained a general *fast* through the whole extent of their dominions, without excepting the domestic animals; and this they did for two ends, one that they might spare provision in favour of the besieged, and the other to draw the blessing of heaven on their enterprize. The Athenians, among others, had the Eleusinian and Thesmophorian *fasts*, the observation of which was accompanied with strict *fasting*, particularly among the women, who spent one whole day sitting on the ground in a mournful dress, without taking any nourishment; on which account this day was called ATERUS.

In a word, all the Pagan deities, whether of the male or female sex, required this duty of those that desired to be initiated into their mysteries, of their priests and priestesses that gave the oracles, and of those that came to consult them.

In Italy *fasting* was observed much in the same way. The inhabitants of Tarentum, being besieged by the Romans, demanded succours from their neighbours of Rhegium, who immediately ordained a *fast* throughout their whole territories, with the same intention as the Lacedæmonians, viz. to render the gods favourable, and to spare provisions for their allies. Their enterprize having had good success by their throwing a convoy with provisions into the town, the Romans were obliged to raise the siege: and the Tarentines, in memory of this deliverance,

livery, instituted a perennial *fast*. So that here we have two *fasts* for the same event; that observed by those who were the means of obtaining the deliverance, and that observed by them who received it. The Roman senate, Livy tells us, being alarmed by many prodigies happening in a train one after another, ordered the decemviri to consult the Sibylline books; who having executed his commission, declared, that to prevent the fatal consequences, it was necessary to establish a *fast* in honour of Ceres, to be observed every fifth year. That Jupiter had stated *fasts* at Rome, appears from the following passage of Horace, where a mother is introduced praying to Jupiter for the recovery of her son from a quartan ague, and promising that the patient should purify himself in the Tiber on the morning of the *festi-day* sacred to that god:

Frigida si puerum quartana reliquerit, illi
Mane die quo tu indicis ieiunia, nudus
In Tiberi stabit.

Fasting must have been very sacred at Rome, since we find it practised by kings and emperors. Numa Pompilius, Julius Cæsar, Augustus, Vespasian, and others, we are told, had their stated *festi-days*; and Julian the Apostate was so exact in this observance as even to outdo the priests themselves, and the most rigid philosophers.

In a word, every country, nation, and religion, have had at all times their priests, druids, gymnosophists, and philosophers, who distinguished themselves by their frugality, austerity, and abstinence. The practice of the Pythagoreans is well known; their whole life was a continued lent, but with this difference between them and us, that they believed the use of fish equally unlawful with that of flesh. They lived entirely on bread, fruits, and pulse, with great sobriety, in imitation of their master Pythagoras; though in this respect they must have fallen far short of him, if we may believe Diogenes Laertius, who says that he continued his *fasts* for no less than forty days. Apollonius Thyaneus, one of his most famous disciples, could never by all his endeavours equal his master in this point, though his *fasts* greatly exceeded the ordinary intervals.

The gymnosophists or brachmans reckoned *fasting* among their religious duties. Father Le Compte, in his Memoirs, tells us, that the Chinese have at all times had regular *fasts*, with forms of prayer, for preserving them from barrenness, inundations, earthquakes, and such like public calamities. The Mahometans too, who possess so large a part of Asia and Africa, have times of *fasting*, called by them *ramadan*, as regular as we have lent: and their dervises are remarkable for their mortification and *fasting*. Compte, Mem. tom. ii. p. 142.

The Turks are so scrupulous on the point of *fasting*, that they will not at those times so much as take the smell of any perfume by the nose. They hold that odours themselves break *fast*. If they bathe, it is forbid to put the head under water for fear of swallowing any of it; and as for women, they are forbid to bathe at all on *fast days*, for a reason peculiar to the sex.

It was not unusual among the ancients to *fast* on account of dreams.

Mr. Bayle observes, that whole books have been written on long *fasting*. Cyriacus Lentulus has compiled one, De Prodigiosis Inediis. Fortunius Licetus, professor of medicine at Padua, besides a great many others, has published one book in folio, De iis qui diu vivunt sine Alimento, or De Fetiis Altricis Animæ.

Though *fasting* is not positively enjoined by Christ or his apostles, a custom prevailed among the first Christians of joining abstinence with their prayers, especially when they were engaged in affairs of extraordinary importance. But in the most ancient times we find no mention of any public and solemn *fasts*, except upon the anniversary of Christ's crucifixion. However, in process of time, days of *fasting* were gradually introduced, first by custom, and afterwards by positive appointment; though it is not certain what those days were, nor whether they were observed in the first century. Mr. Mosheim acknowledges, that those who affirm, that in the time of the apostles or soon after, the fourth and sixth days of the week were observed as *fasts*, are not destitute of specious arguments in favour of their opinion. Eccles. Hist. vol. i. p. 106. 8vo.

Towards the close of the third century *fasting* was held in much greater esteem, from a notion that it served as a security against the power of demons, who directed their stratagems principally against the luxurious. About the end of the fourth century this notion still more generally prevailed; and *fasting* was also considered as the most effectual means of appeasing the anger of an offended deity. Hence proceeded the establishment of this practice as an indispensable duty, by express laws enacted by the rulers of the church. The Quadragesimal or Lent *fast* was held more sacred than all the rest, though it was not yet confined to a certain number of days. But as *fasting* became more general, it was contrived to render it more easy; and therefore a mere abstinence from flesh and wine was judged sufficient; which opinion prevailed from this time, and became universal among the Latins. Ib. vol. i. p. 237. 314.

The third canonical *fast* only allows of one meal in twenty-four hours. F. Thomassin observes that the ancient *fast* was to sup without dining; i. e. only to take one meal, and that not till after noon: adding, that to dine without supping, was a breach of the *fast*. The practice of the Latin church was to *fast* thirty-six days in the year; which is, as it were, the tithe of the year.

Tertullian wrote an express treatise De Jejuniis, of *fasts*, to support the new laws of *fasting*, which the Montanists were for imposing.

The ancient catholics allowed of no obligatory or commanded *fasts* besides that preceding Easter, since called *Lent*; the terms of which were to forbear eating till the evening.

The other *fasts* observed were only of devotion; such were the fourth and sixth ferie; i. e. Wednesdays and Fridays.

This Lent *fast* was called *station*. Besides these, there were occasional *fasts* enjoined by the bishops, &c. See ABSTINENCE and LENT.

Some introduced the æsophagy into *fasts*; that is, the use of dried fruits for their meals; and made a practice of abstaining not only from all meats and wines, but also from succulent fruits, for the whole twenty-four hours; and some reduced themselves to bread and water: but this was more than was commanded.

FAST-*days* are those appointed by public authority to be observed by *fasting* and humiliation. See ABSTINENCE.

FAST-*ground*, or FAST-*country*, a term used by some of our *Miners* to express what others call the SHELF.

FASTERMANS, or FASTING-MEN, q. d. *homines jejunantes*, was used in our ancient customs for men in repute and substance; or rather for pledges, sureties, or bondsmen, who, according to the Saxon policy, were *fasting* bound to answer for one another's peaceable behaviour.

FASTI, in *Antiquity*, the Roman CALENDAR; wherein the several days of the year, with their feasts, games, and other ceremonies were expressed.

The Romans had their *greater* and *lesser fasti*. The *great fasti* were called the *fasti* of the magistrates; and the *lesser*, the *fasti calendares*.

The *fasti calendares*, which were what was properly and primarily called *fasti*, are defined by Festus Pompeius to be books containing a description of the whole year; i. e. ephemerides, or diaries, distinguishing the several kinds of days, FESTI, PROFESTI, FASTI, NEFASTI, &c. The author hereof was Numa, who committed the care and direction of the *fasti* to the *pontifex maximus*, whom the people used to go and consult on every occasion. This custom held till the year of Rome 450, when C. Flavius, secretary to the pontifices, exposed in the *forum* a list of all the days wherein it was lawful to work; which was so acceptable to the people, that they made him curule ædile. Liv. lib. ix. cap. 46. Ed. Crevier. tom. i. p. 573.

These *lesser fasti*, or *fasti calendares*, were of two kinds, *urbani* and *rustici*. The *fasti urbani*, or *fasti* of the city, were those which obtained, or were observed in the city. Some will have them thus called because they were exposed publicly in divers parts of the city; though by the various inscriptions or gravings thereof on antique stones, one would imagine that private persons had them likewise in their houses. Ovid undertook to illustrate these *fasti urbani*, and comment on them in his Libri Fastorum, whereof we have the six first books still remaining; the six last, if ever they were written, being lost. Beside Ovid, several other authors had undertaken the same subject, particularly L. Cincius Alimentarius, Fulvius Nobilior, Maturius Sabinus, Cornelius Labeo, C. Licinianus, and Nisus; of all whom Macrobius makes mention in his Saturn, and preserves fragments of each; besides a work of one Babius Marcus, intituled, De Fastis Diebus, quoted by Fulgentius, De Prisco Sermone.

In the *greater fasti*, or *fasti* of the magistrates, were expressed the several feasts, with every thing relating to the gods, religion, and the magistrates; the emperors, their birthdays, offices, days consecrated to them, and feasts and ceremonies established in their honour, or for their prosperity, &c.

With a number of such circumstances did flattery at length swell the *fasti*, when they became denominated *magni*, to distinguish them from the bare calendar, or *fasti calendares*.

In the *fasti rustici*, or *country fasti*, were expressed the several

several days, festæ, &c. to be observed by the country people; for as these were taken up in tilling the ground, fewer feasts, sacrifices, ceremonies, and holidays, were enjoined them than the inhabitants of cities; and they had also some peculiar ones not observed at Rome.

These rustic *fasti* contained little more than the ceremonies of the calends, nones, and ides; the stars, signs of the zodiac, increase and decrease of the days, the tutelary gods of each month, and certain directions for rural works to be performed each month.

FASTI was also a chronicle or register of time, wherein the several years were denoted by the respective consuls, with the principal events that happened during their consulates; these were called also *fasti consulares*, or *consulum fasti*.

Onuphrius Panvinius, Pighius, Sigonius, and Janssen d'Almeloveen, have given us the *fasti consulares*; the two first, with long and learned comments, wherein are expressed not only the consuls, but also the dictators, magistri equitum, triumphs, and ovations. Pighius even adds as many of the other officers as he could find, viz. praetors, tribunes, &c. J. d'Almeloveen confines himself to the consuls alone.

FASTI is that applied to the archives and public records wherein are kept historical memoirs of public and remarkable events that have happened to a people.

In the like sense the martyrology is called the *sacred fasti* of the church.

The Jesuit Du-Londel has compiled the *fasti* of Louis le Grand, &c.

FASTI, or *dies fasti*, also denoted court days. See DAY.

The word *fasti*, *fasterum*, is formed of the verb *fari*, *to speak*, because during those days the courts were open, causes might be heard, and the prætor was allowed *fari*, to pronounce the three words, *a*, *dico*, *addico*; the other days wherein this was prohibited were called *nefasti*: thus Ovid,

Lex nefastus erit, per quem tria verba silenter
Fallus erit, per quem lege licebit agi.

These days *fasti* were noted in the calendar by the letter *F*; but observe, that these were some days *ex parte fasti*, partly *fasti*, partly *nefasti*; i. e. justice might be distributed at certain times of the day, and not at others. Those days were called *intercisi*; they were marked in the calendar thus, *F. P. fastus prorsus*, where justice might be demanded during the first part of that day.

FASTIDIUM *Cibi*. See NAUSEA.

FASTIGIATI *Fumi*, in *Chemistry*, fumacres fitted with several alembics.

FASTIGIUM, in *Architecture*, the same with PEDIMENT.

FASTING *Man*. See FASTERMANS.

FAT, in an *Animal Body*, a white, oily, concrete substance, collected in little membranous loculi or cells in divers parts of the body, serving to keep the parts warm, to soften and temper the acids of the aliments in the mass of blood, and probably for the nourishment and reparation of the human body. It is well known that animals become lean and live upon their *fat* when they have too little food; and when they have diseases which prevent digestion and production of the nutritive juice; in which case the *fat* appears to be absorbed by the vessels designed for this use, and to be transformed into nutritive juice: it is also a fact, that the *fattest* persons falling into an atrophy, gradually lose all their *fat*, which is always quite expended in such cases before the disease becomes fatal. See ADIPS.

The vapours which rise from *fat*, either heated in the open air, or distilled in close vessels, consist of acid and attenuated oil: the acid is extremely penetrating, acrid, and volatile; it irritates and inflames the eyes, throat, and lungs; and excites a cough as much as volatile sulphureous acid does, though its nature be very different; and yet in this natural state this acid is so well combined with the oily part, that none of its properties can be perceived. *Tal*, though very mild in good condition, becomes irritating and caustic when its acid is partly disengaged by fire or time. Spirit of wine, which does not affect pure and unchanged *fat*, dissolves some portion of *fat* which has been strongly heated, or which has become rancid; whence it is inferred, that the acid of the *fat* disengages itself in both these cases.

This *fat* found immediately under the cutis, inclosed in little bags, called *cellulæ adiposæ*, adhering to the outer surface of the membrane, called *adipose*, all over the body, except on the forehead, eye-lids, penis, and testicles, is nothing but the oily part of the aliment or chyle which could not enter into the composition of the nutritive juices, transmitted from the arterial blood by the adipous glands, and carried by peculiar ducts to the membranous cells, whence it is transmitted again to the blood by the veins. Dr. Grew takes it to be a *coagulum* of the oily parts of the blood, made either by some of its own saline parts, or by the nitrous particles of the air mingled therewith in the lungs; which sentiment is confirmed by an experiment of that learned person, who made an artificial *fat*, by only mixing oil of olives with spirit of nitre for some days: and hence it is that divers animals, as rabbits, hares, &c. grow *fat* in winter, and particularly in severe frosty weather, these then abounding most in nitre. Hence also it is that the *fat* of land animals is much firmer than that of fishes, the watery element containing less nitrous matter than the air.

In some subjects the cellulæ are so full and distended that the *fat* is above an inch thick; in others they are almost flat; and in emaciated subjects, instead of *fat*, we find a sort of flaccid transparent substance, which is nothing but the bare membrane, the cells being all exhausted.

Too much *fat* is usually attended with heaviness and drowsiness, not only from the unwieldiness of an overgrown body, but from the stuffing of the cavities and thorax alone, which sometimes obstructs the expansion of the diaphragm and lungs, and produces a dyspnœa, or an orthopnœa; and it is likewise probable that the abundance of *fatty* or oily particles returned into the blood, and impleating the more subtle and active parts, may hinder the necessary secretions of the brain. See CORPULENCY.

Mr. Hunauld has the following observations on the *fat* of the body: 1. That though fœtuses and children have much *fat* under the skin, yet they have only a small piece or two (*pelotons*) at the base of the heart; whereas in adult bodies have *fat* all round the base on the vessels that go out of the heart, and accompanying the larger coronary vessels, and at the point of the heart. 2. That the omentum of very young children has no *fat*, and their mesentery very little. 3. That [illegible] *fat* under the skin is exhausted [illegible] overcharged with [illegible] cellulæ in the full adult [illegible] of it; from which, and [illegible] and membranes spread over so many [illegible], he concludes, the common opinion of muscles being lubricated by the *fat*, to be ill founded. See Mem. Acad. Scienc. 1732.

The *fat* of different animals has been represented by some writers as of considerable medicinal use: thus, *Cabrit fat* is used in pomatums and unguents, being resolutive and emollient. That of *bears* and *boars* has the same qualities, and is also strengthening. *Deers grease* is accounted good to fortify the nerves against the rheumatism, sciatica, gout, and fractures. *Hares grease*, applied externally, promotes digestion, and a suppuration of abscesses. That of *wolves* is nervous and resolutive, That of *ducks* and *hens*, resolves and softens indurations. That of *geese* has the same qualities; and likewise abateth haemorrhoids, allayes pains in the ear, being applied within the same; and opens the belly, being taken inwardly. *Eels fat* is esteemed good against the haemorrhoids and deafness, to take away pits of the small-pox, and to make the hair grow. That of the *trout*, besides its being emollient, is said to be good in diseases of the anus, and in ulcers of the breast.

But the specific virtues ascribed to certain *fats* do not seem well warranted; some even doubt their being possessed of any properties different from other sublstances of like kind, unless what may arise out of their different consistencies and degrees of volatility; that of the viper seems to have the smell right to claim something extraordinary upon that account. See ADIPS.

The way of preparing *fat* for medicinal purposes is to take out the *fibres*, veins, fibres, &c. wash it till it becomes unbloody; then melt it by a gentle heat, with a little water, till the water is evaporated; strain, put it into an earthen vessel where it will fix, and preserve it from air.

Fat of whales. See BLUBBER.

FAT, or VAT, is a kind of vessel used for holding wine, ale, beer, cyder, or any other liquor, in the time of its preparation.

FAT, or *vat*, also expresses a large wooden vessel, which, among brewers and maltsters, is used to measure MALT for expedition, containing a quarter or eight bushels, stat. 1 Hen. V. cap. 10. and 11 Hen. VI. cap. 8.

FAT is likewise a vessel or pan of lead, used in making salt, &c. See SALT.

FAT also denotes an uncertain measure of capacity: thus, a *fat* of shingles contains from 3½ hundred weight to 4 hundred weight; a *fat* of unbound books half a maund, or 4 bales; of wire, from 20 to 25 hundred weight; and of yarn, from 220 to 221 bundles.

FATE, FATUM, in a general sense, denotes an inevitable necessity depending on some superior cause.

Fatals a term much used among the ancient philosophers.

It is formed *a fando, from speaking*, and primarily implies the same with *effatum*, viz. a word or decree pronounced by God; or a fixed sentence, whereby the Deity has prescribed the order of things, and allotted every person what shall befal him.

The Greeks call it εἱμαρμένη, *from* εἶρος *nexus, a chain*, or necessary series of things indissolubly linked together.

All things, says Plato, are in *fate*; i. e. within its sphere or scheme, but all things are not *fated*; and he thus explains the distinction: it is not in *fate*, says he, that one man shall *do* so and so, and another *suffer* so and so, for that would be destructive of our free agency and liberty; but if any one should choose such a life, or do such or such things, then it is in *fate* that such things and such consequences shall ensue upon it. The soul, therefore, is αὐτεξούσιον, free and uncontrolled, and it lies within itself to act or not; and there is no compulsion or necessity here; but what follows upon the action shall be accomplished, κατ' ἀναγκαστον, according to *fate*, or the constitution of things; e. gr. that Paris should bear off Helen by force was something dependent on himself; but that a war should ensue is the consequence. Ex Alcinoo de Platon. Dogmat.

The same philosopher, as cited by Hierocles, observes to this purpose: the choice of action is in our own power; but the just award or retribution of good or ill which ensues upon the choice, lies in the breast of those etherial judges who are appointed under God.

But beside this sense of the word wherein it is used, sometimes to denote the connection of causes in nature, and sometimes in the divine appointment, the word *fate* has a farther intention, being used to express a certain necessity or external designation of things, whereby all agents, both necessary and voluntary, are swayed and directed to their ends. See NECESSITY.

Some authors divide *fate* into *astrological* and *physical*.

FATE, *astrological*, denotes a necessity of things and events, arising, as is supposed, from the influence and positions of the heavenly bodies, which give law both to the elements and mixed bodies, and to the wills of men.

In which sense the word is often used by Manilius, *Certum est & inevitabile fatum: materiaque datum est cogi, sed cogere stellis.*

FATE, *physical*, or *fatality*, is defined by Cicero an order or series of causes, wherein cause being linked to cause, each produces the other; and thus all things flow from one prime cause. Chrysippus defines it a natural invariable succession of all things *ab æterno*, each involving the other.

To this *fate* they subject the very gods. Thus the poet: the Parent of all things made laws at the beginning, by which he not only binds other things, but himself. So Seneca: *Eadem necessitas & deos alligat. Irrevocabilis divina portat & humana cursus vehit. Ipse ille omnium conditor & rector scripsit quidem fata, sed sequitur: semel scripsit, semper paret.*

This eternal series of causes the poets call Μοῖρα and Parcæ, or *Destinies*.

Fate is divided by some later authors into *physical* and *divine*.

FATE, *physical*, is an order and series of natural causes appropriated to their effects.

This series is necessary, and the necessity is natural. The principle or foundation of this *fate* is nature, or the power and manner of acting which God originally gave to the several bodies, elements, mixts, &c. By this *fate* it is that fire warms, bodies communicate motion to each other, the sun and moon occasion the tides, &c. and the effects of this *fate* are all the events and *phænomena* in the universe, except such as arise from the human will. See NATURE.

FATE, *Divine*, is what we more usually call PROVIDENCE. Plato in his Phædo includes both these in one definition, as intimating, that they were one and the same thing, actively and passively considered. Thus, Fatum *est ratio quædam divina, lesque naturæ certæ, quæ transiri nequeat, quippe a causa pendens, quæ superior sit quibuslibet impedimentis.* Though that of Boethius seems the clearer and more just, Fatum, says he, *est inhærens rebus mobilibus dispositio, per quam Providentia suis quæque nectit ordinibus.*

FATHER, *Pater*, a term of relation, denothing a person who begot a child, either male or female.

Among the ancient Romans the *fathers* of three children had very considerable privileges allowed them as such. By the law of Romulus a *father* had an absolute and unlimited power over his children. Amongst the Lacedæmonians, we learn from Aristotle's Politics, the *father* of three children was excused from the duty of mounting guard for the security of the city; and a *father* of four children was exempted from every public burden.

FATHER, *adoptive*, is he who takes the children of some other, and acknowleges them as his own. See ADOPTION.

FATHER, *putative*, is he who is only the reputed or supposed *father*. Joseph was *putative father* of our Saviour.

FATHER, *natural*, is he who has illegitimate children.

FATHER-*in-law*, is a person married to a woman who has children by a former husband, &c. to which children he is said to be a *father-in-law*.

FATHER is also used in *Theology* for the first person in the TRINITY.

FATHER is also used in a figurative sense on divers moral and spiritual occasions. Thus, it is applied to the patriarchs; as we say Adam was the *father* of all mankind, Abraham the *father* of the faithful, &c.

FATHERS, in an *Ecclesiastical Sense*, denote the ancient prelates and doctors of the church.

The *fathers* assembled at the council of Nice; Chrysostom, St. Basil, &c. were Greek *fathers*, and St. Augustine, St. Ambrose, &c. were Latin *fathers*.

The appellation of *fathers* is usually confined to the theological writers of the first six centuries.

FATHERS, *apostolical*. See APOSTOLICAL.

FATHERS is also a title of honour given to prelates and dignitaries of the church. The right reverend *father* in God, lord bishop of, &c. *ab curæ similitudine* patres *appellantur*.

FATHER is also applied to the superiors of Convents, &c. See ABBOT. The *father* general; father provincial, ex-provincial; *father* prior, sub prior; *father* definitor, in the order of Benedictines; *father* guardian, in that of the Franciscans; *father* corrector, among the Minims, &c.

FATHERS is also applied plurally to all congregations of ecclesiastics, whether regular or secular; as the *fathers* Cordeliers, Capuchins, Augustins, Jacobins, &c. The *fathers* Jesuits, *fathers* of the Oratory, Barnabites, Theatins of the Mission, &c. See each under the proper article.

FATHERS *of the Christian doctrine* is a denomination belonging to two religious orders: one instituted in France by Cæsar de Bus, and confirmed in 1597, by Clement VIII. and another in Italy founded by Colani, a Milanese knight, and established by the authority of Pius V. and Gregory XIII.

FATHERS *of Somasque, or regular clerks of St. Maiolus*, is the appellation of a religious order deduced from the name of the place where their founder resided. It was first formed into a distinct society by Jerome Æmiliani, a noble Venetian, and confirmed by Paul III. and Pius IV. in 1540 and 1563. Their office was the instruction of the young and ignorant, and the relief of orphans.

FATHERS is also used for persons venerable for their age or quality, or the services they have done the public.

Thus, at Rome the senators were called *conscript fathers, patres conscripti*, &c.

FATHER-*lasher* in *Ichthyology*, an English name given to a fish, called by some authors, though improperly, SCORPÆNA, and *scorpius marinus*. It is properly of the COTTUS kind, and is named by Artedi the smooth cottus without scales, with several spines upon the head, and with the upper jaw a little longer than the under. It more resembles the small fish we call the *bullhead* or *miller's thumb*, than the SCORPÆNA. The head is large and armed with spines, which it can oppose to any enemy that attacks it, by swelling out its cheeks and gill-covers to a large size. The nose and space contiguous to the eyes are furnished with short sharp spines, and the covers of the gills are terminated by very long ones, which are strong and sharp-pointed. The mouth is large; the jaws are covered with rows of very small teeth; and the roof of the mouth is furnished with a triangular spot of minute teeth. The back is more elevated than that of others of this genus; the belly prominent; the side-line rough; the rest of the body very smooth, and growing slender towards the tail. This kind is very frequent in the Newfoundland seas, where it is called *sculping*; and it is common on the coast of Greenland in deep water, near the shore. It is a principal food of the natives, and soup made of it is said to be both agreeable and wholesome. See *Tab. of Fish. fig. 4.*

FATHIMITES, or FATHEMITES, the descendants of Mahomet by Fathima, or Fathema his daughter.

The dynasty of *Fathimites*, i. e. of princes descending in a direct line from Ali and Fathima his wife, Mahomet's daughter, commenced in Africa in the year of the Hegira 296, or Jesus Christ 908.

The *Fathimites* afterwards conquered Egypt, and established themselves therein in quality of caliphs.

The *Fathimites* of Egypt ended with Aded, in the year of the Hegira 567, 268 years after their first establishment in Africa, and 208 years after the conquest of Egypt.

FATHOM, a long measure containing six feet, taken from the utmost extent of both arms when stretched into a right line.

The *fathom* is used at sea in estimating the length of cables and other ship-ropes, with the depths and soundings of the sea; as also in mines, quarries, wells, and works of fortification.

There are three kinds of *fathoms*, accommodated to the different ranks of vessels: the first, which is that of men of war, contains six feet; the *middling*, or that of merchant-ships, five feet and a half; and the *small fathom*, used in buyers, fly-boats, and other fishing-vessels, only five feet.

FATHOM is also used in several countries, particularly Italy, for the common yard or ell whereby things are ordinarily measured in commerce.

In this sense it is more commonly called *brasse*, or *brassia*, q. d. arm. In Muscovy the *fathom* contains seven English feet, and about two-tenth et an inch.

FATNESS, in *Medicine*, CORPULENCY, or the state of a person too much loaded with flesh and fat. See an account of a remarkable case of *fatness* in the Med. Obs. &c. vol. iii. p. 69, &c.

FATTENING *of Colours*, among *Painters*, denotes a coagulation of the oil, which frequently happens on its being mixed with several kinds of pigments; whence, after being kept for some time, it is rendered of so viscid or glutinous a consistency as to be wholly incapable of being worked with either brush or pencil. This also happens sometimes after the colours, have been spread or laid on the proper ground; in which case one part of the oil will run off in small streams or drops, while the other will remain with the colours without shewing the least tendency to dry. Oils likewise will *fatten* by long keeping, or by being exposed for a considerable time to the sun and air.

FATTENING *of horses*. See HORSES.

FATUARII, in *Antiquity*, were persons who, appearing inspired, foretold things to come.

The word is formed of Fatua, wife of the god Faunus, who was supposed to inspire women with the knowledge of futurity, as Faunus himself did the men. Fatua had her name from *fari*, q. d. *vaticinari*, to *prophesy*.

FATUUS *ignis*. See IGNIS *fatuus*.

FAUCON, or FALCON, a name formerly given to a small piece of cannon, whole diameter was 2¼ inches; weight 750 pounds; length, 7 feet; load, 2¼ pound; shot, 2¼ inches diameter; and 2¼ pound weight. See CANNON and GUN.

FAUCONET, or FALCONET, a very small piece of ordnance, whose diameter at the bore was 2¼ inches; weight, 400 pounds; length, 6 feet; load, 1¼ pound; shot, something more than two inches diameter, and 1¼ pound weight. See ORDNANCE and GUN.

FAVIFORMA, in *Surgery*, a term used to express certain ulcers, which, when pressed upon with the finger, emit a sanies through several small holes in the manner in which honey, on pressing the comb, issues out of the cells.

FAVILLÆ *Salis*, in *Natural History*, a name given by Vitruvius and some of the more ancient writers to the natrum or nitre of the ancients. Our chemical writers, who have been used to delight much in hard names, have applied the same phrase to express our nitre; but this is a very different salt from the other.

FAVISSA, among *Antiquaries*, a hole, pit, or vault, under-ground, wherein is kept something of great value.

The word seems formed of *fossula*, a diminutive of *fovea*, *a pit or ditch*.

The *favissæ*, according to A. Gellius and Varro, was much the same with what the ancient Greeks and Romans called θησαυροὶ, *thesauri*, and what in some of the modern churches is called *archives* and *treasury*. In the Capitol there were divers *favissæ*. They were subterraneous places, walled and vaulted, having no entrance or light but by a hole at the top, which was usually stopped up with a huge stone.

They were chiefly destined for keeping the old worn statues and other ancient moveables formerly used in the temple; for religiously did that people respect and preserve whatever was consecrated. Catullus would have lowered the floor of the Capitol, but that the *favissæ* prevented him.

Festus, however, gives us a different account of the *favissæ*. According to that author they were wells or pits of water near the temples, and for the use thereof, the same with what the Greeks called ὀμφαλὸς, navel, as being round, &c. Gellius likewise gives them the name of cisterns, as well as Festus; but it is apparently for no other reason than that they bore a resemblance to them in figure.

In effect, the two notions are pretty easily reconciled, it being certain that the treasuries of some of the ancient Greek temples were the cisterns or reservoirs of water wherein people used to wash themselves before they entered the temple.

FAUNALIA, in *Antiquity*, feasts celebrated by the Romans in honour of the god Faunus.

The deity Faunus, to whom the solemnity was devoted, and from whom it was denominated, was the same among the Romans with the Pan of the Greeks.

The *Faunalia* were held on the day of the nones of December; i. e. on the fifth day of that month. The principal sacrifice was a roe-buck; or rather, according to Horace, a kid, attended with libations of wine, and burning of incense.

It was properly a country festival, being performed in the fields and villages with peculiar joy and devotion. Horace gives us a very gay description thereof in the eighteenth ode of his third book:

——*Tener pleno cultus hedus anno:*
Large nec desunt Veneris sodali
Vina crateræ: vetus ara multo
Fumat odore.

Struvius in his Roman calendar marks the feast of Faunus on the day of the ides of February, which is the thirteenth day of that month; and the *Faunalia* he places on the fifth of the ides of December, or the ninth of that month; and in chap. ix. he shews, that there really were two *Faunalia*, the one in February, mentioned by Ovid, Fast. lib. vi. ver. 246. the other on the ninth of December, mentioned by Horace, in the place just cited.

FAUNS, FAUNI, among the ancients, were a species of demi-gods inhabiting the forests; called also *Sylvani*, *Sylvani*, and little differing from the SATYRI. They delighted more particularly in vineyards, and they generally appear as attendants of Bacchus, in the representations of Bacchanal feasts and processions. They were represented as half men, half goats, having the horns, ears, feet, and tail of a goat, a very flat nose, and the rest human.

The Roman *Fauns*, we have ob[illegible] the Greek Pan. Now, in the poe[illegible] tion made of *Fauns* and Panes [illegible] all probability, therefore, "the *F*[illegible] the PANES.

Though the *Fauns* were held for demi-gods, yet they were supposed to die after a long life. Arnobius shews that their father or chief, Faunus himself, only lived 120 years.

FAVONIUS, among the Romans, the wind which blew directly from the west.

FAVORITO, in the *Italian Music*, is an epithet given to such parts of any composition as are performed to the greatest advantage. Thus, *aria favorita* is a chorus in which are employed the best voices and instruments to sing the recitativos, play the ritornellos, &c. This is otherwise called the *little chorus*, or *chorus recitante*.

FAVOUR, in *Commerce*. See DAYS *of grace*.

FAUSSE-BRAYE, in *Fortification*, an elevation of earth, about three feet above the level ground; round the foot of the rampart on the outside, defended by a parapet about four or five fathoms distant from the upper parapet, which parts it from the berme, and the edge of the ditch; its use is for the defence of the ditch. The *fausse-braye* is the same with what is otherwise called *chemin des rondes*, and *basse enceinte*.

It is of little use where ramparts are faced with wall, because of the rubbish which the cannon beats down into it: for this reason engineers will have none before the faces of the bastions where the breach is commonly made, because the ruins falling, the *fausse-braye* makes the ascent to the breach the easier; besides, that which flies from the face often kills the soldiers placed to defend it.

For these reasons it is generally disused by modern engineers, more especially since the invention of ricochetting, which renders it extremely easy to enfilade the low works of the *fausse-braye* from one end to the other.

FAUSSE *chenille*, in *Natural History*, a term used by Mr. Reaumur and other of the French writers to express a large class of worms produced from the eggs of several species of four-winged flies. These worms have greatly the appearance of caterpillars in their general form, so that they have deceived many writers an insects into an opinion that they really were so. Their bodies are long, in the manner of the caterpillar, and they are composed of several rings or joints; the skin is of the same consistence with that of the caterpillar's; and in many species the creature is variegated with beautiful colours, disposed in the same manner as those of the smooth caterpillars usually are. Both these kinds of insects have a great number of legs, and those of two kinds some membranaceous, and others scaly. Both the worm and the caterpillar have each six of the scaly legs; but the membranaceous ones are different in number, and are alone sufficient to constitute a difference between them. The caterpillars have never more than ten of these, which, with

with the fcaly ones, make fixteen, the utmoft number of the legs of any caterpillars: but thefe worms have always at leaft twelve of the latter kind of legs, which, with the fix fcaly ones, make the whole number eighteen; and many fpecies have fourteen, fixteen, or eighteen of the membranaceous ones alone. The membranaceous legs of the worms differ alfo from thofe of the genuine caterpillars, in that they are not furnifhed with the hooks at their ends, which thofe of the latter have. The legs therefore alone give a fufficient bafis of diftinction between the caterpillar and the *fauffe chenille*, or caterpillar worm; but there is yet a more obvious diftinction between them in the fhape of their heads; and by this they may always be known from each other at firft fight. The heads of the various fpecies of caterpillars are of feveral very different fhapes; fome are fhort, others long; fome more, fome lefs flatted; and fome terminate in a fharp point, while others are diftinguifhed by a fort of fit or diviſion in the back-part. Thefe differences are found in the feveral kinds of the genuine caterpillars; but the heads of all the *fauffe chenilles* are of one fhape, and that very different from all thefe; they are round and very convex, fo that they appear a part of a fmall fphere. The mouths of thefe, and of the genuine caterpillars are wholly alike, and the ſtigmata are placed in the fame manner. The eyes, however, of the two kinds fufficiently diſtinguiſh them, the *fauffe chenille* having only two, and thofe very large and prominent, and placed on each fide of the head; whereas the caterpillar has five eyes on each fide of its head, and thofe placed in a circular direction, and too fmall to be feen without the aſſiſtance of glaſſes.

Thefe creatures differ from the common caterpillars in their manner of remaining on the leaves of a plant: the caterpillar is always extended at its full length, whether it is eating or not; but the *fauffe chenille*, though it extends its body to the full length while eating, always rolls it up into a ſpiral when at reſt, making ſeveral circular turns with it, fo that the head is at the end of the outermoſt, and the tail in the very centre of the inner one. They give themſelves various odd contortions when they are ſeizing on their food; and it is a very whimſical ſight to obſerve twenty or thirty of them in thoſe kinds which live in ſociety attacking the different portions of the ſame leaf all at once, and each giving its body ſome odd turn at the ſame time. This is a common ſight on the leaves of the oſier, a whitiſh green kind being very frequent in large companies on that tree, and often ſeen thus feeding in coveys. It is remarkable that as the caterpillar feeds indifferently on every part of the leaf, this animal uſually attacks only the edges.

The creature, when it finds the time of its change into the nymph ſtate approaching, gives it ſelf the trouble of forming a caſe in which it may paſs into that ſtate, and remain in it during the deſtined time without being ſubject to external injuries: it ſpins a web of ſilk for this purpoſe of the ſhape of a little egg. This on the outſide ſhews nothing remarkable; but when cut open, it is found to be compoſed of two different ſubſtances, at leaſt of two ſubſtances of very different workmanſhip, though the materials are the ſame in both. The outer caſe is reticulated, and formed of very ſtrong threads woven in looſe open net-work; but the inner one is formed of extremely fine threads, and thoſe wove into a cloſer ſtuff than all that the loom can come up to. The outer ſtrong and coarſe web was plainly intended for no other purpoſe but for the better defending and preſerving them from injuries; and theſe two diſtinct caſes do not any where adhere to one another but barely touch; ſo that on pulling aſunder the outer one between the fingers the inner one comes out whole. The ſtrength of this exterior ſhell is extremely neceſſary, as alſo the cloſe texture of the inner one for defending the incloſed animal in the nymph ſtate from ſeveral devouring inſects. The ants in particular are very fond of theſe nymphs, and will hunt out the caſes wherever they are to be found; and if they can eat their way though them, are ſure to make a meal of the incloſed creature.

The flies produced from theſe inſects are of that kind which have no trunks, but have a ſtrong tooth on each ſide of the head, which meeting one with the other in the middle of the mouth, are able to cut any thing to pieces that the creature has occaſion to make its way though. The firſt uſe of theſe is the cutting of a hole through the double web, in which the creature finds itſelf incloſed at its birth. All the flies of this kind have a general reſemblance one to another, and may be known to belong to the ſame family, though they are very different in colour and other obvious characters. They are never very handſome, and are all as it were ſtupid, having very little motion, and ſtanding readily at any time to be caught between the fingers. Their wings always are croſſed over the body, and form a ſort of raiſed covering over it; they are not ſmooth and even as thoſe of moſt other flies, but have prominences and cavities, and ſeem as if they had been but ill expanded at the time of the creature's hatching from the nymph ſtate. Reaumur's Hiſt. In. vol. ix. p. 133. All the females of theſe flies are oviparous, no one ſpecies producing living worms; and as theſe eggs muſt neceſſarily be lodged in cavities or niches made in the ſtalks or leaves of living plants, nature has provided this creature with two inſtruments which are deſtined for this ſole purpoſe, and which are real ſaws made in the niceſt manner, with extremely ſmall teeth. The creature has the power of uſing both theſe at once, and conſequently can make an apertuie with great eaſe that ſhall be ſufficient to lodge its eggs in. Notwithſtanding that there are many different ſpecies of flies which have this ſort of inſtrument, and ſeveral of them are extremely frequent on one of the moſt common of all our garden ſhrubs, the roſe-tree; yet no author had obſerved this elegant and wonderful inſtrument till the time of Valliſnieri, who has deſcribed and figured at length the weapons of a roſe-tree fly, produced from a falſe caterpillar of that ſhrub, with two rows of teeth, one on each ſide in the manner of the ſaw of the *ſerra piſcis*, or *ſaw-fiſh*. See Rose-*fly*.

FAVUS, in *Surgery*. See Achor and Tinea.

FAUX-BOURDON, *baſtard humble-bee*, a name given by Reaumur and other French naturaliſts to the bees uſually called by us drones, and by the common people of that nation burdons, confounding them with the common humble-bee under that name. See Drone.

FAUX PUCERON, in *Natural Hiſtory*, a name given by Reaumur and others to a genus of inſects much reſembling the *pucerons* in many things but differing in ſome material circumſtances. The two principal kinds of theſe are found on the back of the leaves of the fig-trees, and in little hollow balls at the ſummits of the branches of box, formed of the upper leaves vitiated by the bitings of theſe creatures. See Fig *inſect* and Gnus *of the box*.

To FAY, in *Ship-building*, is to fit any two pieces of wood ſo as to join cloſe together: the plank is laid *to fay* to the timbers when it bears or lies cloſe to all the timbers.

FAWN, among *Hunters*, in a buck or doe of the firſt year, or the young one of the buck's breed in its firſt year.

FEAL was anciently uſed for *faithful*; hence the tenants by knights ſervice uſed to ſwear to their lords to be *feal* and *leal*, that is, *faithful* and *loyal*.

FEALTY, an oath taken at the admittance of every tenant, to be true to his lord, while he holds his land.

Fealty is uſually mentioned as ſynonymous with homage; but it differs from it, as homage conſiſts in taking an oath when the tenant comes to his land, and is done but once, being an obligation which is permanent, and binds for ever, which *fealty* does not.

They differ alſo in the manner of the ſolemnity; for the oath of homage is taken by the tenant kneeling, but that of *fealty* is taken ſtanding, and includes ſix things, which are compriſed in the words *inviolume, tutum, utile, honeſtum, facile, poſſibile*.

Inviolume, that he do no bodily injury to the lord; *tutum*, that he do him no ſecret injury in any thing which is for his defence, as in his houſe or caſtle; *honeſtum*, that he do him no injury in his reputation; *utile*, that he do not damage him in his poſſeſſions; *facile* and *poſſibile*, that he make it eaſy and not difficult for the lord to do any good which otherwiſe he might do: all which is likewiſe compriſed in Leg. Hen. I. cap. 5.

He that holds land by this only oath of *fealty*, holds in the moſt mean manner; for all, even thoſe that have a fee, hold *per ſolem & fidelitatem*; that is, by *fealty* at the leaſt.

This *fealty* is alſo uſed in other nations, as in Lombardy and Burgundy.

Indeed, as the very firſt creation of this tenure grew from the love of the lord towards his followers, ſo did it find the tenant ſo fidelity, as appears by the whole courſe of the feuds, and the breach thereof is loſs of the fee.

Hottoman, in his Commentaries de Verbis Feudalibus, ſhews a double *fealty*; the one *general*, to be performed by every ſubject to his prince, anſwering to our oath of ALLEGIANCE; and the other *ſpecial*, required only of ſuch, as in reſpect of their fee are tied by this oath towards their lords. We read of both alſo in the Grand Cuſtomary of Normandy, &c.

Fealty ſpecial was with us performed either by freemen or villains. By 17 Ed. II. ſtat. 2. the form of this oath is appointed, and as now obſerved it is as follows: "I A. B. will be to you my lord C. true and faithful "and bear to you *fealty* and faith for the lands and te- "nements which I hold of you; and I will truly do and "perform the cuſtoms and ſervices that I ought to do to "you. So help me God." The oath is adminiſtered by the lord or his ſteward; and though it is neglected in ſome manors, yet in copy-hold manors, where courts are kept, and copy-hold eſtate granted, it is generally uſed.

every lord, of whom tenements are holden at this day, may, and ought to call upon his tenants to take this oath in his court-baron, becau'e if it be long neglected he may lose his feignory, and the profits arising from escheats and other contingencies.

Fealty is incident to all sorts of tenures, except from frank-almoign and tenancy at will.

FEAR, in *Ethics*, is the apprehension of some evil likely to befal us, attended with a desire of avoiding it. This passion has been found to leffen PERSPIRATION and urine.

FEAST, or FESTIVAL, a church solemnity, or rejoicing in honour of God or a saint.

The word is formed of the Latin, *festum*, which some derive *a feriari, to keep holiday*; others from the Greek, τεταω, *I feast or entertain*, of τεσσαρα, *fourth, fire*.

Feasts, and the ceremonies thereof, have made great part of the religion of almoft all nations and fects; witneſs thoſe of the Greeks, Romans, Hebrews, Chriſtians, and Mahometans. *Feasts* among us are either *immoveable* or *moveable*.

FEASTS, *immoveable*, are thoſe conſtantly celebrated on the ſame day of the year; the principal of theſe are Chriſtmas-day, or the Nativity; the Circumciſion, Epiphany, Candlemas, or the Purification; Lady-day, or the Annunciation, called alſo the Incarnation and Conception; All Saints, and All Souls; beſides the days of the ſeveral apoſtles, St. Thomas, St. Paul, &c. which with us are *feaſts*, though not *feriæ*. See each *feaſt* under its proper article.

FEASTS, *moveable*, are thoſe which are not confined to the ſame day of the year. Of theſe the principal is Eaſter, which gives law to all the reſt, all of them following, and keeping their proper diſtances from it; ſuch are Palm Sunday, Good-Friday, Aſh-Wedneſday, Sexageſima, Aſcenſion-day, Pentecoſt, and Trinity-Sunday. See EASTER, SEXAGESIMA, PENTECOST, TRINITY, &c.

The four *feaſts* which our laws take ſpecial notice of are the Annunciation of the Bleſſed Virgin Mary, or Lady-day, the 25th of March; the Nativity of St. John the Baptiſt, held on the 24th of June; the *Feaſt* of St. Michael the Archangel, on the 29th of September; and that of St. Thomas the Apoſtle, on the 21ſt of December: on which quarterly days rent on leaſes is uſually reſerved to be paid, 5 and 6 Ed. VI. cap. 3. 3 Jac. I. cap. 1. 12 Car. II. cap. 30.

Beſide theſe *feaſts* which are *general*, and enjoined by the church, there are others *local* and *mentional*, enjoined by the magiſtrate, or voluntarily ſet on foot by the people; ſuch are the days of thankſgiving for delivery from wars, plagues, &c. Such alſo are the vigils or wakes in commemoration of the dedications of particular churches. See VIGIL, &c.

The prodigious increaſe of *feaſt-days* in the Chriſtian church commenced towards the cloſe of the fourth century, and was occaſioned by the diſcovery that was then made of the remains of martyrs and other holy men, for the commemoration of whom they were eſtabliſhed. Theſe, inſtead of being ſet apart for pious exerciſes, were abuſed in indolence, voluptuouſneſs, and criminal practices. Many of them were inſtituted on a pagan model, and perverted to ſimilar purpoſes.

The firſt *feaſts* among the Greeks were celebrated in ſolemn aſſemblies of the whole nation, on occaſion of their games, as the Olympic, the Pythian, the Iſthmian, and Nemean; in proceſs of time they had many others, the principal of which are enumerated in the courſe of this work. See Potter's Arch. vol. i. cap. 19, 20.

The Romans alſo had abundance of ſtated *feaſts* in honour of their deities and heroes; ſuch were the Saturnalia, Cerealia, Lupercalia, Liberalia, Neptunalia, Conſualia, Portumnalia, Vulcanalia, Palilia, Divalia, &c. See SATURNALIA, &c.

They had alſo *feaſts* inſtituted occaſionally; as Carmentalia, Quirinalia, Terminalia, Floralia, Compitalia, Lemuria, Vernalia, beſide other moveable and occaſional ones; as to give thanks to the gods for benefits received; to implore their aſſiſtance, or to appeaſe their wrath, &c. as the Paganalia, Feralia, Bacchanalia, Ambarvalia, Amburbalia, Sementantiva, and divers others, particularly denominated *feriæ*; as Sementivæ, Latinæ, &c. See each of theſe *feaſts* and *feriæ* in its proper place.

The *feaſts* were divided into days of ſacrifice, and days of banqueting and feaſting; days of games, and days of reſt, or *feriæ*.

There being but little hiſtory wrote, or at leaſt publiſhed in theſe days; one end of *feaſts* was to keep up the remembrance of paſt occurrences.

The principal *feaſts* of the Jews were the *feaſts* of trumpets, that of the expiation, of tabernacles, of the dedication, of the paſſover, of pentecoſt, and that of purification.

The modern Jews have other *feaſts* marked in their calendar of modern inſtitution. The Mahometans, beſides their weekly *feaſt*, or ſabbath, which is kept on Friday, have two ſolemn *feaſts*, the firſt of which is called the *Feaſt* of Victims, and celebrated on the tenth day of the laſt month of their year; and the ſecond called BAIRAM. The Chineſe have two ſolemn *feaſts* in the year, in memory of Confucius, beſides others of leſs note on other days of the year.

FEAST *of the dead*, is a ſolemn religious ceremony in uſe among the ſavages of America, ſome of whom thus teſtify their reſpect for the deceaſed every eight years; and others, as the Hurons and Iroquois, every ten years.

FEAST is alſo uſed for a banquet, or a ſumptuous meal, without any immediate view to religion.

The uſe of the word, in this ſenſe, ariſes hence; that a part of the ceremony of many of the ancient feſtivals, both thoſe of the Heathens and the *agapæ* of the Chriſtians was good eating; though Mr. Huet chooſes to derive the word from *feſtucare*, which, in an ancient Latin verſion of Origen's Comment on Matthew, ſignifies *to feaſt: Ut veniens ille Jeſus feſtinet cum deſiderio ſuo.*

In all antiquity, both ſacred and prophane, ſacrifices were little more than religious *feaſts*.

It has been often obſerved by authors, that there is no nation in the world comes near the Engliſh in the magnificence of their *feaſts*. Thoſe made at our coronations, inſtallments, conſecrations, &c. nauſeend the belief of all foreigners; and yet it is doubted whether thoſe now in uſe are comparable to thoſe of our forefathers.

The Perſians never diſcourſe and deliberate of their moſt important affairs but in the middle of their *feaſts*.

FEATHER, *Pluma*, that part in birds which covers them, and by which they are enabled to fly.

Feathers make a conſiderable article in commerce, particularly thoſe of the oſtrich, heron, ſwan, peacock, [illegible], &c. for plumes, ornaments of the [illegible] of beds, writing-pens, &c.

Geeſe are plucked in [illegible] of Great Britain three times in the year; the firſt plucking is at Midſummer for *feathers* and quills, and the ſame is repeated at *feathers* only four times more between that and Michaelmas. See FEN and GOOSE. In cold ſeaſons many geeſe die by this barbarous cuſtom. Thoſe *feathers* that are brought from Somerſetſhire are eſteemed the beſt, and thoſe from Ireland the worſt. Eider down is imported into this country from Denmark, and is furniſhed by thoſe DUCKS that are inhabitants of Hudſon's Bay, Greenland, Iceland, and Norway. Hudſon's Bay alſo affords a very fine *feather*, ſuppoſed to be of the gooſe-kind. The down of the ſwan is brought from Dantzick, whence we have alſo a great quantity of cock and hen *feathers*. The beſt method of curing *feathers* is to lay them in a room in an expoſure to the ſun, and when dried to put them in bags, and beat them well with poles to diſcharge the duſt.

Feathers ſeems to be only productions and expanſions of the laſt extreme fibrillæ of the cutis; and hence, upon ſtripping off the cutis, the *feathers* are likewiſe always taken away; juſt as the leaves and fruit follow, upon peeling the bark of a tree: add, that *feathers* as well as hairs ariſe out of pores in the cutis; which pores are not mere apertures or foramina, but a kind of vaginulæ, wove of the fibres of the ſkin, which terminate in the oſcula or anaſtomoſes of the internal fibres of the *feather*.

Feathers, Dr. Derham obſerves, are a very commodious dreſs for the inhabitants of the air, being not only a guard againſt wet and cold, and a means for hatching and brooding their young, but moſt commodious for flight; to which purpoſe they are nicely placed over the body to give an eaſy paſſage, and every where neatly poſtred from the head towards the tail in cloſe uniform order; ſo that being pruned and dreſſed by an unctuous matter ſecreted in a proper gland, and depoſited in an oil-bag placed therein for that purpoſe, they afford as eaſy a paſſage through the air as a boat new cleaned and dreſſed has through the waters. Without all this nicety they would have been apt to be ruffled and diſcompoſed, and would have gathered air, and proved an obſtruction to the paſſage of the body.

Moſt of the *feathers* tend backwards, and are laid over each other in an exact method, armed with a warm and ſoft down next the body, and more ſtrongly made, as well as more curiouſly cloſed next the air and weather; to which purpoſe the *apparatus* nature has made, and the inſtinct ſhe has given them to prune or dreſs their *feathers*, are admirable.

The mechaniſm of the *feather* is wonderful; the ſhaft or rib is exceeding ſtrong, but hollow below, for ſtrength and lightneſs ſake; and above, not much leſs ſtrong, and filled with a *parenchyma* or pith both ſtrong and light.

But the vanes or webs in the flag-part of the wing are nicely gaged, broad on one ſide, and narrower on the

other, the edges of the exterior vanes bending downwards, and those of the interior or wider upwards; by which means they catch hold and lie close to each other when the wing is spread, so that not one feather may miss its full force and impulse upon the air: the tips are all made sloping; those of the interior vanes sloping to a point towards the outer-part of the wing, and the exterior vanes towards the body; so that the wing, whether extended or shut, is as neatly sloped and formed as if constantly trimmed with a pair of scissars.

Dr. Derham has several new observations on the mechanism of the vanes or webs of the *feathers* as they present themselves to the microscope, by which the wonderful care and accuracy of the Creator in so small a part are excellently illustrated.

The vane consists not of one continued membrane (because, if once broken, it would then be scarce repairable), but of many *lamina*, admirably contrived to hook and hang together. On the under side they are thin and smooth; but on their upper outer edge, (represented *Tab. Nat. Hist. fig.* 3.) they are parted into two hairy edges, each side having a different sort of hairs, laminated or broader at the bottom, and slenderer and bearded towards the top. Those bearded hairs on one side of the *lamina* have straight beards, as represented in *fig.* 4. those on the other have hooked beards on one side of the slender part of the bristle and straight ones on the other, as in *fig.* 5. Both kinds are represented as they grow on the upper edge of the lamina in *fig.* 3. in the vane; the hooked beards of one lamina always lie next the straight beards of the next lamina, by which means they lock and lay hold on each other, and by a pretty mechanism brace the lamina close to one another.

FEATHER-*bed*.
FEATHERS, *dry pulled*. } See BED.
FEATHERS, *plucked*.

FEATHER-*shaped boards and planks*, are those which are thicker on one side than on the other.

FEATHER, in the *Manege*, a sort of natural frizling of the hair found in many parts of a horse's body, but more commonly between the eyes. In some cases it resembles an ear of barley, and in others an ovate bole. Many are of opinion, that when the *feather* is lower than the eyes it is a sign of a weak eye-sight; but this remark is not certain.

FEATHER, *prince's*, in *Botany*. See AMARANTH.

FEATHER, *Roman*, called in French *epée Romaine*, is a *feather* upon a horse's neck, being a row of hair turned back and raised, which forms a mark like a sword-blade just by the mane.

FEATHER, *mid*, in the *English Salt works*. See MID.

FEATHER, *sea*. See GORGONIA.

FEAZING, at *Sea*, is the raveling out of the cable or any great rope at the ends.

FEBRIFUGE, in *Medicine*, a remedy efficacious for the cure of FEVERS.

The word is a compound of *febris* and *fugo*, *I drive away*. The *quinquina*, or Jesuit's bark, is the greatest and surest of all the class of *febrifuges*.

The little centaury is sometimes also called *febrifugum*, on account of its virtue.

The Chinese ginseng is also particularly famed as a *febrifuge*. For such as cannot take the Peruvian bark in substance, Dr. Fuller prescribes a *febrifuge* clyster, made of a decoction thereof. The inner bark of the ash-tree, with a little salt of wormwood, taken like the Peruvian bark, is said to equal, or even exceed it, as a *febrifuge*.

The like is ascribed of the bark of the elm, near the root.

The flowers of *sal armoniac* are held an excellent *febrifuge*, especially in intermitting fevers. Cold water has been much extolled as a *febrifuge*. Dr. Handcock gives it the emphatical denomination of *febrifugum magnum*.

M. Reneaume, in the Hist. de l'Academ. R. Sciences, an. 1711, proposes a new *febrifuge* of his own discovery, viz. galls. From a great number of experiments he has learnt, that galls alone will frequently cure an intermitting fever as well as the *quinquina*, over which this medicine has some advantage in other things, in that it is not so bitter, does not hurt so much, is taken in a less dose, and is cheaper. At his motion several other physicians tried it with success, particularly M. Homberg, though it did not succeed so well with M. Boulduc, Lemery, and Geoffroy. If the flowers of antimony, made with sal ammoniacum and antimony sublimated together, are exposed to the air, they produce a liquid called *febrifuge* oil. The Germans call the pulvis flypt. Hele. the *febrifuge* powder. And the same name is given in England to a mixture of cream of tartar, 5 ss. and tart. emet. gr. ii. This is administered in doses of gr. iij. to vi. The *febrifuge* salt is the sal arcan. regener.

The *febrifuge* spirit of Mr. Clutton is prepared by digesting together for a month equal parts of oil of sulphur by the bell, rectified oil of vitriol and spirit of salt, with three times the whole quantity of rectified spirit of wine, and distilling them to dryness. This spirit mixed with water, so as to render it agreeably acid, is given with common drink in ardent and inflammatory fevers, and with any cordial or antiseptic liquors in the nervous and putrid kinds.

FEBRIS, in *Medicine*. See FEVER.

FEBRIS, *ephemera*. See EPHEMERA.

FEBRIS *intestinalis*. See *Intestinal* FEVER.

FEBRUA, or FEBRUATA, in *Mythology*, an appellation given to Juno as the goddess of purification, and as presiding over women in the pains of labour and childbirth.

FEBRUA, in *Antiquity*, a feast held by the Romans in the month of February, in behalf of the MANES of the deceased. Macrobius tells us that sacrifices were here performed, and the last offices paid to the shades of the departed. Saturn. lib. i. cap. 13. And from this feast it was that the month of February took its name.

The design of these sacrifices is somewhat controverted: Pliny says they were performed to render the infernal gods propitious to the deceased; though some of the moderns have imagined that they were intended to appease the deceased themselves, and were offered immediately to them as a sort of deities. What confirms the former sentiment is, that Pluto himself is surnamed *Februus*. They lasted twelve days.

The word is of an ancient standing in the Latin tongue: from the very foundation of the city we meet with *februa* for *purifications*, and *februare*, *to purge* or *purify*. Varro, De Ling. lib. v. derives it from the Sabines: Festus, and others, from *februo*, *I am hot*, because purifications were chiefly performed with fire and hot water. Some go higher, and even deduce the words from הבר, *ebur*, or *ebavor*, which, in the Syriac and Arabic, has the same signification with *februo*, or *februor*, and might probably likewise signify *to purify*; for *ebavor*, in Arabic, denotes a preparation given to women in child-bed to bring away the after-birth, and other impurities remaining after delivery, much as among the Romans, who gave the name *Februa* to the goddess supposed to preside over the delivery of women. Ovid. Fast.

FEBRUARY, *Februarius*, in the *Roman Chronology*, the second month of their year, so called from FEBRUA, a feast held therein.

In the first ages of Rome, *February* was the last month of the year, and preceded January, till the decemviri made an order that *February* should be the second month of the year, and come after January. See BISSEXTILE.

FECES. See FÆCES.

FECIALES, or FORTIALES, an order of priests or officers, consisting of twenty persons, among the ancient Romans, appointed to proclaim war, negociate peace, &c.

Festus derives the word from *feria*, *I strike*, as *feriæ fœdus* signifies *to conclude a treaty*; and accordingly, instead of *fetiales* he would have it wrote *feriales*. Others derive it from *fœdus*, which was anciently written *fœdes*; or from *fides*, *faith*; others from *fatis*, *fari*, *I make*, &c. because they made war and peace. Vossius chooses to derive it from *fatis*, of the verb *fari*, *to speak*; in which sense the *fetiales* should be the same with *oratores*; which sentiment is also confirmed by the authority of Varro, who says they were called indifferently, *fetiales* and *oratores*. De Vit. Popul. Roman. lib. ii.

The *fetiales* were a sort of heralds or kings at arms, who, when the Romans had any dispute with their neighbours, were first to demand the thing pretended to be usurped, or require satisfaction for the injury alleged to be done. If an answer was not returned by them that was satisfactory to the people and the senate, they were dispatched again to declare war, and the like in treating of peace, the *fetiales* being the only persons appointed to negociate between the senate, &c. and the enemy.

Plutarch, in the Life of Numa, and Halicarnassæus, lib. ii. observe, that they were first instituted by that prince. The latter adds, that they were chosen out of the best families in Rome; that their office, which was reputed a sort of sacerdotium, or priesthood, only ended with their life; that their persons were sacred and inviolable, as those of other priests; that they were even charged to see the republic did not declare war unjustly; that they were to receive the complaints and remonstrances of nations who pretended to have been any way injured by the Romans; that if those complaints were found just, they were to seize the criminals, and deliver them up to those they had offended; that they were invested with the rights and privileges of ambassadors; that they concluded treaties of peace and alliance, and took care they were executed; and lastly, abolished them, as they were

found not to be equitable. Livy, lib. i. cap. 24. ascribes their inſtitution to Ancus Martius, in the year of Rome 114. See alſo Aul. Gell. lib. xvi. cap. 4.

But Varro aſſures us, that in his time moſt of theſe functions of the *faciales* were ſet aſide; as thoſe of the ancient heralds at arms are among us at preſent; though Plutarch obſerves, that they had ſtill ſome authority in his time.

The *faciales* were crowned with *verbena*, vervain, when they went to declare war: their head was covered with a veil, over which the crown was applied; in this equipage they proceeded to the frontiers of the new enemy's country, and threw a bloody dart or javelin into the ground within the ſame. In Livy, and other ancient authors, we have the formula uſed in ſuch declarations.

FECULA, or FECULA, in *Pharmacy*, a white mealy ſubſtance or powder which ſubſides and gathers at the bottom of the expreſſed juices of divers roots; as thoſe of *bryony*, arum, iris, &c.

The word *fecula* is a diminutive of FECES.

This ſubſtance or ſediment they dry in the ſun, after having pouted off the liquors, and it ſerves for divers medecines, &c.

FECULENT, or FECULENT, is applied to the blood and other humours, when they abound in feces or dregs, or have not the proper and uſual degree of purity.

FECUNDITY, or FORCEMBRITY, *fertility*, or that quality of a thing which denominates it fruitful.

The *fecundity* of divers plants is very extraordinary. M. Dodart has an expreſs diſcourſe on this ſubject, in the Memoirs of the Academy of Sciences; wherein he ſhews, that at a moderate computation, an elm, one year with another, yields 329,000 grains or ſeeds, each of which, if properly lodged, would grow up into a tree: now, an elm ordinarily lives 100 years, conſequently, in the courſe of its life it produces near 33,000,000 ſeeds, all which ariſe from one ſingle ſeed.

He ſhews farther, that the ſame elm by frequently cutting off its head, &c. might be brought to produce 15,840,000,000 ſeeds, and conſequently that there are ſo many actually contained in it.

FECUNDITY *of fiſh*. See FISH.

FEDOA, in *Zoology*, a name uſed by Geſner and ſome other authors for the GODWIT, more commonly called ÆGOCEPHALUS. See VETOLA.

FEE, FEUD, FEUDUM, FEODUM, or FIEF, an eſtate, land, tenement, lordſhip, or the like, held of a ſuperior lord, on condition of fealty, homage, or other acknowledgment.

The word is derived by ſome authors from *fœdus*, as ariſing from a treaty or alliance made with the lord; but the opinion of Selden ſeems the beſt authoriſed, who brings it from the Saxon, *feoh*, *ſtipendium*, the *fee* being a kind of prebend to live upon; and accordingly we find, that in ancient times it was uſed for the wages and appointments of officers. It is obſerved by Pontoppidan, in his Hiſtory of Norway, that in the Northern languages *ode*, ſignifies *property*, and therefore *feudeh*, or *feudum*, will denote *ſtipendiary property*.

The term *fee* is properly applied to lands and tenements, which we hold in perpetual right, on condition of an acknowledgment of ſuperiority in a higher lord. See TENURE.

The writers on this ſubject divide all lands and tenements wherein a man has a perpetual eſtate to him and his heirs into ALLODIUM and FEUDUM.

Allodium is defined to be a man's own land, which he poſſeſſes merely in his own right, without acknowledgment of any ſervice or payment of any rent to another; and this is property in the higheſt degree.

Feudum is that which we hold by the benefit of another, and for which we do ſervice or pay rent, or both to the chief lord.

Originally a *feud* was only an eſtate for life; and thoſe to whom it was granted were called *vaſſalli*, who by ſuch means were brought to a ſtricter diſcipline and obedience to the princes, and were bound to ſerve them in wars.

The origin of *fees* or *feuds* is one of the darkeſt and moſt intricate points in modern hiſtory. Some attribute the invention to the Lombards. Sir Thomas Craig inclines to this opinion, and ſays, that the Lombards, after they were ſubdued by Charlemagne, not only retained their ancient cuſtoms, but at the return of that emperor into France tranſmitted them with him into the remoteſt parts of that kingdom. In reality, the conſtitution of *feuds* had its original from the military policy of the Northern or Celtic nations, the Goths, Huns, Franks, Vandals, and Lombards, who ſpread themſelves over Europe at the declenſion of the Roman empire. This is rendered probable by the demand which the Cimbri and Teutones, nations of the ſame original, are recorded to have made on the Romans on their firſt irruption into Italy, about a century before the Chriſtian æra. They demanded of the Romans, *Ut martios populos aliquid ſibi terræ daret, quoſq; ſtipendium; caterum, ut ipſi manibus atque armis ſua uterentur*; i. e. they deſired *feuds* to be allowed them, which they were to hold by military and other perſonal ſervices. L. Florus, lib. iii. cap. 3. Having brought this conſtitution from their own countries, they continued it in their reſpective colonies as the moſt likely means to ſecure their new acquiſitions: and for this purpoſe the victorious general allotted large diſtricts of land to the ſuperior officers of the army; and theſe again diſtributed ſmaller parcels to the inferior officers and more deſerving ſoldiers. However, the *feudal* policy was only brought by degrees into that ſtate, which we find eſtabliſhed in the empire under Conrade the Salic, and in France under Hugh Capet. Sir Thomas Craig has diſtinguiſhed four ſtates of the *feudal* law: its infancy, comprehending the period between the firſt overflowing of the Northern nations and the year 650; its childhood, the time in which *fiefs*, which were before annual, or at moſt for life, were extended to the ſons of the vaſſal, and ex patre, viz. from the year 650 to the year 800, when Charlemagne was crowned emperor; its adoleſcence, from the times of Charlemagne to thoſe of Conrade II. or the Salic, who began his reign in the year 1024, and not only confirmed the inheritance of *fiefs* to the ſons and grandſons of the vaſſals, but permitted one brother to ſucceed another in his paternal eſtate; but even after the alteration made by Conrade, it was not uncommon in Germany to grant *fiefs* only for life; a charter of this kind occurs as late as the year 1376; and its maturity from this period forward, when *feuds* were permitted to deſcend to collaterals as far as the ſeventh degree. Others find ſome appearance of the duties of a vaſſal to his lord, in the ancient relation between the patron and his client; and others trace out its riſe in the Roman *Beneficia*.

The emperors, it ſeems, [illegible] among the ancient legions [illegible] ready at all [illegible] the frontiers of the [illegible] ſufficient [illegible] of *feuds*, though [illegible] their firſt origin ſhould be traced [illegible] by degrees in the progreſs of time their nature was changed, and [illegible] were annexed to them which originally were not.

Du-Moulin makes no doubt, but that theſe diſtributions of land, called *beneficia*, were the firſt matter of *fees*; for which reaſon he uſes the terms *benefice* and *feud* promiſcuouſly, as if they were the ſame thing; and yet there was a good deal of difference between them, as there was neither fealty, nor homage, nor the other *feudal* rights annexed to the benefice; and that the benefice was not hereditary.

Probably benefices began then to be called *feuds*, when they became hereditary; and when thoſe to whom the benefices were held began to demand faith and fealty from them. This fealty ſeems to conſtitute the *fee*: the word *fee* itſelf ſignifying, in the ancient Norman language, *faith*.

There is no fixing the preciſe æra when theſe changes commenced; but *fees*, ſuch as they now are, were not eſtabliſhed all at once, but in different countries they took place at different times, and in different manners. The great lords, after the deſtruction of the Roman empire, having in ſeveral parts uſurped the property of their benefices, laid likewiſe hold of the juriſdiction, and made their vaſſals their ſubjects; ſo that each became a ſort of petty ſovereign in his own territory.

Mezeray obſerves, that the donation of *fees* to the nobleſſe of France commenced under the reign of Charles Martel.

Hugh Capet, when he came to the crown, was himſelf ſo little eſtabliſhed that he durſt not oppoſe thoſe uſurpations, and was forced to ſuffer what he could not redreſs. See Le Ferre, De l'Origine des Fiefs, and Alſaferra's Origines Feudorum primordius Galliæ. See FEUDUM.

The origin of *fees* in England, Camden carries as far back as the time of Alexander Severus. That prince having built a wall in the North of England to prevent the incurſions of the Picts, he ſome time after began to neglect the defence thereof, and gave, as Lampridius, in Vita Alex. Severi, aſſures us, the lands conquered from the enemy to thoſe of his captains and ſoldiers, whom that author calls *limitaneos duces, & milites*; i. e. captains and ſoldiers of the frontiers, but it was on this condition, that their heirs ſhould continue in the ſervice, and that the lands ſhould never deſcend to private perſons, i. e. to ſuch as did not bear arms. That prince's reaſon was, that people, who in ſerving defended their own, would ſerve with a great deal more zeal than any others. Such, according to Camden, was the riſe of *fees* in our nation. Britan. p. 631.

However, the *feudal* polity originally derived from the Northern nations, and gradually eſtabliſhed on the continent of Europe, was not univerſally received in England, though ſome traces of it may be diſcerned in the times of the Saxons, who were firſtly ſettled in this iſland as early as the year 600, and incorporated with the national conſtitution till the reign of William the Norman; and this was done not by the mere arbitrary will and power of the conqueror, but by the univerſal conſent of the common council of the kingdom, on the ſame principle of ſelf-ſecurity which had before induced the other nations of Europe to adopt it. The æra of formally introducing the *feodal* tenures by law was probably the latter end of the year 1086, when the king was attended by all his nobility at Sarum, and all the principal landholders ſubmitted their lands to the yoke of military tenure, became the king's vaſſals, and did homage and fealty to his perſon. This ingraftment of the *feudal* tenures and other cuſtoms of Normandy on the ancient Saxon laws of Edward the Confeſſor produced a different political ſyſtem in this country, and changed both power and property in many reſpects; for thoſe hereditary eſtates of the Saxon nobility and gentry which were allodial, and not ſubject to any *feodal* ſervice, were converted into *feuds* and other lands which were of a *feudal* nature, and holden by military ſervice, having been granted only at will, or for a certain number of years, or at moſt for life or lives, and the grants of which were called beneſices, were made hereditary *firſt*. The *feudal* rights claimed in conſequence of this eſtabliſhment by the king over his tenants, and by them over their's, were conſiderably mitigated by the charter of Henry I. See MAGNA *charta*. Lord Lyttleton's Hiſt. of King Henry II. *vol. i.* p. 59, &c. *vol. iii.* p. 97, &c. Blackſtone's Comm. *vol. ii.* chap. 4.

All our lands in England (the crown-land, which is in the king's own hand in right of his crown, excepted) are of the nature of *feud* or *fee*. For though many have land by deſcent from their anceſtors, and others have bought lands, yet land cannot come to any, either by deſcent or purchaſe, but with the burden that was laid on him who had the novel *fee*, or who firſt received it as a beneſice from his lord to him, and ſuch as ſhould deſcend from him, or to whom it ſhould be otherwiſe conveyed and tranſferred; ſo that no man has *dorellum dominium*; i. e. the very property or demain in any land but the prince in right of his crown. Camd. Britan. p. 93. Though he who has *fee* has *jus perpetuum* and *utile dominium*, yet he owes a duty for it; ſo that it is not ſtrictly his own. Indeed, as much as is imported by the terms in which we expreſs our higheſt right in lands, &c. the moſt a man can ſay, is, "I am ſeiſed of this land in my "demain or demeſne as of *fee*."

It ſhould be obſerved, that our Engliſh lawyers do very rarely (of late years eſpecially) uſe the word *fee* in this its primary original ſenſe, in contradiſtinction to *allodium* or abſolute property, but generally uſe it to expreſs the continuance or quantity of an eſtate; ſo that a *fee* in general ſignifies an eſtate of inheritance, being the higheſt and moſt extenſive intereſt that a man can have in a *feud*. Blackſtone's Comm. *vol. ii.* p. 106.

In the ſtat. 27 Hen. VIII. cap. 16. *fee* is alſo uſed for lands veſted in the crown; but it is from ignorance of the import of the word; for *fee* cannot be without fealty ſworn to a ſuperior; but the king owns fealty to no ſuperior but God alone.

Fee is divided in our laws into *fee-abſolute*, called alſo *fee-ſimple*; and *fee-conditional*, alſo called *fee-tail*. See FEUD.

FEE, *franc*. See FRANC.

FEE-*ſimple*, *feodum ſimplex*, is that whereof we are ſeiſed to us and ours heirs for ever. Or it denotes an abſolute inheritance, clear of any condition, limitation, or reſtriction to particular heirs, but deſcendible to the heirs general, whether male or female, lineal or collateral. It is a general rule, that the word *heirs* is neceſſary in the grant or donation, in order to make a *fee* or inheritance: but this rule does not extend to deviſes by will, nor to fines and recoveries conſidered as a ſpecies of conveyance, nor to creation of nobility by writ, though in creations by patent, the word *heirs* muſt be inſerted; nor to grants of lands to ſole corporations and their ſucceſſors; nor finally, to the caſe of the king, in whom a *fee-ſimple* will veſt, without the words *heirs or ſucceſſors* in the grant.

FEE-*tail*, *feodum talliatum*, is that whereof we are ſeiſed with limitation to us and the heirs of our body. See TAIL.

Fee-tail is of two kinds, *general* and *ſpecial*.

Fee tail general, is where lands and tenements are given to a man and the heirs of his body begotten. So that if a man ſeiſed of ſuch land by ſuch gift marry one or more wives, and have no iſſue by them, and at length marry another, by whom he hath iſſue, this iſſue ſhall inherit the land.

Fee-tail ſpecial, is where a man and his wife are ſeiſed of lands to them and the heirs of their two bodies; where, in caſe the wife die without iſſue, and he marry another by whom he have iſſue, this iſſue cannot inherit the land, and therefore it is called *ſpecial tail*.

This *fee-tail ſpecial* has its origin from the ſtat. of Weſtm. 2. 13 Edw. I. cap. 1. Before that ſtatute, all land given to a man and his heirs, either *general* or *ſpecial*, was reputed in the nature of a *fee*; and therefore to firmly hold to him, that, any limitation notwithſtanding, he might alienate it at pleaſure: for redreſs of which inconvenience the ſtatute provides, that if a man gives lands in *fee*, limiting the heirs to whom it ſhall deſcend, with a reverſion to himſelf and his heirs for default of ſuch former heirs, the form and meaning of the gift ſhall be obſerved.

Eſtates, in *general* and *ſpecial tail*, are further diverſified by the diſtinction of ſexes in ſuch entailsy for both of them may be in tail-male or female: as if lands be given to a man and *his heirs male of his body begotten*, this is an eſtate in tail-male *general*; but if to a man and *the heirs female of his body on his preſent wife begotten*, this is an eſtate in tail-female *ſpecial*; and in caſe of an entail male, the heirs female ſhall never inherit, nor any derived from them; nor *e converſo*, the heirs male, in caſe of a gift in tail female. The word *body*, or ſome other words of procreation, are neceſſary to make it a *fee-tail*, and to aſcertain to what heirs in particular the *fee* is limited; though in wills and teſtaments greater indulgence is allowed. The incidents to a tenancy in tail, under the ſtatute of Weſtm. 2. are chiefly theſe: 1. That a tenant in tail may commit waſte on the eſtate-tail by felling timber, pulling down houſes, or the like, without being impeached or called to account for the ſame. 2. That the wife of the tenant in tail ſhall have her dower or thirds of the eſtate-tail. 3. That the huſband of a female tenant in tail may be tenant by the courteſy of the eſtate-tail. 4. That an eſtate-tail may be barred or deſtroyed by a FINE, by a common RECOVERY, or by lineal warranty deſcending with aſſets to the heir. By ſubſequent ſtatutes, eſtates tail may be alienated, are liable to forfeiture for high treaſon, and are chargeable with reaſonable leaſes, and with ſuch debts as are due to the crown on ſpecialties, or have been contracted with ſellow-ſubjects in a courſe of commerce.

FEE, *baſe*, *or qualified*, is a conditional *fee* that has a qualification ſubjoined to it, and which muſt be determined whenever this qualification is at an end; as in the caſe of a grant to A. and his heirs, *tenants of the manor of Dale*, whenever the heirs of A. ceaſe to be tenants of that manor, the grant is entirely defeated. Blackſtone's Comm. *vol. ii.* chap. 7. See ENTAIL.

FEE-*expectant*, *feodum expectativum*. See EXPECTANT.

FEE-*farm*, or FEE-*form*, *feud-farm*, or *fee-firma*, ſignifies lands holden to a man and his heirs for ever, under a certain yearly rent.

Fee-farm arriſes when the lord upon creation of a tenancy reſerves to himſelf and his heirs, either the rent for which it was before-let to farm, or at leaſt a fourth part of the rent, and that without homage, fealty, or other ſervices more than are eſpecially compriſed in the groſſment.

Though by Fitzherbert it appears, that the third part of the value may be appointed for the rent, or the finding of a chaplain to ſay divine ſervice, &c. And the nature of it is this: that if the rent be behind, and unpaid for the ſpace of two years, then the feoffee or his heirs have action to recover the lands as their demeſnes.

FEE-*farm rents of the crown*, are ſuch as iſſue to the kings of England from their ancient demeſnes, many of which were alienated from the crown in the reign of king Charles II.

FEE is alſo uſed for the compaſs or circuit of a manor or lordſhip. Thus Bracton, *in eodem vilo. & de eodem feodo.*

FEE is alſo uſed for a perpetual right incorporeal; as to have the keeping of perſons in *fee*, rent granted in *fee*, and office held in *fee*, &c.

FEE alſo ſignifies a reward or ordinary due given to a perſon for the execution of his office, or the performance of his part in his reſpective art or ſcience.

Thus, the lawyer, barriſter, and phyſician, are ſaid to have their *fees*; i. e. conſiderations for the pains taken with the client or patient. If a perſon refuſe to pay an officer his due *fees*, the court will grant an attachment againſt him, to be committed till the *fees* are paid; and an attorney may bring an action of the caſe for his *fees* againſt the client that retained him in his cauſe.

FEES alſo denote ſettled perquiſites or allowances paid to public

public officers by perſons who have buſineſs with them. The *fees* due to the officers of the cuſtom-houſe are expreſsly mentioned in a ſchedule or table, which is hung up to view in the ſaid office, and in all other places where the *fees* are to be paid: and if any officer ſhall offend, by acting contrary to the regulations therein contained, he ſhall forfeit his office and place, and be for ever after incapable of any office in the cuſtom-houſe.

The finalneſs of the ſalaries of divers of the king's ſervants is compenſated by the perquiſites or *fees* of honour. The *fees* paid to the ſeveral officers by every perſon upon his being knighted amount to 78*l.* 13*s.* 4*d.* And if it be done within the verge of the court, there is 3*l.* more to the ſix pages of the bed-chamber, which brings it to 81*l.*

FEE, *knight's*. See KNIGHT'S *fee*.

FEEDERS, in *Mining*, a term uſed to expreſs the ſeveral ſmall channels in the ſides of a mine ſeeming to open into it, as brooks into rivers in their courſe. The miners in moſt countries call theſe the *feeders* of the load.

FEEDING. *Foal*, in the *Manege*. See FOAL.

FEEL, in the *Manege*, they ſay to *feel* a horſe in the hand; that is, to obſerve that the will of the horſe is in the rider's hand, that he taſtes the bridle, and has a good *appui* in obeying the bit.

To *feel* a horſe upon the haunches, is to obſerve that he plies or bends them, which is contrary to leaning or throwing upon the ſhoulders.

FEELERS, *Antennæ*, in *Natural Hiſtory*, are the horns, as they are uſually called, upon the heads of inſects.

The word *antennæ* is derived from the Latin, *ante*, *before*, and *teneo*, *to hold* or *carry*; or poſſibly may have been given them from ſome ſort of reſemblance to the part of a ſhip known in navigation by the ſame name. The *antennæ* in various inſects are extremely various, and in moſt very beautiful; they not only differ in the inſects of different claſſes, but frequently in the different genera of the ſame claſs, though never in the ſame ſpecies.

The *antennæ* of flies may ſerve to diſtinguiſh ſeveral genera of thoſe inſects: 1. There are ſome which have articulated ones, formed of ſeveral vertebræ of different ſize, joined end to end, like the beads in a necklace: theſe *antennæ* are thicker at their origin than at their extremity. 2. The *antennæ* of others, formed in the ſame manner, are ſmalleſt at their inſertion and increaſe in ſize towards their extremities. 3. Thoſe of others are in form of feathered beards. 4. Others have priſmatic *antennæ*, which are articulated, and leaſt in both their extremes, and largeſt in the middle. 5. The *antennæ* of another claſs are branched or forked, compoſed of two pieces, and appearing double. 6. Others have extremely ſlender and thick *antennæ*, formed of two or three articulations or beads, terminated by a larger one of the figure of a battledore. 7. The *antennæ* of thoſe two-winged flies that ſuck the blood of oxen or horſes, reſemble the battledore *antennæ*, except that the body which terminates them has ſomewhat of the figure of a creſcent, the end of which appears, by means of glaſſes, articulated. Reaum. Hiſt. Inſects. vol. iv. p. 138, &c.

The ſize of the *antennæ* of ſome flies may alſo ſerve for a diſtinction, as may alſo the manner in which they carry them. The ichneumon flies have theirs in continual motion, making a kind of inceſſant vibrations with them.

The *antennæ* are of very various forms and ſhapes in different genera of the ſame claſs of animals, and are very judiciouſly made by Reaumur the characters of different genera of the butterfly kinds, among which there is almoſt an infinite variety of them.

The *antennæ* of inſects in general differ from horns, in that they are moveable at the baſe; and have beſide that power a number of articulations all along their ſtructure, by means of which they are alſo capable of being turned about any way at the pleaſure of the animal. The differences of their figure and ſtructure in the butterfly claſs, which are made the marks of the different genera, are theſe. Thoſe of the firſt genus are equally thick throughout, of a cylindric form, but terminated by a large head, altogether reſembling a club: ſome have called them clavated *antennæ*; Reaumur calls them buttoned *antennæ*: the buttons by which they are terminated are of a very different figure in the various ſpecies. The *antennæ* of the ſecond genus are, in general, much ſhorter in proportion to the body of the animal than the former: they gradually increaſe in thickneſs from their inſertion towards their extremity, and are terminated by a ſlender ſpine iſſuing from the lower part, and ornamented with a tuft of hairs: Reaumur calls theſe the club *antennæ*. Thoſe of the third genus firſt increaſe in ſize, and then taper to an oval point, unfurniſhed with a cluſter of hairs: ſome ſpecies have their *antennæ* twiſted like the horns of a ram. The *antennæ* of the fourth genus, at a little diſtance from their origin, become very thick, and continue of the ſame ſize through the greateſt part of their length, where they turn a little, and terminate in a ſharp point, which ſometimes ſupports another point, formed of a cluſter of hairs, in the manner of a pencil. Mr. Reaumur has called theſe the priſmatic *antennæ*. Thoſe of the fifth genus are, from their ſhape, called the conic or quadrated *antennæ*. Thoſe of the ſixth genus are denominated the plumoſe or feathered *antennæ*: they appear to be compoſed of a ſtalk or pedicle, which diminiſhes in ſize from the baſis to the extremity; on each ſide of which there iſſue plumes, placed like thoſe on the barrel of a quill, but not ſo cloſe together. The plumes of the males of this genus are larger and more beautiful than thoſe of the females.

The *antennæ* are many of them put together with great artifice and nicety; but we are yet at a loſs to know to what end or purpoſe theſe nice organizations were given them. Different people have formed very different gueſſes as to their uſes. Some have thought them intended to defend the eyes; but though this might ſeem probable in regard to the ſhort plumoſe ones, it can never hold good in the ſlender and ſmooth ones, which can be of no ſuch ſervice. Others have thought them made for wiping and cleaning the eyes; but this is an unneceſſary office, and one they are wholly unfit for; and the fore-legs of the creature are always ready for ſuch a purpoſe, and are rendered much fitter for it by the hairs with which they are covered, than the *antennæ*, which in moſt caſes are compoſed of joints, and are by no means adapted to ſuch uſes. Others have called them *feelers*, and ſuppoſed that the creature uſed them as a blind man does his ſtaff, to feel out the way, leſt it ſhould run againſt any thing that would hurt it. But theſe creatures have eyes enough to ſee with; and any one who will obſerve them while they walk, will find that they do not protrude theſe before them, but often keep them erect upon the head. If this were their uſe [illegible] eaſy to ſee that all their beautiful [illegible] would not have been neceſſary. [illegible] the organs of ſmelling, [illegible] many inſects have this [illegible] and yet we ſee no reaſon [illegible] to leave for it. It is poſſible that [illegible] be their uſe, but it is mere conjecture; and as the bodies of inſects are throughout made of parts ſo different from ours, that we can probably form no more idea of the uſe of their organs than a man born deaf can of that of the ear. They may have ſenſes different from ours, and theſe may be the organs of them, or the hearing or ſmell may be performed by them.

The pedicles or ſtalks of the ſeveral *antennæ* of butterflies are always hollow, and many of them are ſmooth and gloſſy, reſembling horn. Of this kind are moſt of the plumoſe *antennæ*; and the buttons of the *antennæ* of thoſe kinds which have ſuch are always fleſhy and juicy; ſo that when preſſed, different fluids are forced out of them, firſt a white, then a yellow one, and finally a black. When the creature is held under water with only the *antennæ* above, it is common to ſee bubbles of air diſcharged from the joints and buttons; how far theſe obſervations may aſſiſt in determining their uſe, is left to farther inquiries.

FEELING, *Touching*, one of the external ſenſes, whereby we acquire the ideas of ſolid, hard, ſoft, rough, hot, cold, wet, dry, or other tangible qualities; as alſo of diſtance, itching, pain, &c.

Feeling is the groſſeſt, but at the ſame time the moſt extenſive of our ſenſes, having more objects than all the reſt taken together; and ſome even reduce all the other ſenſes to this one of *feeling*.

Ariſtotle is expreſs, that all ſenſation is only *feeling*; and that the other ſenſes, as ſeeing, hearing, taſting, and ſmelling, are only the more exquiſite ſpecies, or peculiar modes thereof. De Anim. lib. ii. cap. 3. and lib. iii. cap. 12.

Naturaliſts are divided as to the organ or inſtrument of *feeling*. Ariſtotle takes this ſenſe to reſide in the fleſh, *quatenus fleſh*, inaſmuch, as all fleſh is, in ſome meaſure, capable of *feeling*. Hiſt. Anim. lib. i. cap. 4. Others will have it in all the parts that have nervous fibres, which extends it to the ſkin, fleſh, muſcles, membranes, and parenchymas; others reſtrain it to the ſkin or cutis; it being obſerved, that only thoſe parts covered with a cutis have properly the faculty of touching, or perceiving tangible qualities.

But what part of the cutis to aſſign immediately for this office is again diſputed. Some will have it the membranous parts; others the carunculæ; and others the medullary part, derived from the nerves.

Malpighi, and after him all our acuteſt and beſt authors, hold the immediate organ of the ſenſe of *feeling* to be the pyramidal papillæ under the ſkin.

Theſe papillæ are little, ſoft, medullary, nervous promi-

nences, lodged every where immediately under the cuticula. They are formed of the subcutaneous nerves, which, for this purpose, firſt lay aſide their outer membrane, and are left exceedingly ſoft and ſenſible; are continually moiſtened by a thin fubtle humour, and only covered over and defended by the cuticle or ſcarf-ſkin. They are largeſt and moſt conſpicuous in thoſe parts chiefly deſigned for the office of *feeling*, viz. the tongue, the tips of the fingers and toes; and are contractile, and again expanſive at pleaſure.

Feeling, then, is thus effected: the tip of the finger, for inſtance, being applied to an object to be examined, by that intention of the mind the papillæ are emitted or elevated, and being ſlightly rubbed over the ſurface of the object, a motion is impreſſed on them, which being thence propagated by the nerves communicating with them to the common ſenſory, excites the perception of heat, cold, hardneſs, or the like.

Hence we ſee why *feeling* becomes painful when the cuticle is worn off, burnt, macerated, &c. and why, when the cuticle becomes thick, hard, callous, or cicatrized, &c. the ſenſe of *feeling* is loſt; elſe whence the numbneſs impreſſed by the torpedo? why that exquiſite painfulneſs under and at the roots of the nails? &c.

Feeling is, on many accounts, the moſt univerſal of our ſenſes, there being no animal without it. Pliny obſerves, that all animals have the ſenſe of *feeling*, even thoſe that are generally thought to have no other ſenſe, as oyſters and earth-worms. That naturaliſt declares it his own opinion, that all have the ſenſe of taſting likewiſe: *Exiſtimaverim omnibus ſenſum & guſtatum eſſe.* Nat. Hiſt. lib. x. cap. 71.

Naturaliſts obſerve, that ſpiders, flies, and ants, have the ſenſe of feeling in a much greater perfection than men, though we have inſtances of perſons who could diſtinguiſh colours by their *feeling*, and others who could perceive what people ſaid by the ſame ſenſe. See DEADNESS.

FEIGNED *Action*, in Law. See FAINT *action*.

FEIGNED *iſſue*. See *Feigned* Issue.

FEINT, in *Fencing*, a falſe attack, or ſhew of making a ſtroke or puſh in one part, with deſign to bring the enemy to guard that part, and leave ſome other part unguarded where the ſtroke is really intended.

Feints are either ſingle or double, high or low, without or within, &c. in prime, in tierce, in quart, in demi, and in the whole circle; of one, two, or three meaſures.

The *ſimple feint*, is a mere motion of the wriſt, without ſtirring the foot, &c.

FEINT, in *Muſic*, a ſemi-tone; the ſame with what we alſo call DIESIS.

FEINT, in *Rhetoric*, a figure whereby the ſpeaker touches on ſomething, in making a ſhew of paſſing it over in ſilence. The Latins call this *prætermiſſio*.

FEL, in the *Materia Medica of the Ancients*, the name of a fruit much uſed by them in ſtomachic medicines, but very badly deſcribed to us. All that we know of the matter is, that there were three fruits brought from the Indies at that time, and called *bel*, *fel*, and BEL; they were all of the ſame virtues, and ſeemed nearly alſied to each other in all reſpects. Serapio tells us, that the fruit *fel* was about the ſize of the piſtachia nut, and ſomewhat reſembled it in ſhape; and Avicenna obſerves, that it was an Indian medicine, bitter, and hot like ginger; and that it was uſed as a ſtomachic. He alſo ſays the ſame thing of the two other fruits; whence it appears, they were nearly the ſame thing.

FEL, in *Medicine*, ſee GALL.

FEL *terræ*, *gall of the earth*, a name by which ſome authors have called the ſmall centaury, becauſe of its great bitterneſs.

FELAGUS, in our *Law Books*, was uſed for a companion, or friend, who was bound in the decennary for the good behaviour of another. In the laws of king Ina, it is ſaid, if a murderer could not be found, the parents of the perſon ſlain ſhould have ſix marks, and the king forty; if he had no parents, then the lord ſhould have it; *et ſi dominus non habet, ſeliagus ejus.* Leg. Inæ, cap. 15.

Felagus is ſaid to be, *quaſi fide cum eo ligatus.*

FELAPTON, in *Logic*, one of the moods of ſyllogiſms. In a ſyllogiſm in *felapton*, the firſt propoſition is an univerſal negative; the ſecond, an univerſal affirmative; and the third a particular negative.

FELE *homagers*, was anciently uſed for the faithful ſubjects. But it ſeems the word ſhould be written FEAL homagers.

FELIA, a name by which ſome of the chemical writers have called the ſulphurated, or ſulphureous waters.

FELIS, in the Linnæan ſyſtem of *Zoology*, the name of a large genus of quadrupeds, of the order of the *feræ*; the characters of which are theſe: the fore-teeth are ſmall, obtuſe, and equal; they have three grinders; the tongue is furniſhed with prickles, all pointing backward; and the feet are formed for climbing, with claws which may be drawn in or exerted at pleaſure.

To this genus belong the lion, tiger, leopard, cat of the mountain, lynx, ounce, and domeſtic cat; which ſee under their reſpective heads.

FELIS *volans*, the *flying-cat*, in *Natural Hiſtory*, the name of an animal deſcribed by Scaliger, and ſuppoſed to be what we now call the flying SQUIRREL, a ſpecies of ſquirrel which has a looſe membrane on each ſide, connecting the foſe with the hinder legs, which it can diſtend at pleaſure, and by means of which it takes ſuch long leaps, that it ſeems to fly.

FELIS *zibethina*, in *Zoology*, a name given by many to the creature which produces the perfume called civet, and which we uſually call the CIVET-*cat*, being, in the Linnæan ſyſtem, a ſpecies of the VIVERRA. See *Tab.* II. *Quadrupeds*, N° 17.

FELLING *of Timber*. See TIMBER.

FELLOWS, or FELLIES, in *Artillery*, are ſix pieces of wood, each of which forms an arch of a circle, and theſe joined all together by dudeges, make an entire circle; which, with a nave, and twelve ſpokes, form the WHEEL of a gun carriage.

Their thickneſs is uſually the diameter of the ball of the gun they ſerve for, and their breadth ſomething more. Their dimenſions are as follow; for a 24 pounder, 5 inches thick, and 6½ inches broad; for a 12 pounder, 4½ inches thick, and 6 inches broad; for a 6 pounder, 4 inches thick, and 5½ broad, &c. made of dry elm.

FELLOWSHIP, *Company*, or *Partnerſhip*, in *Arithmetic*, is a rule of great uſe in balancing accounts amongſt merchants and owners of ſhips; where a number of perſons putting together a general ſtock, it is required to give every one his proportional ſhare of loſs, or gain.

The *golden rule*, ſeveral times repeated, is the baſis of *fellowſhip*, and fully anſwers all queſtions of that kind: for, as the whole ſtock is to the total thereby gained, or loſt; ſo each man's particular ſhare is to his proper ſhare of loſs or gain. Wherefore, the ſeveral ſums of money of every partner are to be gathered into one ſum, for the firſt term; the common gain, or loſs, for the ſecond, and every man's particular ſhare for the third; and the golden rule is then to be wrought ſo many times as there are partners.

There are two caſes of this rule, the one *without*, the other *with time*.

FELLOWSHIP *without time*, is where the quantity of ſtock, contributed by each perſon, is alone conſidered; without any particular regard to the length of time that any of their monies were employed. An example will make this proceſs eaſy.

A. B. and C. freight a ſhip with 212 ton of wine; A. laying out 1342*l.* B. 1178*l.* and C. 630*l.* towards the ſame; the whole cargo is ſold at 3*l.* per ton. Query, what ſhall each perſon receive?

Find the whole produce of the wine by multiplying 212 by 32, which yields 6784. Then adding together the ſeveral ſtocks, 1342, 1178, and 630, which make 3150, the work will ſtand thus:

3150 : 6784 :: { 1342—Anſw.—2890,1993, &c. / 1178 ——— 2537,6006, &c. / 630 ——— 1356,8

Proof 3150 6784

FELLOWSHIP *with time*, is where the time wherein the money, &c. were employed, enters into the account. An example will make it clear.

A. B. C. commence a partnerſhip the firſt of January, for a whole year. A. the ſame day diſburſed 100*l.* whereof he received back again, on the firſt of April, 20*l.* B. pays, on the firſt of March, 60*l.* and more, the firſt of Auguſt, 100*l.* C. pays, the firſt of July, 140*l.* and, the firſt of October, withdraws 40*l.* At the year's end their clear gain is 142*l.* Query, what is each perſon's due?

A.'s 100*l.* multiplied by three months, the time it was in, makes 300*l.* and the remaining 80, by nine months = 720, in all 1020*l.* of A.'s contribution. For B. 60 into 10, gives 600; and 100 into 3, 300: in all 1100*l.* for B. For C. 140 into 3, gives 420; and 100 into 3, is 300: in all 720*l.* for C. Now, 1020 + 1100 + 720 = 2840 for the common antecedent, and the gain 142, is for the general conſequent; the rule will ſtand thus:

2840 : 142 :: { 1020—Anſw. 51 / 1100 ——— 55 / 720 ——— 36

Proof 2840 142

N. B. All the particular times (if not ſo given) muſt be reduced into one denomination, viz. into years, months, weeks, or days.

FELL-*wort*, in *Botany*. See GENTIAN.

FELO *de se*, is he that commits felony, by willingly and deliberately killing himself. The Saxons call him *self-bane*. He must be of the age of discretion, and *compos mentis*.

A *felo de se* is to be interred without Christian burial, with a stake driven through his corpse; and is to forfeit his goods and chattles real and personal; but he may make a devise of his lands, because they are not subjected to any forfeiture. However, these forfeitures are generally saved by the verdict of the coroner's jury, who find lunacy. See SUICIDE.

If a person *felo de se* is secretly made away with, so that the coroner cannot view his body, presentment is to be made of it by justices of peace, &c. in order to entitle the king to the forfeiture of goods.

FELON, in *Surgery*. See WHITLOW.

FELON-*wort*. See NIGHTSHADE.

FELONY, FELONIA, was anciently used for a violent and injurious action of a vassal, or tenant, against his lord.

Menage derives the word from *felonia*, formed of *fel*, or *felle*, which occurs in the capitulars of Charles the Bald, and is supposed to come from the German *felen*, or Saxon *fealen*, *to fail*, or *be delinquent*. Others derive it from the barbarous Latin *vellania*. Lord Coke, Nicod, &c. derive it *a felle*, *gall*, as being supposed to be done maliciously. Others derive it from the Greek φηλεω, *to deceive*. But the learned Spelman, with greater probability, deduces it from two northern words, viz. *fe*, which signifies *fief*, *feud*, or *beneficiary estate*, and *lon*, which signifies *price* or *value*; so that *felony* is the same as *pretium feudi*, the consideration for which a man gives up his fief; agreeable to the common expression, such an act is as much as your life, or estate, is worth.

In this sense *felony* was equivalent to petty-treason, or it was a crime next below high-treason. The crime of *felony* imported confiscation of the fee, to the profit of the lord.

All those acts, whether of a criminal nature or not, which at this day are generally forfeitures of copy-hold estates, are styled *felonies* in the feudal law.

FELONY was also applied to an injury of the lord to his vassal, which imported a forfeiture of the homage and service thereof, and made it revert to the sovereign.

Fidelity and *felony* are reciprocal between the LORD and the vassal.

FELONY is also used, in *Common Law*, for any capital offence, perpetrated with an evil intention.

Though capital punishment does by no means enter into the true idea and definition of *felony*, the true criterion of which is forfeiture; for in all *felonies* which are punishable with death, the offender loses all his lands in fee-simple, and also all his goods and chattels; but in such as are not so punishable, his goods and chattels only.

In a stricter sense, *felony* denotes all capital crimes below treason.

Felony includes several species of crimes, whose punishment is the same, viz. death: such as petit-treason, murder, theft, homicide, sodomy, rape, wilful burning of houses, receiving of stolen goods; breach of prison, rescue and escape, after one is arrested or imprisoned for *felony*, and divers others found in the statutes, which are daily making crimes *felony*, that were not so before.

Felony by the common law is against the life of a man, as murder, manslaughter, felo de se, se defendendo, &c. against a man's goods, such as larceny and robbery; against his habitation, as arson and burglary; and against public justice, as breach of prison.

Piracy, robbery, or murder upon the seas, are *felonies* punishable by the civil law, and also by statute.

Felony is easily distinguished from treason.

From lesser crimes it is distinguished by this, that its punishment is death, though not universally; for petty-larceny, i. e. stealing of a thing under the value of twelve-pence, is *felony*, according to Brook, though the crime be not capital, but only a loss of goods. The reason Brook gives for its being *felony* is, that the indictment runs, *felonice cepit*.

Till the reign of Henry I. *felonies* were punished by pecuniary fines; that prince first ordered *felons* to be hanged, about the year 1108.

Felony is of two kinds; the one *lighter*, which for the first time is entitled to the benefit of CLERGY; as manslaughter. The other more heinous, is not allowed the privilege.

Felony is also punishable by loss of all lands, not intailed; and all goods and chattels, both real and personal; though the statutes make a difference in some cases concerning lands, as appears by stat. 37 Hen. VIII.

Felony ordinarily works corruption of blood, unless the statute, ordaining the offence to be *felony*, provide otherwise; as in the stat. 39 Eliz. cap. 15.

Persons indicted of *felony*, &c. where there are strong presumptions and circumstances of guilt, are not replevisable, but for larceny, &c. when persons are committed, who are of good reputation, they may be bailed.

FELONY, *appeal of*. See APPEAL.

FELONY, *compounding of*. See LIMITATION.

FELONY, *discovery of*. See DISCOVERY.

FELONY, *misprision of*. See MISPRISION.

FELT, a kind of stuff, either of wool alone, or of wool and hair; neither spun, crossed, nor woven, but deriving all its consistence from its being wrought, and fulled with lees and size, and afterwards fashioned on a block or mould, by help of fire and water.

Castors, camels, and coney's hair, lambs, and sheeps wool, &c. are the most usual ingredients of *felts*; and hats of all kinds are the works they are chiefly employed in.

The *felt* intended for a hat, being sufficiently fulled, and prepared, is reduced into one piece, somewhat in the figure of a large funnel; in which state it remains ready to be put into form, and become a HAT.

FELUCCA, or FELUCCO, a little vessel with from ten to fifteen banks of oars, not covered over, much used in the Mediterranean as a passage boat. The natives of Barbary employ boats of this sort as cruisers.

The word is formed from the Arabic *felem*, *a ship*.

It has this peculiarity, that the rudder may be applied either in the head or sterns; there being dispositions in both to receive it. For size, it may be compared to a sloop or shallop.

FEMALE, the sex that conceives and bears fruit.

An animal that generates within itself, is called *female*; and that which generates in another, *male*.

The *female* in quadrupeds, and even [illegible] usually smaller and weaker than the *male*; [illegible] birds of prey, as the falcon, [illegible] *female* being bigger, [illegible] more courageous.

The like is observed in [illegible] particularly, [illegible] to their degrees, the Muscovy drakes are the best weighed five or six male garden-spiders against one *female* of the same species, which has been equal to them all.

For the numeral proportion of males to *females*, see MARRIAGE.

Naturalists also distinguish male and *female* plants; male and *female* flowers, &c.

FEMALE *screw*. See SCREW.

FEMBLE, the name given by the common people of Lincolnshire to the female hemp. There is no country where hemp succeeds better than in this, and great quantities are annually raised there.

FEME *covert*, in *Law*, denotes a married woman; who is also said to be under covert-baron.

By the law of England, a *feme covert* committing a bare theft in company with, or by coercion of her husband, is not deemed guilty of felony; neither does she become accessary to a felony, by receiving her husband who has been guilty of it, as he does by receiving her. But if she commit a theft by the bare command of her husband; or treason, murder, or robbery, in his company, or by his coercion, or keep a bawdy-house with him, she is punishable in the same manner, as if she was sole; and generally if she be guilty of any offence not capital, she may be indicted, &c. without making the husband a party. But if she incur the forfeiture of a penal statute, the husband must be made defendant in the action or information. Hawk. Pl. of the Crown, book i. chap. 1. See COVERTURE.

FEME *sole*, an unmarried woman, whose debts contracted before marriage become those of her husband after it. See CUSTOM of *London*.

FEMININE, or FOEMININE, in *Grammar*, one of the genders of nouns.

The *feminine* gender is that which denotes the noun or name to belong to a female. In the Latin, the *feminine* gender is formed of the masculine, by altering its termination; particularly by changing *us* into *a*. Thus, of the masculine *bonus equus*, *a good horse*, is formed the *feminine*, *bona equa*, *a good mare*; so, of *parvus homo*, *a little man*, is formed *parva femina*, *a little woman*, &c.

In French, the *feminine* gender is expressed, not by a different termination, but a different article: that *le* is joined to a male, and *la* to a female.

In English, we are generally more strict, and express the difference of sex, not by different terminations, nor by different particles, but different words: as *boar* and *sow*, *boy* and *girl*, *brother* and *sister*, &c. though sometimes the *feminine* is formed by varying the termination of the male into *ess*; as in *abbot*, *abbess*, &c.

FEMI-

FEMININE *rhymes*. See RHYME.

FEMOREUS, in *Anatomy*, a name given by ſome of the authors on thoſe ſubjects to a muſcle, more generally called the CRURÆUS or *cruralis*.

FEMORIS *quartus*, in *Anatomy*, a name given by Veſalius and others to one of the muſcles of the thigh, called by the later writers from its ſhape *pyriformis*.

FEMORIS *ſextus*, in *Anatomy*, a name given by Spigelius and others to a muſcle, now generally called the ILIACUS *internus*.

FEM-OWL, an Engliſh name uſed in Shropſhire, and ſome other counties, for the *caprimulgus*, or goat-ſucker, called alſo the *churn*-OWL. It is a very beautiful bird, and more reſembles the cuckow than the owl-kind.

FEMUR, or *Os* FEMORIS, in *Anatomy*, the thigh-bone. See *Tab. Anat. (Oſteol.) fig.* 3. *n.* 20. and *fig.* 7. *n.* 22. See Os.

Dionis derives the word *femur*, from *fero*, becauſe it bears the whole weight of the body.

The *femur* is the largeſt and ſtrongeſt bone in the body, and its articulations are proportioned to its bulk and ſtrength. Its upper part is jointed with the *iſchium*, by enarthroſis, the head of the *femur* being received into a cavity of the *iſchium*; and the two kept together by a ſtrong cartilage or bandage. The lower end is articulated with the *tibia* by *ginglymus*, two heads of the *femur* being received into two cavities of the *tibia*; beſide a cavity between the two heads, which receives a proceſs of the *tibia*.

The *femur* is pretty much incurvated, or bent, the convex part being before, and the concave behind. It is divided into three parts; the *upper*, the *middle*, and the *lower*.

The *upper* conſiſts of a head and a neck, and two tuberoſities; the extremity or head is round and big, and received into the *acetabulum* of the coxendix, wherein it is tied by two ligaments; the one from the top, the other from the bottom of the *acetabulum*, but both inſerted into the middle of the head. This head is an epiphyſis in children, and in ſome ſubjects remains ſo for a long time, and is therefore liable to be ſeparated from the neck by any violent force. Immediately under the head is the neck of the *femur*, which is a ſmall, long and a little oval apophyſis, making an angle with the body of the bone; by means whereof the thighs and feet are kept at a due diſtance from each other, to make our ſtanding the firmer; beſide that the obliquity of the neck conduces to the ſtrength of the muſcles, which muſt otherwiſe have paſſed too near the centre of motion. The two tuberoſities are called the greater and leſs *trochanters*.

The *middle* part or ſhank of the *femur* is round, ſmooth, and poliſhed on its fore-ſide, and rough on the hind-ſide; along which there runs a ſmall ridge, the whole length of the bone, called *linea aſpera*, ſerving for the inſertion of muſcles.

The lower part of the *femur* is divided by a ſinus in the middle, into two heads or apophyſes, called *condyli*, which make the *ginglymus* above mentioned; being both received into the ſinus of the *tibia*.

Between the hind-parts of the head is a ſpace for the paſſage of the great veſſels and nerves, which go to the leg.

The *femur* has a very large cavity, running its whole length, filled, like the reſt, with marrow. The curvity of the *femur* makes it ſerve as a buttreſs to the body, to prevent its falling, or bearing too much forward.

Surgeons and bone-ſetters ſhould take care, that in fractures of the *femur* they do not endeavour to ſet it ſtraight, which is againſt nature. See THIGH.

Cartilages of the Os FEMORIS. No part of the *os femoris* is covered, except the uniform convexity of the head, and the articular portion of the lower extremity. The trochanters have no true cartilage, what appears like it being only the remains of tendinous inſertions; the cartilaginous ſubſtance, which to a certain age unites the *apophyſes* to the body of the bone, does not belong to theſe, becauſe it is only found in the time of youth, and in adults is converted into a bone. The cartilaginous matter, by which the head of the *os femoris* is cemented, deſerves, however, to be obſerved here, becauſe that *apophyſis* has been ſeparated by violent falls. The convexity of the head of the *os femoris*, all the way to its ſymphyſis with the neck, is covered with a very ſmooth, ſhining cartilage. A little below the middle of this convexity, and ſomething toward the back part, there is a depreſſion in the ſhape of a creſcent, the cartilage being here interrupted by the inſertion of the internal articular ligament of the head of the *os femoris*. The cartilage which covers the lower extremity of the bone is exactly fitted to the ſemi-oval convexity of the inferior ſurface of each condyle, and to the pulley formed by their union. Wiſlow's Anatomy, vol. i. p. 126.

Ligaments of the Os FEMORIS. The *os femoris* is connected by its upper extremity to the *os innominatum*, and by the lower to the bones of the leg, by means of ſeveral ligaments. The ligaments of the upper extremity are two in number, one which ſurrounds the whole articulation thereof, with the cotyloide cavity, and one contained in the articulation. The firſt is termed the orbicular ligament of the head of the *os femoris*; the other the internal ligament; and to theſe may be, though but improperly, added a third, which is of the nature of a capſular ligament. The orbicular ligament is the moſt conſiderable, the largeſt, and the ſtrongeſt, of all the articular ligaments of the human body; it is fixed quite round the border of the cotyloide cavity, and is made up of ſeveral ſorts of fibres, and is much ſtronger and thicker in ſome parts than in others; the other, or internal ligament of the head of the *os femoris*, reſembles a flat cord, and is compoſed of a bundle of fat fibres, cloſely interwoven. The ligaments of the lower extremity of the *os femoris*, by which this bone is connected with the leg, are ſix in number, one poſterior, two lateral, the middle, or crucial, and the capſular. The crucial ligaments lie within the joint, and are fixed by one end to the back part of the notch, or opening, which parts the two condyles; theſe are ſurrounded by the capſular ligament, but all the reſt lie on the outſide thereof, being cloſely joined to it. Of the two lateral ligaments, one is internal and broad, being fixed to the tuberoſity of the internal condyle; the other is external, and narrow, and is fixed to the tuberoſity of the external condyle. The poſterior ligament is broad and thin, and being fixed a little above the convexity of the external condyle, it thence deſcends obliquely behind the great notch, and external condyle. The capſular ligament is, as it were, glued to the three former, and is fixed quite round the inferior extremity of the *os femoris*; at a ſmall diſtance above the anterior, lateral, and poſterior parts of the cartilage, and above the poſterior part of the great notch; and from the cartilage and notch, through the ſmall ſpace upward already mentioned, it covers the bone, and afterwards is inverted downwards, to form the capſula for the mucilaginous liquor of the joints. Wiſlow's Anatomy, p. 126, &c.

FEMUR *mentulum ſeptum*, in *Anatomy*, the name given by Veſalius and ſome others, to the muſcle now called the *penis tegens*.

FEN, in *Geography*, a kind of wet land, or rather morſs. *Fens* are of two ſorts; the firſt of a boggy conſiſtence, compoſed of water and earth intermixed, ſcarce firm enough to ſuſtain the tread of a man.

The ſecond are pools, or collections of water, with pieces of dry land raiſed here and there, above the ſurface thereof.

The former kind neither receive nor emit any rivers; but the latter are frequently the heads or ſprings of rivers; ſuch is the head of the Lavant, &c.

What the farmers call *fens* or *ſeavy lands*, are of two kinds: firſt, thoſe which are only drowned by upland floods and great rains, and are very large and lie upon the levels, ſo that the water cannot run off from them, but muſt be there till the hot weather and winds dry it off; and, ſecondly, thoſe that are conſtantly wet, only that in dry times they are covered with ſhallower water than in others. In draining of theſe ſorts of lands, which is the only means of making them uſeful to the public, two things are to be conſidered, firſt, the laying of them perfectly dry, which can only be effected by making cuts and drains, for carrying off the water from their loweſt parts, and them e from the whole. Or ſecondly, the taking off from them the great additional wetting they have from land floods, and long continued rains. The firſt method makes a perfect cure, the other is only a temporary relief, and makes the lands more ſerviceable in dry times, and leaves leſs for the ſun to dry up.

Whatever is attempted in regard to the draining of *fens*, the loweſt part of the ground is to be found out firſt, and the overflowing from great rains, and from land floods, muſt be provided for, in carrying off that way; for ſhould this be neglected, all the labour and coſt employed on the other principle would be thrown away. If it is found that this can be done, there muſt afterwards be cut a large drain through the middle of the land, and ſeveral ſmaller drains from all parts communicating with this.

The great drain muſt be dug deep enough to drain the whole level; and this, and all the others, muſt be made narroweſt at the head, and wider all the way to the mouth, where they muſt be wideſt of all.

Theſe drains muſt be all well cleanſed from muſſ and weeds every ſpring and autumn, and the water from land floods muſt be kept from coming in upon theſe lands, as much as poſſible, that there may be the leſs to be drained off

off; the lower edges of the *fen* land muſt be for this purpoſe guarded with banks to turn the water into other channels. In Eſſex they have many lands that lie below the high-water mark, and are above the low-water mark, and have land floods or fleets running through them, which make a ſort of ſmall creek. Theſe lands they have a very eaſy way of draining, though they are naturally very moiſt when they firſt incloſe them from the ſea; they do it with a bank, which they extend from one ſide of the land they deſign to take in to the other, excepting a ſpace that they leave, where the creek, or land flood, runs into the ſea. They then prepare a wooden frame, well planked, and of conſiderable thickneſs, fitted to the head of the creek, and capable of ſhutting it wholly up; in this frame they make ſeveral holes, in which are placed wooden troughs, made each of four boards, and fitted in ſize and number to the quantity of water that is to be diſcharged through them from the land floods. Each of theſe trunks is open toward the creek; but on the ſea-ſide it has a door or flap, which opens when the land flood preſſes againſt it, and gives it free paſſage out; but when the ſea-water is riſen to the height of it, and preſſes it, is ſhut by the force, and no ſea-water is let in. When this head is prepared, they let it in, and ſtopping up the whole creek, they continue the banks on each ſide till they meet it: thus all the land floods are let out at low water, and not a drop of ſea-water can be admitted, ſo that the lands are kept dry and uſeful, which were before rendered uſeleſs, by being drowned with ſalt-water, at every high-water mark. The freſh-water of the creek is thus kept unmixed with the ſea-water, and therefore affords good drink for the cattle, which is commonly very difficult to be had in this ſort of lands, the tides ſpoiling what freſh waters there are every time they come up.

Several ſtatutes have been made for draining fens, chiefly in Kent, Cambridgeſhire, Bedfordſhire, and Lincolnſhire, 4 Jac. I. cap. 8. & 23. 15 Car. II. cap. 17. 16. 17 Car. II. cap. 11. 11 Geo. II. cap. 34. & cap. 37. 21 Geo. II. cap. 18. & 22 Geo. II. cap. 11. 16. & 19.

The wet grounds called *fens*, in Lincolnſhire and elſewhere in England, bring many advantages to the inhabitants of thoſe counties. Fowl and fiſh are very plentiful in them. The pike and eels are large and eaſily caught, but they are uſually courſe. The duck, mallard, and teal, are in ſuch plenty, as is ſcarce to be conceived; they are taken in DECOYS, by prodigious flocks at a time. They ſend theſe fowl to London from Lincolnſhire, twice a week on horſeback, from Michaelmas to Lady-day; and one decoy will furniſh twenty dozen, or more, twice a week, for the whole ſeaſon, in this manner. The decoy-men contract with the people who bring them to London, at a certain rate, and they are obliged to take the whole number that is catched off their hands. Two teals are uſually reckoned equal to one duck, and ſix ducks and twelve teals are accounted a dozen of wild fowl; and the uſual market-price is about nine ſhillings for ſuch a dozen. About Midſummer, when the moulting ſeaſon is, a great number are deſtroyed alſo by the people of the neighbourhoods. The poor birds at this time are neither able to ſwim nor fly well; and the people going in with boats among the reeds, where they lie, beat them down with long poles. A little before Michaelmas, vaſt flights of theſe birds arrive at the decoys from other places; they ſoon grow fat in them, and continue there a prey to the maſters or owners, as long as the decoys are unfrozen; but when they are iced over, they fly away again, and go to the neighbouring ſeas for food. Phil. Tranſ. N° 223.

The *fens* alſo abound in a ſort of herbage that is very nourihing to cattle; ſheep and horſes always grow fat upon it. Theſe *fens* are common, and the owners of cattle mark them, that they may be known. It is remarkable, that though all is open, the cattle uſed to one particular ſpot of ground, ſeldom leave it, but the owner may find them always in or near the ſame place. The people receive great advantage from the geeſe that abound here, beſide the food which they afford; that is, from their feathers and quills; and the produce of theſe is ſo great, that the cuſtom-houſe books in the town of Boſton ſhew, that there are frequently ſent away in one year three hundred bags of feathers; each bag containing a hundred and a half weight. Each pound of feathers brings in the owner two pence; and it may be thought ſtrange by people unacquainted with theſe things, but it is a certain truth, that the owners pluck the geeſe five times a year for the FEATHERS, and once for their quills. Each plucking affords about a pound; and many people have a thouſand geeſe at a time, or more. They are kept at no charge, except in deep ſnowy weather, when they are obliged to feed them with corn.

Oats alſo grow well in many of the *fen* countries, and in good ſeaſons bring increaſe and great advantage to the owner. There is alſo another vegetable of great profit to them: this is the *rapum ſylveſtre*, the ſeeds of this they call cole-ſeed; and they make an oil from it, of great uſe in trade. They grind the ſeed between two large ſtones, the one ſtanding perpendicularly on the other. The ſtones are made of a ſort of black marble, and are brought from Germany. They ſometimes turn them by ſails, and ſometimes by the drains which carry off the water from the *fen* lands.

The *fens* lying low, and being of a vaſt extent, are very ſubject to be overflowed by waters from the neighbouring high countries; and though great care and expence are uſed to keep them dry, they are often like a ſea, and the ſheep are obliged to be carried off in boats, and people to live in their upper rooms, and be ſupplied with proviſions alſo by boats. See BOAT and DRAIN.

FEN-*cricket*. See *Mole*-CRICKET.

FEN is alſo the name of a very pernicious diſtemper to which hops are ſubject. It conſiſts of moſs or mould, which ſpreads itſelf with great rapidity, and does great damage in the hop-grounds.

FENCE, in *Agriculture*, is a hedge, ditch, wall, or bank, made round fields, woods, gardens, &c. The incloſures of grounds are in ſome places made by ditches full of water, and in others by walls either of ſtones alone, or of ſtones and earth. Where theſe materials are in plenty, they make very good *fences*, but in other places the common method is by quick-hedges. See EARTH-*bank*, HEDGE, and WALL.

Fences for parks, and ſometimes for gardens, are made of paling; which, if winter-falleu oak be uſed, will laſt many years; the pales ſhould be cleft thin, and the rails cut triangular, and the poſts ſhould not be placed too far aſunder. *Fences* round parks, where fallow deer are kept, ſhould be ſix feet and a [illegible] where there are red deer, the *fence* ſh[illegible] Parks are ſometimes fenced [illegible] ſtone.

The white thorn [illegible] to plant for a *fence*, being a [illegible], and laſting a long time, and making a very handſome *fence*. It will ſucceed on any ſoil [illegible] ditch and new bank are made, except it be wholly of gravel or ſand, and even in this caſe it will thrive, if there happen a rainy ſeaſon after the planting of it.

Some raiſe it by ſeeds, and others by young plants; the latter is the moſt expeditious way, for the ſeeds lie two years in the ground before they ſhoot, but they grow very faſt after two or three years. Some prepare the haws, or fruit of the white thorn, by tying them up in a hair bag, and ſoaking them all winter; after this, if they are ſown in February or March, they will come up the firſt year, and grow better than any other way.

Where fets are ſcarce, it is a good way when the underwoods are *felled*, or rather the year before, to ſow haws and ſloes in them, and they will furniſh a ſupply of young plants for hedges, without doing the woods any harm, becauſe they may be drawn before they come to be too large. The white thorn is alſo of conſiderable value in ſome ſorts of works; its root becomes very beautifully veined when old, and elegant boxes and combs are made of it. It is uſed by ſome alſo in the buſineſs of inlaying, and would be more ſo, if its beauty were more known. The crab and the ſloe-tree, or black thorn, come next in value to the white thorn, for quicks for *fences*.

The crabs are to be ſown by kernels, pulp and all, and they will come up the firſt year; and a ſet of young crabs planted thick enough, make an excellent *fence*. The black thorn is not ſo much approved, becauſe it is not ſo ſure of growing, and if it does, its roots ſpread, and it is apt to run in too much upon the land. The buſhes of black thorn are however the beſt of any for dead hedges, and for mending of gaps; and they have another advantage over the white thorn, which is, that cattle are not ſo apt to crop them. The black thorn will grow on any ſoil where the white grows, but the richer the mould is, the better it will thrive.

Holly is another excellent ſhrub for a *fence*; it is indeed much the beſt of all the *fence* buſhes; but it grows ſo ſlow, and is ſo uncertain, that the farmers are afraid of waiting for it, or of truſting to it; but where it ſucceeds, it makes amends for the delay in its thickneſs, height, and ſtrength. It is to be raiſed like the white thorn, either by ſets or berries, and the berries in the ſame manner lie two years in the ground before they come up. It will grow on any ſoil, even on the driеſt gravel, or among ſtones and rocks. It delights moſt in light grounds. If it be raiſed in plants, they ſhould be about the thickneſs of a man's thumb, and planted in a moiſt ſeaſon, either in ſpring or autumn; they muſt be

ſtraded well with ſtraw or haulm after they are ſet, and muſt be carefully watered, as ſoon as they begin to ſhoot, otherwiſe they will all periſh.

If any of them ſeem to periſh, they muſt be cut off cloſe at the roots, and they will often ſprout out vigorouſly thence again. The ground muſt be dug up all about them at times, which very greatly promotes their growth; and the farmer muſt keep his ſheep from them, for they are very fond of cropping the young ſprouts.

Field mice are apt to gnaw the roots of holly in hard winters; and many of theſe trees are ſuppoſed to be killed by the *froſt*, when the teeth of theſe little vermin have really done the miſchief.

The beſt way of raiſing a *fence* of theſe trees, is to plant them with the quick or white thorn, four plants of that to one of holly; theſe will thrive very well together; and while the white thorn grows very ſpeedily, the holly will take its time: as this grows large, the white thorn may be pulled up by degrees, till at length there is only the holly left; and if this is found not thick enough, the boughs of it which grow neareſt the ground may be laid down and covered with earth, and they will ſend up innumerable ſuckers, which will fill up all the gaps.

Beſide theſe there are very good *fences* made of furze, of alder and even of elder, in ſome places, on proper ſoils. Elder ſticks, or truncheons, ten or twelve feet long, are to be cut and ſtuck in the bank ſlope-wiſe each way, ſo as to make a chequer-work. This makes the ſpeedieſt ſhelter of any. When the trees grow old they are alſo ſtill of value; their wood is a very fine one for turning, and is at leaſt equal to box, if not ſurpaſſing it. The elder-tree makes an extremely good fence in watery places; and when planted on the banks of rivers is of great uſe in preventing them from being undermined by the current; the roots being very numerous, ſtrong, and compact. It is always ſending ſuckers alſo from its loweſt roots, which makes it very uſeful where ſtreams wear away their banks, and are widening their courſe.

The furze buſh, though an irregular grower, makes an excellent *fence* on dry banks where nothing elſe will grow. It may be raiſed either by ſeeds, or by ſets; but the ſeeds are the beſt, eſpecially thoſe of the French furze, which grows to the height of fifteen or ſixteen feet, and is not ſubject to ſpread with its roots, and get into the good ground, as our common heath furze will always do. This has the advantage of being a very ſpeedy grower. It will make a very good hedge in three years, if taken care of. It muſt be kept well weeded while young; and the ſheep muſt be kept away from it; for they are very fond of its young ſhoots. But it only requires this care for a little while; for when grown up to any conſiderable height, nothing can hurt it. If a furze-hedge be clipped, it will grow large and thick; but if left to itſelf, it will run up to a conſiderable height, and afford good ſhelter, and yield an excellent fuel. They ſow much of the poor land in Devonſhire with furze, and make a very conſiderable advantage of it. Miller's Gard. Dict. and Mortimer's Huſbandry.

Fences made with horn-beam plant are very common in Germany. On a parapet of earth, with a ditch on each ſide, the horn-beam ſets are planted in ſuch a manner, that every two plants may be brought to interſect one another, in the form of St. Andrew's croſs. The bark is ſcraped off in the place where they interſect, and they are bound together with ſtraw; the two plants unite together in a kind of indiſſoluble knot, and puſh from thence horizontal ſtanting ſhoots, which form a ſort of paliſado, or CHEVAUX *de friſe*. Hedges of this kind, pruned annually, will, in a few years, render the *fence* impenetrable in every part.

FENCE-*month* (*menſis prohibitionis*, or *menſis veſtitus*) is a month wherein the female deer fawn: for which reaſon it is unlawful to hunt in the foreſt during that time.

It begins fifteen days before Midſummer, and ends fifteen days after; being in all thirty days.

There are alſo certain *fence* or *defence* months, or ſeaſons for fiſh, as well as wild beaſts; as appears by ſtat. Weſtm. 2. cap. 13. in theſe words:

"All waters, where ſalmons are taken, ſhall be in *de-*
"*fence* for taking of ſalmon, from the nativity of our
"Lady, unto St. Martin's day. And likewiſe, young
"ſalmons ſhall not be taken or deſtroyed by nets, &c.
"from the midſt of April, to the nativity of St. John
"Baptiſt," &c.

FENCING, the art of defence; or of uſing the ſword, to wound an enemy, and preſerve one's ſelf from his attacks.

Fencing is one of the exerciſes learnt in the academies, &c.

The art of *fencing* is acquired by practiſing with FOILS, called in Latin *rudes*, whence *fencing* is alſo denominated *gladiatura rudiaria*.

Pyrard aſſures us, that the art of *fencing* is ſo highly eſteemed in the Eaſt Indies, that none but princes and noblemen are allowed to teach it. Theſe maſters wear a badge or cognizance on their right arms, called in their language *riara*, which is put on with great ceremony, like the badges of our orders of knighthood, by the kings themſelves.

Montaigne informs us, that when he was a youth, the nobility all ſhunned the reputation of being good *fencers*; as ſomething too ſubtle, and deſigning, and apt to corrupt virtuous manners.

Fencing is divided into two parts, *ſimple* and *compound*.

Simple is that performed directly and nimbly, on the ſame line: and is either *offenſive*, or *defenſive*. The principal object of the firſt is whatever may be attempted, in puſhing, or making paſſes, from this or that point, to the moſt uncovered part of the enemy. The ſecond conſiſts in parrying, and repelling the thruſts aimed by the enemy.

The *compound*, on the offenſive ſide, includes all the poſſible arts and inventions to deceive the enemy, and make him leave that part we have a deſign on, bare and unguarded, upon finding we cannot come at it by force, nor by the agility of the ſimple play.

The principal means hereof are FEINTS, appeals, or appels, which conſiſt in a ſudden beat of your blade on the contrary ſide to that on which you join your adverſary, and a quick diſengagement to that ſide again, claſhings, and entanglings of the ſwords, half thruſts, &c. and in the defenſive, to puſh in PARRYING.

The proper attitude in *fencing* is to hold the head upright, though the body hath an inclination forward on a longe, and all the weight reſts on the left haunch when on GUARD. The feet, hand, body, arm, and ſword, muſt be to the line. For an explication of other terms in this art, ſee the articles BEAT, CAVEATING, FLANCONADE, GLIZADE, LOCK, LUNGE, THRUST, &c.

FEND, in the *Sea Language* imports the ſame as *defend*.

Hence the phraſe *fending the boat*, &c. that is, having it from being daſhed againſt the rocks, ſhore, or ſhip's ſide. Hence alſo

FENDERS, any pieces of old cable-ropes, or billets of wood, &c. hung over the ſhip's ſide, to *fend* or keep other ſhips from rubbing againſt her; or to prevent her from ſtriking or rubbing againſt a wharf or quay.

FENDER-*bolts*. See BOLTS.

FENDUE *en pal*, in *Heraldry*, a French phraſe, applied to a croſs, to denote it cloven down from top to bottom and the parts ſet at ſome diſtance from one another.

FENESTRA, in *Anatomy*, a name applied to two holes, or apertures, in the inner EAR.

The *feneſtræ* are two openings in the labyrinth; the firſt of them is incloſed by the baſis of the *ſtapes*, and from its oval figure denominated *feneſtra ovalis*.

The latter, called *rotunda*, is cloſed with a tranſverſe tranſparent membrane, placed a little within the ſurface of its aperture.

Theſe *feneſtræ*, with the whole labyrinth, are comprehended in that part of the *os temporum*, properly called from its hardneſs *petroſum*.

FENGELD, in our *Ancient Writers*, is uſed for a tax or impoſition raiſed for repelling of enemies.

It comes from the Saxon *feind*, an *enemy*, and *geld*, *money*.

FENNEL, *Fœniculum*, in *Botany*. Linnæus has joined this genus to *anethum*. See DILL. Its characters are theſe: it hath an umbellated flower; the great umbel is compoſed of many ſmaller, which have no involucrum; the flowers have five incurved petals, and five ſtamina, terminated by roundiſh ſummits; the germen is ſituated under the flower ſupporting two ſmall ſtyles, crowned by roundiſh ſtigmas, which afterward turns to an oblong fruit, deeply channelled, dividing into two parts, each containing a ſingle ſeed, flat on one ſide, but convex and channelled on the other. There are three ſpecies.

The common *fennel* is ſo well known, as to need no deſcription. It has a ſtrong fleſhy root, which penetrates deep into the ground, and will continue ſeveral years; it flowers in July, and the ſeeds ripen in autumn. The beſt time to ſow the ſeeds, is ſoon after they are ripe; the plants will come up in the ſpring, and require no other care than to keep them clean from weeds; and they will grow in any ſoil or ſituation. The leaves, ſeed, and root of this, are uſed in medicine; the root is one of the five opening roots, and the ſeed one of the greater carminative ſeeds. There is a ſimple water made from the leaves, and an eſſential oil from the ſeed and leaves. Miller's Gard. Dict.

The oil obtained from the leaves on the upper part of the plant is much finer, lighter, and more ſubtle, than the oil obtained from the lower leaves. The former oil ſwims on water, and the latter oil ſinks. Neumann.

There is alſo a ſtrong water or brandy, made of the ſeeds of *fennel*, called *fennel-water*. The ingredients are *fennel* ſeed, liquorice, brandy, and white wine, which are diſtilled together; and to the eſſence thereof are added ſpirit of wine, ſugar, and ſweet almonds; the whole is then ſtrained, &c.

The leaves of the ſecond ſort, called *ſweet fennel*, are very long and ſlender, growing more ſparſedly, and not ending in ſo many points as thoſe of the common ſort; the ſtalks do not riſe ſo high; the ſeeds are longer, narrower, and of a lighter colour. The ſeeds are generally imported from Germany or Italy, and are by ſome preferred to thoſe of the common ſort, as being much ſweeter. Theſe ſeeds are an uſeful ſtomachic and carminative, and are ſometimes given in powder, from a ſcruple to a dram, and ſometimes candied.

The third ſort is ſuppoſed to have been brought from the Azorian iſlands, and has been long cultivated in Italy as a ſallad herb, under the title of FINOCHIA. There are not many Engliſh palates which reliſh it; nor is it eaſy to be furniſhed with good ſeeds: thoſe which are annually brought from Italy are ſeldom good; and it is difficult to preſerve the plants through the winter in England.

The ſeeds of this ſort are narrow, crooked, and of a bright yellow colour; they have a very ſtrong ſmell, like aniſeed, and are very ſweet to the taſte. Miller.

As to the method of cultivating this plant, ſee FINOCHIA.

FENNEL-*flower*, or *Devil in a buſh*, *Nigella*, in *Botany*, a genus of the *polyandria pentagynia* claſs. Its characters are theſe: the flower has no empalement, but a leafy perianthium; it has five oval, obtuſe, plain petals, which ſpread open, and are contracted at their baſe, and eight very ſhort nectariums, ſituated in a circle, each having two lips, the exterior larger, the inferior biſid, plain, and convex. It has a great number of awl-ſhaped ſtamina, which are ſhorter than the petals, terminated by obtuſe, erect, compreſſed, ſummits; and in ſome five, in others ten, oblong, convex, erect germina; the germina afterward become ſo many oblong, compreſſed capſules, divided by a furrow, but connected within, filled with rough angular ſeeds. There are ſeven ſpecies.

All theſe plants may be propagated by ſowing their ſeeds upon a bed of light earth, where they are to remain. The ſeaſon for ſowing theſe ſeeds is March; in July they will produce their flowers, and their ſeeds will ripen in Auguſt, when they ſhould be gathered and dried. Miller.

The ſeed of this plant is uſed to diſſolve the viſcous matters, which, gathering in the ſinuſſes of the head, produce catarrhs. For this purpoſe infuſe a pugil of marjoram leaves in a glaſs of white wine, and add a dram of *nigella* ſeed; ſtrain the whole through a linen cloth, and ſnuff the wine ſtrongly up the noſe. For the ſame, a piſſan is made of the tops of chamomile, melilot, and *nigella* ſeeds. The eſſential oil has the ſame virtues; it is very inciſive and expectorating; the infuſion of the ſame ſeed in wine is diuretic, and provokes the menſes.

FENNEL-*flower of Crete*. See GARIDELLA.

FENNEL-*giant*, *Ferula*, in *Botany*, a genus of the *pentandria digynia* claſs. Its characters are theſe: it hath an umbellated flower, the principal umbel of which is compoſed of ſeveral ſmaller, called rays; the involucrum is compoſed of ſeveral narrow leaves, which fall off; the principal umbel is uniform. The flowers have five oblong petals, and five ſtamina of the ſame length, terminated by ſingle ſummits. Under the flower is ſituated a turbinated germen, ſupporting two reflexed ſtyles, crowned by obtuſe ſtigmas, which afterward becomes an elliptical, compreſſed, plain fruit, dividing in two parts, each having a large elliptical plain ſeed, marked with three lines on each ſide. Linnæus reckons nine, and Miller eight ſpecies.

The parts in uſe are the medullary ſubſtance of the ſtalks, the ſeed, and the juice, or gum, which is the SAGAPENUM of the ſhops. Mr. Ray ſays, that the people of Sicily uſe the pith of the *ferula major*, or Pliny's female *fennel-giant*, for tinder to light their fires; and if this was practiſed by the ancients, we may gueſs why the poets feigned, that Prometheus ſtole fire from heaven, and carried it to the earth in a hollow *ferula*.

FENNEL, *hog's*, or *Sulphur-wort*, *Peucedanum*, in *Botany*, a genus of the *pentandria digynia* claſs. Its characters are theſe: it hath an umbelliferous flower; the cover of the large umbel compoſed of many linear reflexed leaves; the empalement of the flower is ſmall, and indented in five parts, and the petals of the great umbel are uniform. Each flower is compoſed of five oblong incurved petals, which are equal and entire; they have each five hair-like ſtamina, terminated by ſingle ſummits, with an oblong germen ſituated under the flower, ſupporting two ſmall ſtyles, crowned by obtuſe ſtigmas; the germen turns to an oval channelled fruit, ſplitting in two parts, containing two ſeeds, convex on one ſide, compreſſed on the other; with three raiſed ſorrows, and a broad membranaceous border indented at the top. Linnæus enumerates five, and Miller four ſpecies.

The common *hog's fennel* is found in wet and mooriſh places, and about ſen ditches. It flowers in June and July. Its root is eſteemed of great uſe, as an expectorant and attenuant. It is preſcribed in diſeaſes of the breaſts and lungs, particularly in thoſe in which thoſe parts are loaded with a tough phlegm. It is alſo recommended in all obſtructions of the viſcera. It promotes urine, and is recommended in nephritic caſes. The old authors have ſpoke greatly of its efficacy in all nervous caſes, and have recommended it as a ſingular remedy in lethargies, palſies, epilepſies, and the like.

If the roots are wounded, when freſh, in the ſpring or autumn, they yield a yellow juice, which dries into a ſolid gummy reſin, that is recommended as an aperient and antihyſteric. Lewis's Mat. Med.

FENNEL, *ſcorching* in *Botany*. See THAPSIA.

FENNEL, *ſea*. See SAMPHIRE.

FENUGREEK, *Fœnum Græcum*, *Trigonella*, in *Botany*, a genus of the *diadelphia decandria* claſs. Its characters are theſe: the empalement of the flower is well ſhaped, of one leaf, cut at the top into five almoſt equal ſegments; the flower is of the buttertly kind; the ſtandard obtuſe, oval, and reflexed; the two wings are oblong, reflexed, and ſpreading flat like the ſtandard, ſo as outwardly to appear like a regular flower of three petals; the keel is very ſhort, obtuſe, and occupies the navel of the flower; it hath ten ſhort riſing ſtamina, nine of which are joined, and one ſtands ſeparate, terminated by ſingle ſummits; and an oval, oblong germen, ſupporting a ſingle ſtyle, crowned by a riſing ſtigma; the germen afterward turns to an oblong oval pod, compreſſed, filled with kidney-ſhaped ſeeds. Linnæus enumerates ten, and Miller ſix ſpecies.

The firſt ſort is the common *fenugreek*, whoſe ſeed is uſed in medicine. Where this plant grows naturally is uncertain; but it is cultivated in the ſouth of France and in Germany; from whence great quantities of the ſeed are annually imported here for uſe. It is alſo much cultivated in India.

This plant has not yet been cultivated in any quantity for uſe in England, as it has generally proved a very uncertain crop, occaſioned by the inconſtancy of the weather. The ſeed from the continent is therefore always to be preferred. Miller.

The ſeeds of this plant contain an expreſſible oil blended with reſin and mucilage, but no eſſential oil; to rectified ſpirit they communicate the whole of their diſtinguiſhing ſmell and taſte; and afterwards to water a ſtrong ſavourleſs mucilage. The principal uſe of theſe ſeeds is in cataplaſms and fomentations, for ſoftening, maturating, and diſcuſſing tumors; and in emollient, carminative clyſters. They are an ingredient in the *decoct è mucilaginibus* of the ſhops. Ground in a mill, they are uſed in drinks for horſes. Neumann and Lewis.

The ſeed is leſs than muſtard-ſeed, very hard and ſolid, of a triangular form, and a ſtrong diſagreeable ſmell, when new, it is of a yellow gold-colour, but when long kept, ruddy, or brown.

FEODAL, *Feodalis*, or *Feudalis*, of or belonging to a *feud*, or FEE. Hence *feudal* ſervices, &c.

FEODALITY, the REALTY paid to the lord by his feudal tenant.

FEODARY, *Feudary*, or *Feudatory*, an officer anciently made and authorized by the maſter of the courts of wards. 32 Hen. VIII. cap. 26.

His office was to be preſent with the eſcheator, at the finding any office of lands; and to give evidence for the king, concerning the tenure, and the value thereof; to ſurvey the land of the ward after the office found, and rate it. He alſo aſſigned the kings widows their dowers, and received the rents of wards lands. This office is taken away by ſtat. 12 Car. II. cap. 24.

FEODATARY, or FEUDATARY. See FEODARY and FEUDATARY.

FEODER, a MEASURE for liquids, uſed throughout Germany.

FEODITAS, in *Old Writers*, is ſometimes uſed for *fidelitas*, or REALTY.

FEODUM, or FEUDUM, the ſame with *fief* or FEE.

FEOFFMENT, derived from the verb *feoffare*, or *infeudare*, *to enfeoff*, *to give one a feud*, in *Common Law*, is the moſt ancient method of conveyance, and ſignifies a gift or grant of honours, caſtles, manors, meſſuages, lands, or the like corporeal or immoveable things, to another in fee-ſimple; that is, to him, and his heirs for ever, by the delivery of ſeiſin, and the poſſeſſion of the thing given. See FEE, and LIVERY.

When this is done by writing, it is called the *deed of feoffment*.

In every *feoffment*, the giver is called the *feoffer*, or *feoffator*, and he that receives, the *feoffee*.

The proper difference in our law, between a *feoffer*, and a donor, is, that the *feoffer* gives in fee-simple; and the donor in fee-tail.

FERÆ, in the Linnæan syſtem of *Zoology*, one of the orders of animals, of the claſs of *mammalia*; the characters of which are, that they have ſharp teeth; the upper fore-teeth are ſix in number, and the canine or dog-teeth longer than the reſt. Of this order are the bear, the lion, the tyger, the cat, the weaſel, the ferret, the didelphis or philander, the otter, the ſea-calf, the dog, the badger, the hedge-hog, the mole, and the bat, which this author makes not a bird, but a quadruped, with its fore-feet expanded into a ſort of wings, &c.

FERÆ *naturæ*, in our *Law*, ſignify birds or beaſts that are wild, in oppoſition to ſuch as are tame: ſuch are hares, foxes, wild geeſe, or the like, wherein no man may claim a property. 2 Cro. 293.

FERALIA, *in Antiquity*, a feaſt held by the Romans, on the twenty-firſt of February, in honour of the dead. Vide Mem. Acad. Inſcript. tom. i. p. 43.

Varro derives the word from *infera*, or from *fera*; on account of a repaſt carried to the ſepulchres of ſuch as the laſt offices were that day rendered to. Feſtus derives it from *ferio*, on account of the victims ſacrificed. Voſſius obſerves, that the Romans called death, *fera*, *cruel*, and that the word *feralia* might ariſe thence.

Macrobius, Saturn. lib. i. cap. 13. refers the origin of the ceremony to Numa Pompilius. Ovid, in his Faſti, goes back as far as Æneas for its inſtitution. He adds, that on the ſame day a ſacrifice was performed to the goddeſs Muta, or *Dumb*; and that the perſons who officiated, were an old woman, attended with a number of young girls.

FER *de fourchette, croix à fer de fourchette*, in *Heraldry*, is a croſs, having a forked iron at each end, like that formerly uſed by ſoldiers to reſt their muſkets on; by which it is diſtinguiſhed from the croſs *fourché*; the ends whereof turn forked; whereas in this, the fork is fixed on the ſquare ends; as repreſented in *Tab. Heraldry, fig.* 20.

FER *de moulin*, q. d. *iron of the mill*, is a bearing in *Heraldry*, ſuppoſed to repreſent the iron ink, or ink of a mill, which ſuſtains the moving mill-ſtone. See a repreſentation of it in *Tab. Herald. fig.* 21.

FERD-*wite*, or FERD-*wite*, in our *Ancient Cuſtoms*, a formulary, by which the king pardoned manſlaughter, committed in the army.

The word is formed of the Saxon *ferd*, *army*, and *wite*, *puniſhment*.

FERDFARE, from the Saxon *ferd*, *army*, and *fare*, *journey*, in our *Old Writers*, is uſed for being diſcharged from going to war.

FERENTARII, or FERENDARII, among the Romans, were auxiliary troops, lightly armed; their weapons being a ſword, bow, and arrows, and a ſling; which were much leſs cumberſome than a buckler, battle-ax, pike, &c.

The name ſeems to have been derived *a ferendo auxilio*; theſe being auxiliary forces; though Varro thinks they might be ſo called, becauſe the ſling and ſtones *feruntur, non tenentur*.

We have alſo mention of another ſort of *ferentarii*, whoſe buſineſs was, to carry arms after the armies, and to be ready to ſupply the ſoldiers therewith in battle.

Lydius uſes the name *ferentarii* for the *cataphractis equites*, i. e. cavaliers, armed cap-à-pe.

FERETRUM, among the Romans, the bier uſed in carrying out the bodies of the dead; which duty was performed by the neareſt male relations of the deceaſed: thus ſons carried out their parents, brothers their ſiſters, &c. See BURIAL.

FERIÆ, among the Romans, were holy-days, or days wherein they abſtained from work.

The word *feriæ* is uſually derived *a ferendis victimis*, on account of the victims killed on theſe days. Martinius ſays, that *feriæ* were ſo called *veluti locus quæpiam, dies ſacri, holy days*. Others obſerve, that all days in general, though they were not feaſt-days, were anciently called *feſtæ*, or, as Voſſius reads it, *feſiæ*; whence, according to that author, was formed the word *feriæ*.

The *feriæ*, or *dies ferati*, were obſerved and diſtinguiſhed chiefly by reſt; whereas the *feſti*, or *dies feſti*, beſide a ceſſation from labour, were celebrated with ſacrifices and games; ſo that there were *feriæ*, which were not feaſt-days; though authors frequently confound the *feriæ*, and *feſti*.

Others confound the *feriæ* with the *dies nefaſti*, or *non-court-days*.

The Latin *feria* amounts to the Sabbath of the Hebrews.

The Romans had divers kinds of *feriæ*; their names, at leaſt the principal thereof, are *æſtivales*, or ſummer *feriæ*; *annuæ feriæ*, yearly *feriæ*; *compitalitiæ feriæ*, of the ſtreets and croſs-ways; *conceptivæ*, votive *feriæ*, which the magiſtrates promiſed every year; *denicales*, for the expiation of a family polluted by the death of any one; *imperativæ*, or *indictivæ*, thoſe decreed by the magiſtrate; *Latinæ*, the Latin *feriæ*, inſtituted by Tarquin the Proud, for all the Latin people, amounting annually, ſays Dion. Hal. to forty-ſeven nations, being celebrated on mount Alba, in memory of the peace concluded by Tarquin with the people of Latium. Theſe *feriæ Latinæ* were either ordinary or extraordinary. They continued at firſt only for a day; but after the expulſion of Tarquin, a ſecond day was added, and a third after the reconciliation between the plebeians and patricians; and in proceſs of time they were prolonged to four days. At theſe feaſts a bull was ſacrificed, and each town contributed a certain quantity of meat, wine, and fruits. *Meſſiæ feriæ* were thoſe of harveſt; there were alſo *paganales feriæ*, or PAGANALIA; *præcidaneæ*, which were what we properly call the vigils, or eves of the feaſts; *privatæ*, or *propriæ*, thoſe peculiar to the ſeveral families; as the *familiæ Claudiæ, Æmiliæ, Juliæ*, &c. *publicæ*, thoſe obſerved by all in general, or for the public weal; *ſementinæ*, thoſe held in ſeed-time; *ſtativæ*, thoſe kept conſtantly to the ſame day of the year; *Saturnales*, whereof we ſhall ſpeak in their place; *ſtultorum feriæ*, or *quiritalia*, the *feriæ* of fools, held on the ſeventeenth of February; *victoriæ feriæ*, thoſe of victory, in the month of Auguſt; *vindemiales*, thoſe of the vintage, from the twentieth of Auguſt to the fifteenth of October; *Vulcani feriæ*, thoſe of Vulcan, which fell on the twenty-ſecond of May. See FEAST.

FERIÆ was alſo uſed among the Romans for faſt-days; becauſe it was their cuſtom to hold their faſts on the *dies feriati*, or holidays. Struv. Synt. Antiq. Rom. cap. ix. p. 425. 443, &c.

FERIA is ſtill retained in the Romiſh breviary, though in a ſenſe ſomewhat different from the *feriæ* of the ancients; being applied to the ſeveral days of the week, beginning with Sunday; provided none of thoſe days be a feaſt or faſt-day. Thus, Monday is the ſecond *feria*; Tueſday the third, &c.

The word *feriæ* in this ſenſe, is doubtleſs borrowed from the ancient *feriæ*, a day of reſt. Accordingly, Sunday is the firſt *feria*; for anciently all the days of Eaſter-week were accounted feſtival days, by a decree of Conſtantine; whence thoſe ſeven days were called *feriæ*; Sunday being the firſt, Monday the ſecond, &c. And this week being then accounted the firſt of the eccleſiaſtical year, they afterwards accuſtomed themſelves to call the days of the other weeks after the ſame manner, *firſt, ſecond, third*, &c. *feriæ*. Though others will have it, that the days of the week were not called *feriæ* from the people's reſting, that is, on account of being obliged to abſtain from ſervile works; but to advertiſe the faithful, that they ought to abſtain from ſin. See Durand, De Off. Div. lib. viii. cap. 1.

Theſe are the *ordinary feriæ*; but beſides theſe, they have *extraordinary*, or *greater feriæ*; viz. the three laſt days of Paſſion-week; the two days following Eaſter-day, and Whitſunday; and the ſecond *feriæ* of Rogation.

FERIAL *days*, *dies* FERIALES, or FERIÆ, among the *Ancients*, ſignify holidays, or days vacant for labour, and pleading.

But in the ſtat. 27 Hen. VI. cap. 5. and in Forteſcue, De Laudibus LL. Angliæ, *feriæ* days are taken for working days. S. Sylveſter ordained—*Sabbati & dominici dies nomine exiſtit, reliquos hebdomadæ dies feriarum nomine diſtinctos, ut jam ante in eccleſia vocari cæperant, appellari*.

So that *feriæ* days are properly all the days of the week, except Sunday.

FERIJEE, in the dreſs of the Egyptians, is a ſort of ſkirt worn over another garment, and made either of black woollen, or of other coloured cloth furred; this by the more genteel people is left open before. It ſomewhat reſembles a night-gown.

FERISON, in *Logic*, a mood of the third figure of ſyllogiſms. In this mood the firſt propoſition is an univerſal negative, denoted by the vowel *e*; the ſecond a particular affirmative; and the third a particular negative. Signified by *i* and *o*.

FERLING, in our *Old Statutes*, is uſed for the fourth part of a penny. *Aſſiſ. panis & cervefi*, 51 Hen. III.

FERLINGATA *terræ*, in our *Old Writers*, according to Blount, is the ſame as *ferlingus terræ*, which lord Coke on Littleton ſays, was a quarentine, or thirty-two acres of land. But according to the authorities quoted by Du-Cange, Gloſſ. Lat. voc. *Quarentena*, it contained but forty perches.

FERLINGUS *terræ*. See FERLINGATA *terræ*.

FERM,

FERM, FIRMA, in *Law*. See FARM.

FERME *à ferme*, in the *Manege*, fignifies to exercife in the fame place without ſtirring or parting.

FERMENT, of *fervere*, *to boil*, in *Phyſics*, any body, which being applied to another, produces a *fermentation* therein; or, any thing capable of exciting an inteſtine motion in the parts of another; and of ſwelling or dilating the ſame.

Thus, the acid in leaven is a *ferment*, which makes bread riſe or ſwell. And the moiſture in hay is a *ferment*, which heats, and makes it ſmoke. Thus alſo, rennet is a *ferment*, which curdles and breaks milk; and barm, or yeaſt, is the *ferment* that ſets wort a working, &c.

Thoſe things are called *ferments* in an allufive ſenſe, which when added to the liquor, only correct ſome fault therein, and by removing ſome obſtacle to the *fermentation*, forward it by ſecondary means; as alſo ſuch as being added in time of *fermentation*, make the liquor yield a larger proportion of ſpirit, and give it a finer flavour; all theſe additions have the name of *ferments* among our diſtillers, but improperly. The primary uſe of *ferments* is, to ſave time, and make diſpatch of buſineſs, while they only occaſionally and accidentally give a flavour, or add to the quantity of the ſpirit; and accordingly all *fermentable* liquors may, without the leaſt addition, only by a due application of heat, be brought to *ferment* more perfectly, though it will be more ſlowly than with the addition of any *ferment*. The general *ferments* uſed on theſe occaſions are the flowers and *faces* of *fermentable* liquors generated, thrown up, or depoſited, during the time of the *fermentation* in that liquor, or after the end of it. Theſe are two of theſe *ferments*, procurable in large quantities, and at a ſmall price; theſe are beer yeaſt, and wine lees. A prudent and artificial management of theſe, might render the buſineſs of the brewery for diſtillation, as in the buſineſs of the malt-diſtiller, &c. much more eaſy and advantageous. It has always been found a great difficulty to procure theſe *ferments* in proper quantities, and preſerve them always ready for uſe; and this has been a great diſcouragement to the buſineſs, and hence ſome have been obliged to contrive artificial *ferments*, or to form mixtures or compounds of particular *fermentable* ingredients; but this has been attempted without any great ſucceſs, all theſe mixtures falling ſhort even of the common baker's leaven in their uſe.

When the proper ſort of *ferment* is pitched upon, the operator is next to conſider its quantity, quality, and manner of application. The quantity muſt be proportioned to that of the liquor, to its tenacity, and the degree of flavour it is intended to give, and to the diſpatch required in the operation. From theſe conſiderations he will be able to form a rule to himſelf; but till ſuch a rule is formed, or, in order to forming it, proper trial will ſhew how much ſuffices for the purpoſe. The way is to begin with a little, and to add more occaſionally, the weight of the whole being noted beforehand; ſo that on weighing the remainder after the proper quantity is taken away, it will be found how much exactly has been uſed out of it for the buſineſs.

Among the ſeveral ingredients of which *fermentable* liquors are made for the ſervice of the diſtillery, treacle requires more *ferment* than almoſt any other. This is not wonderful on a juſt conſideration of the nature of the ſubject, ſince the manner in which that concrete juice is made, muſt render it greatly unfit for *fermentation* afterwards, though the original product of a vegetable juice very much diſpoſed to it in its own nature. The ſtrength of the fire uſed in the ſugar making, and its long continuance and almoſt immediate contact, and the lime and other alkalies uſed in refining the ſugar, that is, in making the treacle, do ſo conſenſe, indurate, and ſcorch the body of this juice, and abſorb its acid, that it is ſcarce to be expected that it ſhould *ferment* at all, even with the addition of julap, or other powerful ſaline and acid or acrid ſtimulators, which tend to break the viſcous and adult connections of the particles.

The greateſt circumſpection and care are neceſſary in regard to the quality of the *ferment*, if a pure and well flavoured ſpirit be required. It muſt be choſen perfectly ſweet and freſh, for all *ferments* are liable to grow muſty and corrupt; and if in this ſtate they are mixed with the *fermentable* liquor, they will communicate their naſtiouſ and filthy flavour to the ſpirit, which will ſcarce ever be got off by any ſubſequent refining. If the *ferment* be ſour, or muſt by no means be uſed with any liquor, for it will communicate its flavour to the whole, and even prevent its riſing to a head, and give it an acetous, inſtead of a vinous tendency. When the proper quantity of a ſuitable and well conditioned *ferment* is got ready, it muſt be put to the *fermentable* liquor in a ſtate barely tepid, or ſcarce lukewarm. The beſt manner of putting them together, ſo as to make the *fermentation* ſtrong and quick, is this. When the *ferment* is ſolid, it muſt be broke to pieces, and gently thinned with ſome of the warm liquor; but a complete or uniform ſolution of it is not to be expected or deſired, as this would weaken its efficacy for the future buſineſs. The whole intended quantity being thus looſely mixed in ſome of the lukewarm liquor, and kept near the fire, or elſewhere, in a tepid ſtate, free from too rude commerce of the external air, more of the inſenſibly warm liquor ought at proper intervals to be brought in, till thus by degrees the whole quantity is ſet at work together.

When the whole is thus ſet at work, and ſecured in a proper degree of warmth, and kept from a too free intercourſe with the external air, it becomes as it were the ſole buſineſs of nature to finiſh the operation, and render the liquor fit for the ſtill. In this eaſy manner the whole end of *fermentation* would be anſwered. But during the whole courſe of the operation, there are ſeveral other things that may be added with ſome particular view, as either to increaſe the quantity of ſpirit, or give it ſome agreeable flavour. Theſe ADDITIONS may ſometimes require ſome alteration in the general method laid down above, though upon the whole it is right. Shaw's Eſſay on Diſtilling.

The force or effect of a *ferment* ariſes hence, that, by its more penetrative and moveable parts, it diſſolves and breaks the texture or combination of the component parts or principles of the body, gives them a new motion, and diſpoſes them to take a new arrangement, or to combine again in a new manner; and ſo to conſtitute a new ſpecies of body.

Thus the bite of a mad dog excites a ſlow *fermentation* in the blood, whereby the divers liquors, or matters it conſiſts of, loſe that nexus, or union, neceſſary to a ſtate of health; and occaſion an irregularity in the ſpirits, from which ariſe the horrors, and other ſymptoms of the diſeaſe.

One way of accounting for DIGESTION, is by ſuppoſing a certain *ferment* in the ſtomach. But what this *ferment* is, or whence it ſhould be derived, is greatly diſputed.

FERMENTS *in the earth*. It is very probable, that the natural *ferments* in the earth may be of more conſequence than is generally ſuppoſed, and tend to elucidate many things, which at preſent appear very myſterious. The different fruitfulneſs of different ſpots of the ſame ſort of land may be owing to this, as alſo the different temperature of air at the ſame time in places very little diſtant from one another. The effluvia ſent up by ſome of theſe, not only diſſolve ſnow that falls on them, but even melt it in the air as it approaches, and cauſe it to fall in rain, not in ſnow. And often in two places within a mile or two of each other, there ſhall be a diſparity of heat and cold no way eaſy to be accounted for, ſince there is often no difference of ſhade or ſhelter.

In Scotland there are large tracts of land, where the *ferment* is ſo ſtrong, that the earth lets a perſon up to the ankles as he walks; and generally, at about a foot depth under this, there is found a ſtratum of pebbles, ſo cloſe rammed together, that they ſeem an artificial cauſeway. This land, though of no greater depth than a foot, is found very rich for garden plants, and even for fruit-trees. Phil. Tranſ. N° 110.

FERMENT, among *Phyſicians*, is ſometimes uſed in a ſynonymous ſenſe with putrefaction, or rather for a putrid habit of body, conſidered as the cauſe of malignant diſorders.

But theſe authors are, nevertheleſs, very careful not to confound putrefaction with vegetable *fermentation*, accounting them only analogous proceſſes; for which reaſon, they uſe the ſame term for the putrefying and fermenting agent. It were to be wiſhed, to avoid ambiguity, that we had two different words to denote the exiſting cauſe of theſe two inteſtine commotions; but this is the leſs to be expected on account of the tendency of all putrid animal ſubſtances to promote both animal putrefaction, and a vinous *fermentation* in vegetables.

FERMENTARII, or FERMENTACI, a denomination which thoſe of the Latin church have given to the Greeks, on account of their conſecrating and uſing leavened or *fermented* bread in the euchariſt.

As the Greeks call the Latins *azymites*, the Latins, in return, call them *fermentarii*.

FERMENTATION, an inteſtine motion, ariſing ſpontaneouſly among the ſmall, inſenſible particles of a mixed body, and producing a new diſpoſition, and a different combination of thoſe parts.

Fermentation differs from diſſolution, as the latter is only a reſult, or effect of the former: *fermentation* is frequently without diſſolution, i. e. the fermentative motion ſeldom goes ſo far as to diſſolve the body; but diſſolution always ſuppoſes an antecedent *fermentation*.

Fermentation differs from ebullition and effervescence in

this, that the motion, which in the first is slow, in the two latter is violent; and that, in the first, the motion is restrained to the minute particles of the body; but in the latter, it extends to large masses thereof.

Indeed it must be observed, that authors usually allow of divers kinds of *fermentations*; viz. an insensible one, which is only known from its effects; and a sensible one; a violent and a moderate one; a hot and a cold one; a natural and an artificial one.

Chemists distinguish three particular kinds of *fermentation*, or three stages of the same *fermentation*, which refer to the three principal products resulting from it. The first is called the *vinous* or *spirituous*, because it changes into WINE the liquors which undergo it, and because from this wine may be obtained an inflammable spirit, miscible with water, called spirit of wine. The second kind of *fermentation* is called *acid*, or *acetous*, because the product of it is an acid or VINEGAR. The third kind is called the *putrid* or *putrefactive*, and sometimes the *alkaline fermentation*, in which case the texture of the fermented substance is destroyed, and having lost its original characters of taste, colour, and smell, it becomes foetid, rotten, and offensive; and if committed to distillation, yields neither an inflammable nor an acid spirit, but a sharp pungent liquor, being a solution of volatile alkaline salt, nearly similar to that salt which may be obtained by the force of violent heat, from animal substances, without suffering them first to become putrid.

All matters susceptible of the spirituous *fermentation* may afterwards undergo the acid, and, lastly, the putrid *fermentation*; but some substances are not susceptible of the spirituous *fermentation*, but proceed first to the acid, and afterwards to the alkaline or putrid *fermentation*; and lastly, some substances are susceptible of the putrid *fermentation* only. From these considerations, and others of a similar nature, Stahl and many other chemists consider these *fermentations* less, as three operations distinct and independent of each other, than as three principal and distinguished degrees of one and the same fermentative motion, by which nature endeavours to resolve, and to reduce into a similar condition, all the moist compound bodies, into the combination of which the oily principle enters, that is, all animal and vegetable substances. These substances, as long as they make part of the living vegetable or animal, undergo *fermentation* in a slow and insensible manner, being preserved from it by the vital motion; but when the life of organized bodies ceases, all these substances sensibly acquire the fermentative motion, pass more rapidly and regularly from one stage of it to another, according to the concurrence of circumstances which generally favour *fermentation*; so that *fermentation*, in this view of it, appears, upon the whole, to be nothing else than PUTREFACTION. See DIGESTION. Dict. Chemistry, art. FERMENTATION.

Plants bruised, and left a certain time in a close vessel, ferment of themselves; and, if let alone, the *fermentation* will proceed to putrefaction.

In order to *fermentation*, it is necessary the ferment have something acid and spirituous in it; that its motion be tumultuous; that it be in an open, spacious place, and assisted by the air; and that it tend to exalt and purify the body, and produce vinous, or inflammable spirits. These are the particular properties and conditions of *fermentation*; though, in the general, all required to effect a *fermentation*, in a body, or liquor, which is not homogeneous, that is, which consists of different principles, is, that there be a strong attraction between the particles of the ferment, and the body; that the parts of this latter be moved and agitated irregularly; and that this motion produce some alteration in the mixed.

All vegetable and animal substances, into the composition of which enters a certain quantity of fluid oil and earth, rendered perfectly soluble in water, by the intervention of a saline matter, being diffused in a sufficient quantity of water to become liquid, or at least soft, and being exposed to heat from a few degrees above the freezing point to twenty-five and more, and when the communication with air is not entirely obstructed, suffer spontaneously the fermentative motion, which entirely changes the nature and proportion of their principles; and, therefore, the *fermentation* of any body may be prevented or suspended by intense cold, want of air and water, and a disproportion of the principles of the body exposed to *fermentation*.

Fermentation is one of the most obscure processes in all nature. The generality of our later philosophers allow it in great measure a mystery, to which their principles will not fully reach. Dr. Morgan attempts to account for it, on the Newtonian system. His principle is, that the expansive force of air, rarefied by the action of fire, or the mutual action of fire and air, is the universal natural cause of *fermentation* and dissolution.

To shew this, he considers two great powers, or principles, in bodies; viz. an attractive, cohesive power, in the small particles of matter, as the principle of all rest, concretion, &c. and the expansive force of heated air as the principle of *fermentation*. On the different proportion and adjustment of these two opposite forces, with respect to each other, the constitution, texture, and cohesion of bodies, are said to depend.

By the attractive force, acting alone, the constituent parts of compound bodies must be brought to their nearest and greatest contacts, and remain there in a degree of firmness and cohesion, proportional to the quantities of contact.

On the other hand, by the repulsive, expansive force, acting alone, all bodies, even the most compact and solid, must be dissolved and diffused into one perfectly fluid incoherent mass.

If both be found in the same body, and equal in degree, such a body must continue in its present state of fluidity, or cohesion; if the attractive power prevail, the quantity of contact, or degree of cohesion, will be continually increased to a certain pitch, where it will rest. On the contrary, if the expansive force of the fire and air, included in any body, or mass of matter, prevail against the attractive power of the contiguous parts, the parts must necessarily recede from their points of contact.

And this happening through all the subdivisions of which the body or mass is capable, every small part must be divided and separated into other smaller parts; and these again into others, and so on, till we come to the first constituent particles or atoms, which are supposed to be perfectly solid, and indivisible.

This recess of the parts of bodies from their points of contact, and the separation and division consequent thereon, is what we call *rarefaction*; as, on the contrary the approach of the parts nearer to the points of contact, is called *condensation*. Now from the contrary effects of these two forces, there necessarily arises an intestine commotion, collision, and natural struggle of the parts among themselves; i. e. the parts acted on by two such opposite forces, will fly off and recoil, recede and accede, in proportion to the strength and energy of the opposite powers, till one or the other prevail, either to fix and condense, or to dissolve and diffuse it; which alternate motion is what we call *fermentation*.

If the attractive force prevail, the most fluid body will be consolidated, as water into ice.

The circumstances necessary for causing a *fermentation* between a solid and a fluid, as they are stated by Dr. Freind and Dr. Keill, the reader will find under ATTRACTION, art xvi. and MENSTRUUM.

Dr. Boerhaave makes the following conditions requisite. 1. That there be a due proportion between the size of the particles of the fluid, and the pores of the body to be dissolved. 2. That the figure of the particles of the fluid have a determinate relation to that of the pores of the solid. 3. That the particles of the fluid be sufficiently solid, so that their moment or force of action be not too weak. And, 4. That the particles of the fluid, when received into the pores of the solid, be fitly disposed to make some stay there, and not immediately to pass through; but to act every way upon the solid as they move towards the external surface thereof. Chemistry, by Shaw, p. 344.

Mr. Rowning apprehends, that nothing more is necessary, than that the particles of the solid attract those of the fluid with a greater degree of force than either those of the fluid or those of the solid attract one another; and that this single supposition will apply to the solution of a solid by a fluid, and to the *fermentation* occasioned by the mixture of two fluids. Nat. Phil. part ii. *diff.* 8.

But perhaps a more accurate and complete theory of *fermentation* may be formed by means of the modern discoveries, relating to air. Air is known to be combined with various substances, and to adhere to their constituent particles in a fixed or non-elastic state, forming, according to Dr. Hales and others, the cement or bond of union between them. This principle, which is now generally known by the name of *fixed* AIR, is supposed to be the immediate cause of COHESION, since the preservation of firmness and soundness in bodies depends on restraining the escape of this air; for as soon as it flies off, and resumes its elasticity, the other constituent particles, viz. the earthy, saline, oily, or inflammable and aqueous, being hereby put into motion, immediately begin to exert their several peculiar attractive and repulsive powers, and run into new combinations, which first change, and at length altogether destroy the texture of the substance which they formerly composed, provided that this substance contained in itself a sufficient quantity of water to allow of the intestine motion, by giving the proper degree of fluidity or moisture; for without fluidity there

can be no intestine motion, and without intestine motion there can be no change of combination. Whatever, therefore, in these circumstances, occasions a release of this air, and serves to change its state, from that of a concrete body into an elastic repelling fluid, will produce *fermentation*. It is well known, that the particles of bodies attract each other within certain distances; and that, when they are placed beyond the sphere of each other's attraction, they begin to exert a repulsive power. Heat may be one cause of expanding bodies, so that these constituent particles may be removed to such distances from each other, that their attraction shall cease, and their mutual repulsion commence. A quick vibration, and violent intestine motion excited among the minute particles of bodies, will occasion a similar separation of these particles, and a consequent change from a concrete to a repelling state. Thus, when any two united particles are torn asunder by the superior attraction or AFFINITY of a menstruum or solvent, they must at the instant of separation recede from each other with a force equal to that with which their disjunction was resisted. And the effect of the violent separations of the particles of bodies, which occur in chemical decompositions, solutions, and *fermentation*, will appear very great, when we consider the minuteness of the particles engaged in these operations, and how much the activity or force of the attraction and repulsion of bodies depends on the smallness of their size. See on this subject Macbride's Essays, ess. 2. Chemical Dict. Eng. ed. 2. vol. iii. p. 80, 81. See PUTREFACTION.

The business of *fermentation* is one of the great preparations to the distillery. What we usually call vinous *fermentation*, in particular, is the kind in which it is principally concerned. By this we usually understand that physical action, or intestine commotion of the parts of a vegetable juice, tincture, or solution, which render them fit to yield an inflammable spirit on distillation.

This *fermentation* in the hands of the distiller differs from the common one, that is used in the making of potable vinous liquors, as being much more violent, tumultuary, active, and combinatory than that. A large quantity of yeast, or other ferment, is added to the distiller's *fermentation*; the free air is admitted, and every thing is contrived to quicken the operation, so that it is sometimes finished in two or three days. This great dispatch, however necessary to the large dealer, has its inconveniencies attending it; for the spirit is by this means always fouler, more gross, and really terrestrial, than it would have been if the liquor had undergone a proper *fermentation* in a slower manner. It also suffers a diminution in its quantity, from the violent and tumultuary admission, conflict, and agitation of the free air, both in the body and upon the surface of the liquor, especially if the liquor be not immediately committed to the still as soon as the *fermentation* is fairly slacked or fully ended. It is a very difficult task to render the business of *fermentation* at once perfect and advantageous. To ferment in perfection, necessarily requires length of time, and careful attendance, and close vessels, besides several other articles of nice management, which cannot be expected to be received and practised in the large way, on account of the trouble and expence, unless it could be proved to the distillers, as possibly it may some time, that the quantity of spirit would be so much greater from the same quantity of materials managed thus, than by the common way, that it will more than pay its own expence; to which may be added, the very well known advantage of the spirit thus procured by perfect *fermentation*, being much finer than that obtained in the common way: till this shall be made out, it may not be amiss to try how much of the more perfect art of vinous *fermentation*, is profitably practicable by the distiller in the present circumstances of things. The improvements to be made in this affair will principally regard, 1. The preparation or previous disposition of the fermentable liquor. 2. The additions tending to the general, or some particular end. 3. The admission or exclusion of the air. 4. The regulation of the external heat or cold; and, 5. A suitable degree of rest at last. When proper regard is had to these particulars, the liquor will have its due course of *fermentation*, and it will thence become fit to yield a pure and copious inflammable spirit by distillation. The tincture, solution, or liquor, intended for *fermentation*, for the still, should be considerably thin and aqueous. That sort of richness there is in the twelve shilling small beer, is the utmost that ought to be allowed to it. This property not only fits it to ferment readily, but also to yield a larger quantity, in proportion, of a pure vinous spirit, than it would do if it were more rich or clammy: the gross, foul, viscid, and earthy particles of such glutinous liquors being, after *fermentation*, apt to rise up with the boiling heat which must necessarily be employed to raise the spirit; and the spirit thus of course comes over foul and fetid. There is also another disadvantage attending the thinness of this liquor, which is, that it will sooner become fine by standing before *fermentation*; whence it may be commodiously drawn off from its feces or bottom, which must always in case of corn, malt, or any other mealy substance, be kept out where the purity of the spirit is consulted. A certain degree of warmth seems necessary in all the northern climates, to all sorts of artificial liquors, intended for immediate *fermentation*, especially in winter; but the natural juices of vegetables, which have never been inspissated, as that of grapes, and other fruits, when fully ripened, will usually ferment, as soon as they are expressed, without any external assistance. But as a certain degree of inspissation prevents all tendency to *fermentation* in all vegetable juices, though otherwise strongly disposed to ferment: to a long continuance, or an increase of the inspissating heat, especially if it acts immediately through a metalline or solid body upon the juice, will destroy its fermenting property; and it will do this the more effectually, as the heat employed approaches to that of scorching, or the degree capable of giving an empyreuma. After the same manner, several experiments make it appear that there is a certain degree of heat, the continuance, or least increase of which, proves detrimental or destructive to *fermentation*; as there is another, which in a wonderful manner encourages and promotes it. These two degrees of heat ought to be carefully noted and settled by the thermometer, or other certain methods, for philosophical and chemical uses; but for common, or all œconomical occasions, they may be limited to what we call a tepid and fervid heat: a fervid heat is the lone of all vinous *fermentation*; as a tepid one, or rather an imperceptible warmth, is the great promoter of them. In this neutral state, therefore, with proper contrivances to preserve and continue it, the liquor is to be put into a suitable vessel for *fermentation*; at which time if it works not of itself, it must be quickened by additions; and, in general, by such things as are commonly called FERMENTS. See SPIRITS, MAKING up, LOWERING, &c.

The juices of plants are strongly altered by *fermentation*, and are susceptible of many and those very various, changes from it. And it is not only the juices of fruits that are thus to be wrought upon, as those of apples, pears, grapes, and the like, in the common way; but there is an artificial change to be made in the seeds of plants by what is called malting. And it is not grain alone that is thus to be wrought upon, but any other seed whatever may be made to yield its juices and virtues freely to water by this process. The juices of roots also, for instance that of liquorice, will be wrought upon in the same manner; and the juices of the bodies of trees, as of the birch, and the like. If in the month of March a hole be bored into the body of a birch-tree, and this hole be stopped with a cork, through the middle of which there is thrust a quill open at both ends, the juices of the tree will drop out at the quill at the rate of a large drop every second of a minute, and a great quantity will in time be obtained in this manner. This liquor is not unpleasant to the taste, and looks tolerably clear, resembling water into which a little milk had been spilt. There are many ways of fermenting this juice, by all of which it is converted into a sort of wine. These are well known; but there is another remarkable property in our maples, both the common small kind, and the great one, which we call the sycamore; these being tapped in the same manner, will bleed freely in winter; and their juices, after a hard frost breaks, will flow out in so copious a manner, as is scarce to be conceived. The willow, the poplar, and the walnut-tree, will all bleed also; and *fermentation*, of which their several juices are easily susceptible, will turn them all into palatable and strong wines. See BREWING.

To obtain an idea of these changes, we cannot consider it better, than in the procuring of a spirituous liquor from malt, by means thereof.

It is to be observed then, that the malt being made, as shewn under the article MALT, and then laid to infuse or mash in hot water, the rest of the process of brewing is nothing but a raising and directing of a *fermentation*, or intestine motion.

How such motion is mechanically affected, and how it brings forth such a spirit, may be conceived from what follows; supposing the reader acquainted with these common propositions in hydrostatics; viz.

1. That a body immersed in any fluid, specifically lighter than itself, will sink; otherwise it will emerge, and get to the top.

2. That if two equal bodies of different specific gravities be immersed in a fluid, lighter than either of them, the celerities of their descents will be as their gravities.

3. That

3. That if two unequal bodies of unequal specific gravities be immersed in a fluid, lighter than either, the velocities of their descents will be compounded of their gravities and dimensions together.

The same laws by which bodies descend, hold good in the ascent of those specifically lighter than the fluid.

Hence, in all heterogeneous fluids, the constituent parts of which are not fitted to associate and cohere, so as to form what is called an uniform homogeneous fluid, the heavier may be accounted as solid bodies immersed in a fluid specifically lighter; and the lighter parts, as such bodies in a fluid specifically heavier: since it may be demonstrated, that the component parts of all fluids, separately considered, are solid.

The liquor, therefore, called *wort*, which is a decoction of malt, may be considered as such an heterogeneous fluid, whose parts cannot be interchanged in their positions, till each has obtained such an elevation as corresponds to its proper gravity; but left this alone should fail of the intention, by not being sufficient to break those molecular and viscidities, which entangle the spirituous parts, and likewise to prevent their flying off at the surface, some portion of an already fermented substance is mixed with it.

In the fermenting of malt for distilling the spirit, the meal of unmalted corn is found necessary to be mixed with the malt, to prevent its excessive *fermentation*, and throwing off the matter of the spirit; but as diffusion is required in this case, a good quantity of yeast is added to quicken the *fermentation*, so that it may be finished in two or three days. More yeast is to be added if the weather be cold, and less if it be hot: the reverse of this is to be understood of meal, more of which is to be added in hot weather to check, and less in cold to hasten the operation, which in the present case is designed to be violent, contrary to what ought to be observed in the *fermentation* of wines, where the slower the operation is performed, the better the liquor will prove, and this may indeed here hold alſo in a leſs degree: for it is poſſible to ferment the wath ſo violently, that it ſhall ſoon end in putrefaction. Shaw's Lectures, p. 216.

This ſubſtance, termed *barm*, or *yeaſt*, conſiſts of a great quantity of ſubtle ſpirituous particles, wrapped up in ſuch as are viſcid. Now, when this is mixed with ſuch a liquor it cannot but much contribute to that inteſtine motion which is occaſioned by the intercourſe, and occurſions of particles of different gravities; as the ſpirituous particles will be continually ſtriving to get up to the ſurface, and the viſcid ones continually retarding ſuch an aſcent, and preventing their eſcape.

So that by theſe two concurring cauſes the particles extracted from the grain will by ſuch frequent occurſions be ſo comminuted, as continually to increaſe the more ſubtile and ſpirituous parts, until all that can be made ſo by attrition, be ſet looſe from their former viſcid confinements; and this appears by the warmth of the liquor, and the froth driven to the top; juſt at which time, if it be thrown into the ſtill, it affords ſome quantity of a highly inflammable ſpirit.

Moderate warmth much haſtens this proceſs, as it aſſiſts in opening the viſcidities, in which ſome of the ſpirituous parts may be entangled, and unbends the ſpring of the included air, which cannot but contribute to the rarefaction and comminution of the whole.

The viſcid parts, which are raiſed to the top, not only on account of their own lightneſs, but by the continual efforts and recurſions of the ſpirit to get uppermoſt, both ſhew when the ferment is at the higheſt, and prevent the finer ſpirits making their eſcape; for if this inteſtine luctus be permitted to continue too long, a great deal will get away, and the remaining liquor will grow flat and vapid, and raiſe little beſide phlegm in the ſtill.

A quantity of fixed air is extricated in the proceſs of *fermentation*, recovers its elaſticity, and being rarer and lighter than the fermenting liquor, riſes to the top, occaſioning an inteſtine commotion, and bearing with it ſome of the more volatile and ſpirituous parts of the liquor; but being heavier than the atmoſpherical air, reſts on the ſurface. See WORT.

Some of the proceſſes in chemiſtry ſeem to prove, that *fermentation* is not confined to animal and vegetable ſubſtances, but that mineral are alſo liable to it in ſome degree. If an ounce of lead and an ounce of biſmuth be melted together in an iron ladle, and an ounce of quickſilver be heated in another ladle, and all three mixed together, this makes an amalgamation, which appears perfectly homogeneous, and paſſes through leather in a running form, without leaving any thing behind. But this mixture being ſuffered to ſtand quiet for ſome hours, a groſs matter will ſeparate from it by degrees, and float upon the reſt, which will now run eaſily through leather, and leave the groſs matter behind. Here appear all the requiſites of *fermentation*. 1. A fluid form. 2. An uniform matter. 3. An inteſtine motion. And, 4. Anactual ſeparation of a groſſer matter leaving a thinner behind. Shaw's Lectures, p. 230.

Fermentation is a point of the utmoſt conſequence in medicine, and the animal œconomy: it is one of the principal means or inſtruments we have for altering, exalting, or calling forth the properties and powers of bodies. See DIGESTION.

The greateſt uſe of the theory of *fermentation* in medicine, will be in teaching what parts of the materia medica are moſt properly brought under this procedure; and how ſuch inteſtine motion does, in ſome things, deſtroy their virtues; for by ſome medicines an intention is aimed at which is not to be procured, but by their being ſpirituous, whereas, in others, the very contrary property is required: in ſuch caſes, therefore, when by any adventitious cauſe thoſe medicines get into a ferment, they are deſtroyed, and ſhould not be adminiſtered.

FERMENTED *liquors*. All *fermented* liquors abound with a ſuperabundant proportion of water; and if a very conſiderable quantity of it were taken away, they would become not only richer, but more durable, provided that ſo much of the aqueous humidity was retained, as was juſt ſufficient to preſerve the viſcous conſiſtence, to keep the ſaline part fluid, and to retain the ſlimy and unctuous parts expanded and mixed among the reſt. But as an actual and truly ſaline matter abounds in WINE and VINEGAR, and that of an acid, auſtere, and tartareous kind, when the ſpirituous part is drawn away, the wine becomes ſurpriſingly more auſtere; and when a large quantity of the watery part is ſeparated, this ſuperabundant ſaline, tartareous matter, coagulates into a cryſtalline form, and either falls to the bottom, or ſticks to the ſides of the caſk. For the ſubtile, oily matter, which makes the ſpirituous part in wine, blunts and takes off from a tartareous acidity, in the ſame manner that the addition of ſpirit of wine blunts, ſheathes, and dulcifies the acid, corroſive parts of ſpirit of nitre in making the ſpiritus nitri dulcis. But this tartareous ſalt abounding alſo with an undue proportion of ſo groſs and unctuous matter, cannot be diſſolved or diluted without a very large proportion of water, which being taken away, it is preſently converted into dry and ſolid cryſtals, as is the known caſe of cream of tartar. Hence it proceeds, that the auſterity and roughneſs of wine are the more preſerved, the more the wine is deprived of its ſpirituous parts. This experiment is familiar in our kitchens, where wine being burnt or boiled into ſauce, is found to have a much greater degree of auſterity, than the ſauce and wine had before it had undergone the action of the fire, and loſt its ſpirituous part. When the water is even by diſtillation plentifully drawn off from wine, not of a terreſtrial and chalky, but of a tartareous nature, a beautiful tartar will be found to cryſtallize, among the remaining maſs, in a conſiderable proportion. But though this ſuperfluous water that generally dilutes the wine, and weakens its taſte, might be advantageouſly ſpared from it, and it would thus become much more rich and noble, and at the ſame time more ſmooth and ſoft, through the loſs of ſome conſiderable portion of its tartar; yet this ſeparation cannot be effected by diſtillation, becauſe that carries away other parts as well as the water, and damages the whole, by taking off what ought to be the moſt carefully preſerved. The ſpirituous part is the life of all *fermented* liquors, it keeps the whole together, and in a manner embalms and renders them durable and not ſubject to corruption; it alſo in a great meaſure gives them that aromatic refreſhing and reſtorative virtue, and the beſt effects they have on the human body. Nor is this all; but the intimate and ſubtile union of this ſpirituous part with the reſt, is perfectly the ſole and entire cauſe of both the former effects, ſo that it by no means ſuffices to have the ſpirit barely preſent among the other parts, for then it might be drawn off and poured back again, without any damage to the wine; but the eſſential union is here diſſolved by taking it away, and can never be reſtored again by a ſimple re-affuſion. It is therefore deſtructive of the end propoſed, thus to break and diſſolve the texture of the wine, and this entirely ſubverts and deſtroys its nature. This inevitably proves the caſe, whenever wine is evaporated or diſtilled, which conſtantly requires a degree of heat capable of raiſing water into vapour, and hence the ſpirituous part being much lighter than the aqueous, flies off together with it, or before it, and the wine is left diſſolved in its texture, and without its ſoul. Upon this, the remaining ſaline unctuous maſs is ſo diſturbed, as no longer to remain connected, but it becomes thick and turbid, and afterwards runs impetuouſly into a kind of corruption, attended with acidity and ropineſs. All theſe circumſtances ſhew, that though the condenſing of wines, by taking away their ſuperfluous humidity, would be a very deſireable thing, yet it is by no means to be done by evaporation.

Fermented liquors are efteemed great antidotes to PUTREFACTION; accordingly the antiſeptic virtues aſcribed to them is aſſigned as one cauſe why the Turks are more ſubject than other people to the plague, and other contagious diſtempers. It is likewiſe obſerved, that beer, wine, and ſpirituous liquors, coming more into general uſe, has been one great means of ſuppreſſing putrid diſeaſes. See Pringle's Obſerv. on the Diſeaſes of the Army, p. 286. 294. and Macbride's Eſſ. eſſ. 3. See ANTISEPTIC, CROWNS, and SERVICE-*berry*, and WORT.

FERN, *Filix*, in *Botany*, the name of an order of plants belonging to the *cryptogamia* claſs, and comprehending ſixteen genera; among which are the horſe-hair, maiden hair, adder's tongue, ſpleen-wort, polypody, &c. to the laſt of which belong the common male and female *fern*, beſides a great number of other ſpecies. The leaves are compoſed of other leaves affixed on each ſide the middle rib, and thoſe are ſubdivided, almoſt to their rib, into other pinnulæ, or little leaves. The flowers have not been diſcovered, and the ſeeds grow in cluſters on the under part of the leaves. To this it is to be added, that there is alſo a peculiar face in the *ferns*, which diſtinguiſhes them at firſt ſight from the other plants of this kind.

The ſeeds of the ſeveral ſpecies of *fern* were wholly unknown to the ancients. Swammerdam, in his Bibliа Naturæ, claims to himſelf the honour of having firſt diſcovered them; but reappears from Hook's works, that Dr. William Cole ſent an account of the ſeeds of ſeveral of the plants of this kind to that author, in 1669, whereas Swammerdam declares his diſcovery of them to have been in 1673; ſo that it is plain that Dr. Cole's was prior to his by ſome years. The ſeed-veſſels of the common *fern*, the Engliſh and foreign maiden-hairs, the wall-rue, harts-tongue, and the like plants, are all ſimilar in their general form, their only differences being in the ſize, and in their arrangement on the plants. The number or quantity of the ſeeds is very different in different plants; but Mr. Miles obſerves, that the fewer ſeeds there are in any ſpecies, there is always the more in quantity of a ſort of ſpungy or fungous matter, which forms a kind of tubercle, not unaptly reſembling what is called ſows-ears, which ſeems a ſubſtance intended for the ſheltering of the ſeeds.

In the female *fern* and Engliſh maiden-hair, the whole ſurface of the leaf on the under ſide ſeems covered with a congeries of ſeeds, ſo that they guard one another, and therefore have leſs occaſion for a covering of fungous matter of this kind; yet even on theſe plants, when the ſeeds are fallen off, there are found ſmall membranes, a little curled, looking as if they had been raiſed with the edge of a fine pen-knife from the ſkin of the leaf, not unlike the pieces of ſkin that are raiſed off from the hand, in trying a pen-knife, or other ſharp inſtrument. In the common male *fern* there are found, at the proper ſeaſon, ſeveral brown ſpots placed in a regular manner; theſe are of a pale brown colour, and are principally compoſed of this fungous matter, the ſeed-veſſels being ſmall and inſerted round it. Phil. Tranſ. N° 461. p. 774.

Theſe ſeed-veſſels conſiſt of a ſtalk, by which they are inſerted into the leaf; this repreſents an elaſtic cord, and is ſurrounded by a great number of annular ribs, reſembling the carriages of the aſperia arteria; and indeed nothing in nature ſo exactly reſembles this cord or ſtalk, as the wind-pipe of a ſmall bird. This cord encircles the globular membranous pod wherein the ſeed lies, adhering to it, and dividing it into two hemiſpheres. See *Tab. of Microſcopical Objects, Claſs* 2.

The pod is compoſed of a fine whitiſh membrane, ſomewhat like that which lines the inſide of a pea-ſhell; the ſeeds are irregular in ſhape, and of a reticulated ſurface. The moſt advantageous way of viewing this is to uſe the common microſcope for opake objects, putting on a ſmall magnifier, and laying the ſeeds with their capſules, &c. as taken from the back of the plant, on a piece of poliſhed ivory. The proper time of the year is in the beginning of September, and then if the plant be newly gathered, the ſeed-veſſels often burſt while they are under inſpection, which is the method nature has taken for diſperſing the ſeed, and ſhew a very elegant appearance. Phil. Tranſ. N° 461. p. 782.

The common *female fern* is a very miſchievous and troubleſome weed to the farmers, being very difficult to deſtroy, where it has any depth of ground to root in. Its roots will often penetrate to eight feet deep, and ſpreading a great way, they will riſe again to the ſurface, and ſend up new plants at a conſiderable diſtance. In graſs land the beſt way of deſtroying them, is mowing the graſs three times a year, in ſpring, in May, and in Auguſt. Dung and aſhes are very good manure for lands which abound with them; but the beſt of all things for deſtroying them, is urine. *Fern* cut up when the ſap is in it, and laid to rot upon the ground, is a very good manure for land, and will mellow it ſo as to prevent its binding. Trees planted where *fern* grows, are obſerved to thrive very much, even though it be upon a hot gravel; the reaſon of this is, that the *fern* ſhades the roots, and keeps them moiſt and cool. Mortimer's Huſbandry, p. 316.

Scotch ſheep put into land where there is much *fern* growing among the graſs, generally deſtroy it in a little time, partly by their dung and urine, and partly by treading it down.

The root of the *male fern* is greatly recommended by medical writers, as a cure for rickets in children. Some alſo give it in powder, againſt worms; and it has the ſame virtues againſt the ſtone and gravel, with the reſt of the genus of capillary plants, aſcribed to it. It was frequently preſcribed by the ancients in diet drinks, for removing obſtructions, and in chronic caſes of all kinds, but is much diſuſed at preſent. Lemery, Dict. des Drog.

All the ſpecies of *fern*, and other vegetables, which carry their ſeeds on the back of their leaves, as moon-wort, and the like plants, poſſeſs the ſame general virtues of drying and ſtrengthening the viſcera, eſpecially the ſpleen.

FERN-*aſhes*. The poor people in many parts of the north of England, uſe aſhes of *fern* inſtead of ſoap, for waſhing their cloaths; they cut the plant green, and then burn it to aſhes, and make them up into balls with water; they dry theſe in the ſun, and keep them ready for uſe.

The aſhes of the common *female-fern* produce a very ſingular phenomenon in the common way of treating them and their ſalt. If a large quantity of theſe aſhes be procured, and the ſalt to the quantity of ſeveral pounds extracted from them in the common way, it will ſucceed better than in ſmaller quantities. The greater part of this ſalt being dried, if the remainder, which is more moiſt, be expoſed to the air to receive ſome of the vapours of it, this will ſoon become fluid, or an oil, as it is more improperly called, *per deliquium*. The reſt of the lixivium, which will be very heavy, and of a deep blood-red, or claret-colour, being ſet by in a glaſs-veſſel unſtopped for five or ſix months, there will be found at the bottom of the liquor a very large quantity of ſalt precipitated to the thickneſs of about two inches on the bottom of the veſſel. The lower part of this will have all the ſoulneſs, and appear diſcoloured; but the upper part will be extremely pure and white. From the ſurface of this part there will grow up a number of plants, in appearance ſtanding erect, and at ſmall diſtances from one another. Theſe are only the laſt cryſtallizations of the ſubſiding or ſeparating ſalt, but they have a regularity that is very ſurpriſing; they vary conſiderably in ſize and weight, but are all of the ſame ſhape, exactly reſembling ſo many plants of the common unbranched *fern*, ſending out a great number of regular leaves on each ſide the ſtem. Theſe ramifications of the ſalt will remain many weeks in this perfection, if the veſſel be not ſtirred: but they are ſo tender, that the leaſt motion deſtroys them, and they afterthis never form themſelves again. Phil. Tranſ. N° 105.

FERN-*oil*, in *Pottery*, a name given by our merchants who have been in China, to a ſort of varniſh, which the Chineſe uſe in their porcelain manufactories. It is alſo called lime-oil, and is a thing ſo eaſily made, that it would be worth attempting what might be done with it, in our imitations of the porcelain. They make it in this manner: they take a large quantity of *fern* well dried, and ſpreading a covering of it over a piece of ground ſufficient for the quantity of oil they intend to make, they lay upon this a coat of large lime-ſtones, newly calcined into lime; on theſe they ſprinkle with the hand a ſmall quantity of water juſt to ſlake them. They cover this bed of lime with another of *fern*; and ſo on, till they have raiſed it to eight or ten feet high; they then ſet fire to the *fern*, this burns away in a little time, and leaves a mixture of the lime and its own aſhes. This mixture is laid in the ſame manner between beds of more *fern*, and burnt again. This operation is repeated five or ſix times. Obſerv. fur les Coutom. de l'Aſie.

When the laſt calcination is finiſhed, the mixture of lime and aſhes is carefully gathered up, and thrown into large veſſels of water, and with every hundred weight of it, they put in one pound weight of kekio; they ſtir the whole together; and when the coarſer part has ſubſided to the bottom, they take off the finer, which ſwims at the top in form of a fine cream, and putting it into another veſſel of water, they let it ſubſide to the bottom by long ſtanding; they then pour off the water, and ſave the ſediment in form of a thick oil.

This they mix with the oil of ſtone, prepared by powdering and waſhing in the ſame manner a particular ſort of

of ſtones, and with this they cover all the veſſels that they intend to varniſh. The *fern* aſhes have a very great ſhare in the advantage that this oil has over our common varniſhes; and the Chineſe tell us, that they once inſtead of *fern* uſed the wood of a tree, called *te tiki*, and they ſuppoſe that the ſuperiority of the old porcelain over the preſent, is owing to the uſe of this tree inſtead of the *fern*; but it is now too ſcarce among them. The new manufacture which we have at Briſtol, excels every thing that has been done of the like kind, in the beauty of the varniſhing; and it is ſaid, they have founded their advantage on an imitation of this and the Chineſe oil of ſtone. Theſe two oils, as they are called, are always mixed together; and they muſt be carefully preſerved of the ſame degree of thickneſs, or elſe all the varniſhing will not be even.

FERN, *flowering*. See OSMOND *royal*.

FERN, *common*, or *tree male*. *filix*. See MILT-*male*.

FERN, *ſweet*, in *Botany*, the name of a genus of plants, the characters of which are theſe: the flowers are not diſcovered; the ſeeds grow in cluſters on the backs of the leaves, and the whole plant reſembles the larger or common *ferns*.

FERN, *male* or *moon*. See HEMIONITIS.

FERN, *ſweet*. See CHERVIL.

FERNAMBUC. See BRASIL *wood*.

FEROENSIS *Morgan*, in *Natural Hiſtory*, a name given by ſome authors to a marley earth, found principally in the fiſſures and cavities of ſtone, and called by the generality of later naturaliſts, *aqueous minerals* and *lac lunæ*; and by the ancients, *terra*, or *creta ſolenarſica*. See LAC *lunæ*.

FERRA, in *Ichthyology*, the name of a fiſh, called alſo by ſome *gunnid* or GUINIAD.

FERRARIA, in *Botany*, a genus of the *gynandria triandria* claſs. its characters are theſe: the flower is incloſed in a double ſpatha or ſheath, out of each of which is produced one flower; the flower has ſix oblong acute-pointed petals, three of which are alternately longer than the other, and they ſeem to be joined at their tails; their borders are fringed, turned backward, and ſilky. It has three ſtamina which riſe above the petals, and a roundiſh three-cornered germen ſituated under the flower, which afterward turns to an oblong ſmooth three-cornered capſule, crowned by the decayed petals of the flower, with three cells, wrapped in the permanent ſheath of the flower; in each cell are lodged many ſmall round ſeeds. There are two ſpecies, natives of the Cape of Good Hope. There is a great ſingularity in the root of one of theſe ſpecies, that it vegetates only every other year, and ſometimes every third year: in the intermediate time it remains inactive, though very ſound and good. Miller.

FERRARIA is alſo a name uſed by ſome authors for agrimony; and by others, in particular by Lobel, for the ſcrophularia or fig-wort.

FERRET, *Viverra*, in *Zoology*, an animal of the MUSTELA or WEASEL kind, called by ſome alſo MUSTELA *ſylveſtris*, FURO, and PUTORIUS.

It is of a middle ſize, between the weaſel and pole-cat: its head is ſmall and ſtatiſh; its ears ſhort, erect, and very wide; its noſe or ſnout long, like that of a dog; and its eyes ſmall and red; its colour is a pale yellowiſh white; the back and ſides a little darker than the belly; and its feet have all five claws each; it breeds very well with us, but is ſaid not to be a native here, but brought from Africa. Ray's Syn. Quad. p. 198.

It was originally brought from Africa into Spain, in order to free that country from the multitude of rabbits with which it was over-run; and from thence the reſt of Europe was ſupplied with it.

This creature has but one note in her voice, which is a ſhrill, but ſmall whining cry. The female uſually brings forth ſeven or eight young ones at a time; ſhe carries them in her body forty days, the young ones are blind for a long time after they are littered. When they are tamed, they are to be fed with milk, and with barley-bread; they will faſt a long time; when they walk they ſet up their back which is otherwiſe ſo long that it would be troubleſome to drag it on; when they are touched, they ſmell very diſagreeably; they naturally ſleep very much. The *ferret* is a bold and audacious animal, and is an enemy to almoſt all others. It does not eat the fleſh of the creatures it kills, but ſucks their blood. The uſe we make of this creature is the ſending it into rabbit-holes to drive them out; but we are obliged to faſten up their mouths that they may not tear the rabbits to pieces; but it ſtill is able to annoy them with its claws, and ſoon drives them out. It feeds on milk, ſmall birds, and the fleſh of animals, and is a creature eaſily kept tame, and will breed and bring up its young in that ſtate; and theſe will naturally hunt the rabbit, in the ſame manner as their parents.

When the warrener has occaſion to uſe the *ferret* to catch rabbits, he firſt makes a noiſe in the warren to frighten them all into their holes; then he pitches his nets; and having muzzled the *ferret*, that he may not bite the rabbits, he turns him into their holes to frighten them out; and then the dogs drive them into the nets that are ſet for them. Warreners aſſert, that the FITCHET will mix with the *ferret*; and they are ſometimes obliged to procure an intercourſe between theſe animals to improve the breed of the latter, which, by long confinement, becomes leſs eager after rabbits, and leſs uſeful: Buffon denies this; but Mr. Pennant alleges a fact in proof of it. Zoology, vol. i. p. 91.

FERRET, *Indian*, *viverra Indica*, a name by which ſome have called the animal known in America by the name of QUIPPILE and QUIL. See ICHNEUMON.

FERRETS, in *Gloſs-making*, the irons with which the workman tries the melted metal to ſee if it be fit to work.

It is alſo uſed for thoſe irons which make the ring at the neck of bottles

FERRETES *d'Eſpagne*, in *Natural Hiſtory*, a name given by authors to certain ſtones of a regular figure, found on the ſides of a rock in Spain; and as has been ſince diſcovered very plentifully on the bottom and ſides of the Fontaine de Saluſ, near Bagneres in France, and in other places in the country thereabout. They are ſmall ſtones of the colour of ruſty iron, and of a regular figure, being either parallelepiped with oblique angles, of which the ſides are unequal, or ſmall ſolid bodies with ſix ſides, only differing from cubes or dice in this, that the ſurfaces are not perfectly perpendicular to one another, but a little inclined; they are alſo commonly longer than they are broad, and broader than they are high. The largeſt of theſe fall ſhort of an inch in meaſure, being about eleven lines in length, nine and a half in breadth, and ſix in height; but they are uſually a great deal ſmaller, and are ſometimes found in cluſters, a hundred or more together; and ſome of them have ſhining ſkins, reſemingly of a metallic ſubſtance. Theſe ſtones are not only found in the bath, but in the digging of a way for a common road from the town of Bagneres to it, they were found lodged in their proper ſtratum. The workmen here met with a bed of a ſoft kind of ſlate of a bluiſh colour, but lighter than that of the common ſlate. The whole rock they worked through was compoſed of layers or beds of this, lying almoſt parallel over one another. The ſubſtance of the ſlate ſeemed to be a compoſition of fibres or ſtrings laid regularly ſide by ſide by one another, and all equally inclined to their beds or layers. Whence it comes, that upon breaking them with a hammer, the pieces ſometimes are pretty like the figure of a regular parallelepiped with oblique angles. Upon a narrower examination of this ſort of ſlate, there are uſually found in it a great number of parallelepiped ſtones like thoſe before ſpoken of, only ſmaller; and ſeveral little black ſpots diſcovered in other parts of the ſtone when they are examined with glaſſes, prove alſo to be regularly figured bodies of the ſame kind.

Every one of theſe ſtones, ſo long as it remains in the rock, is always found between two bundles or cluſters of tranſparent fibres, of which generally one is placed on the one, and the other on the oppoſite ſide; theſe cluſters of fibres are largeſt in the largeſt ſtones; however, they are always found even about the ſmalleſt in ſome quantity. Phil. Tranſ. N° 477. p. 30.

FERRETTO, in the *Gloſs-trade*, a ſubſtance which ſerves to colour glaſs. This is made by a ſimple calcination of copper, but it ſerves for ſeveral colours. There are two ways of making this; the firſt is as follows: take thin plates of copper, and lay them on a layer of powdered brimſtone, in the bottom of a crucible; over theſe lay more brimſtone, and over that another layer of the plates, and ſo on alternately till the pot is full. Cover the pot, lute it well, place it in a wind furnace, and make a ſtrong fire about it for two hours. When it is taken out and cooled, the copper will be found ſo calcined that it may be crumbled to pieces between the fingers like a friable earth; it will be of a reddiſh, and in ſome parts a blackiſh colour. This muſt be powdered and ſifted fine for uſe. Neri's Art of Glaſs, p. 30.

The other way is leſs eaſy, but it makes a more valuable *ferretto*. It is this: make a number of ſtratifications of plates of copper and powdered vitriol alternately in a crucible, which place on the floor of the glaſs-furnace near the eye, and let it ſtand there three days; then take it out, and make a new ſtratification with more freſh vitriol, and calcine it again as before; repeat this operation ſix times, and a moſt valuable *ferretto* is produced.

FERRIFIC *Cauſe*, a term uſed by ſome writers to expreſs that principle to which what they call the production or generation of iron in burnt bodies, in which no iron could be diſcovered before burning, is owing. It is the

general opinion of the present philosophers, that this iron thus discovered in the ashes of plants, and the like burnt substances, really existed there before, and only needed the disunion of the concreted body to the being-ing of its parts together. If this be the case, there is evidently no production of iron in the case, and therefore the term *ferrific* is a word without meaning. Becher, however, in his supplement to his Physica Subterranea, is of a very different opinion, determining, that the iron is really produced in these cases during the action of the fire; and that by the transmutation of some other matter into iron; and from this he argues the possibility of gold-making among chemists by transmuting something else into gold, as some other substance is in this case transmuted into iron.

FERRUGINOUS, denotes a thing to partake of the nature of iron, or to contain particles of that metal.

It is particularly applied to certain mineral springs, whose water in their passage along the strata of the earth meets with the ore of this metal, or with pyrites containing it, part of which they wash off, and carry with them; and thus become impregnated with the principles thereof. Such are what we call CHALYBEAT WATERS.

The waters of Tunbridge, those of Forges, and of the iron spring at Bourges, and many others, are *ferruginous*.

FERRUGO, the rust of IRON, or a kind of calx found on the surface thereof.

The rust of iron is a restringent; applied by way of pessary, it represses the floor uterinus; and drank, prevents conception: it cures the erysipelas, and exanthematous eruptions. It is of good use in a paronychia, roughness of the eye lids, and a condyloma. It also strengthens the gums, relieves under the gout, being rubbed on the part affected, and makes the hair grow after an alopecia. Wine or water, in which red hot iron has been quenched, being drank, is good for the coeliac passion, dysentery, disorders of the spleen, cholera morbus, and relaxations of the stomach.

FERRUM. See IRON.

FERRUM *equinum*. See *Horse-shoe* VETCH.

FERRY, a liberty by prescription of the King's grant to have a boat for passage upon a river, for the carriage of horses and men for a reasonable toll: it is usually to cross a large river. Termes de Ley.

A *ferry* is no more than a common highway; and no action will lie for one's being disturbed in his passage, unless he alledge some particular damage, &c. 3 Mod. Rep. 294. The not keeping up of a *ferry* has been held to be indictable.

FERTILITY, FRUITFULNESS, that quality which denominates a thing fertile or prolific.

The Egyptian nitre or natron renders the ground exceedingly *fertile*. M. de la Chambre observes, that the plants grow in such abundance in Egypt, that they would choak one another if they were not hindered by throwing sand upon the fields, informing us, that the Egyptians must take as much pains to lessen the richness of their soil as other nations do to increase that of theirs. Phil. Transact. N° 160.

Nothing can produce *fertility* in either sex but what promotes perfect health; nothing but good blood, spirits, and perfect animal functions, that is, high health, can beget perfect FECUNDITY; and therefore, according to Dr. Cheyne, all means and medicines, all nostrums and specifics to procure *fertility*, different from those which procure good blood and spirits, are arrant quackery and cheating. He says, that water-drinking males are very rarely infertile; and that if any thing in nature can prevent *infertility*, and bring fine children, it is a milk and seed-diet, persevered in by both parents.

FERULA, a little wooden pallet or slice, reputed the schoolmasters sceptre wherewith he chastises the boys by striking them on the palm of the hand.

The word is Latin, and has also been used to denote the prelates crozier and staff. It is supposed to be formed of the Latin, *ferire, to strike*; or, perhaps, *ferula* in this sense may be derived from the name of a plant, called in Latin, *ferula*; in English, *fennel-giant*; the stem whereof was anciently used to correct children with.

Under the eastern empire the *ferula* was the emperor's sceptre, as is seen on divers medals; it consists of a long stem or shank, and a flat square head. The use of the *ferula* is very ancient among the Greeks, who used to call their princes ῥαβδοφόρους, q. d. *ferula bearers*.

In the ancient eastern church, *ferula* or ῥαιθὸν signified a place separated from the church; wherein the penitents or the catechumens of the second order, called *audientes*, *substrati*, and *genuflectentes*, were kept, as not being allowed to enter the church; whence the name of the place, the persons therein being under penance or discipline: *sub* ferula *erant excisi*.

FERULA, in *Botany*. See FENNEL *giant*.

FERULÆ, a word used by the ancients to express the horns growing on the deer or stag at the age of two years.

FERULÆ, among *Surgeons*, called also SPLINTERS, are little chips of different matter; as of wood, bark, leather, paper, &c. applied to bones that have been disjointed when they are set again.

The bark of the herb fennel giant, called by some in Latin, *ferula*, was anciently much used on this occasion; whence the name *ferula* became common to all.

FERULACOLI, in *Botany*, a name by which some authors have called the hibiscus, or treacle mustard.

FERULAGO. See FENNEL-*giant*.

FERZAA, in *Natural History*, a name given by the Persians to that gem which we call the turquoise or Turkey-stone, a blue, opake, and soft gem. See TURCOIS.

FESCENNINE, in *Antiquity*, *Fescennine verses* were a kind of satirical verses, full of wanton and obscene expressions, sung or rehearsed by the company, with many indecent gestures and dances, at the solemnization of a marriage among the Romans. Hor. ep. i. lib. v. 145.

The word is borrowed, according to Macrobius, from *fascinum*, *a charm*; the people taking such songs to be proper to drive away witches, or prevent their effect; but its more probable origin is from Fescennium, a city of Campania, where such verses were first used.

FESOLI, or FESOLI, *congregation of*. See JERONYMITES.

FESSE, in *Heraldry*, one of the nine honourable ordinaries of the escutcheon, which it divides horizontally in the middle, and separates the chief from the point. It is supposed to represent a broad girdle or belt of honour, such as those with which knights at arms were anciently girded.

It possesses the centre of the escutcheon, and contains in breadth one third part thereof. Thus, he beareth azure, a *fesse*, or, by the name of Elliot. See *Tab. Heraldic. fig.* 22.

When the *fesse* takes up less than its proper breadth, it is called a *bar*.

FESSE-*point* is the exact centre of the escutcheon.

It is thus called, as being the point through which the *fesse* line is drawn from the two sides; and accordingly it divides the escutcheon into two equal parts when the escutcheon is parted *per fesse*.

FESSE-*ways*, or *in* FESSE, denotes things borne after the manner of a *fesse*; i. e. in a line or range, across the middle of the shield, which the French call *en fesse*.

FESSE, *party per*, implies parted across the middle of the shield, from side to side, through the *fesse* point.

This the French express by one word, *coupé*.

FESSIER, in *Anatomy*, the name given by the French writers to what others call the gluteus, or, according to Riolanus, the glautius. There are three muscles of this name among authors, the GLUTEUS *major*, *medius*, and *minor*, and the French call them the grand, moyen, and petit *fessier*.

FESTA *in capp.*, in *Middle Age Writers*, grand holidays, in which the whole choir of the cathedrals wore caps.

FESTI *Dies*, among the ancients, were *festi-days* or holidays.

Numa distinguished the days of the year into *festi*, *profesti*, and *interesti*. The first were those dedicated to the gods; and the second were those allowed to men for the management of their own affairs: the third were shared between the gods and men.

The *festi dies*, again, were divided, according to Macrobius, Saturn. cap. 16. into *sacrificos*, *epulos*, or banquets; *ludi*, or games, and *feriæ*; and the *profesti* into *fasti*, *comitiales*, *conperendini*, *stati*, and *præliares*.

FESTING *Men*. See FASTERMANS.

FESTING-*penny*, earnest given to servants when hired or retained. It is so called in some northern parts of England, from the Saxon, *festnian*, *to fasten*, or *confirm*.

FESTINO, in *Logic*, one of the moods of the second figure of syllogisms.

In a syllogism *in festino*, the first proposition is an universal negative; the second, a particular affirmative; and the third, a particular negative.

FESTIVAL. See FEAST and FESTUM.

FESTOON, in a *General Sense*. See GARLAND.

FESTOON, in *Architecture* and *Sculpture*, is a decoration in form of a garland or cluster of flowers.

The word is French, *feston*, which signifies a *garland*, formed of the Latin, *festum*, *fest*.

It consists of a string or collar of flowers, fruits, and leaves, tied together, somewhat biggest in the middle, and suspended by the two extremes; from which, beside the main part which falls down in an arch, two lesser parts hang perpendicularly.

This ornament is made in imitation of the *festoons* or long

long clusters of flowers, hung by the ancients on the doors of their temples, &c. on festival occasions.

Festoons are now chiefly used in freezes, tablets, and other vacant places, required to be filled up and adorned. They are sometimes used over or under a niche.

FESTUCA, *Fescue-grass*, in the *Linnæan System of Botany*, the name of a kind of oat-grass, which makes a distinct genus of plants of the *triandria digynia* class; the characters of which are, that the calyx is a many-flowered glume, and is bivalve, erect, and contains the flowers ranged together in a slender spike; the valves are straight, oblong, pointed, without awns, or beards, and the lower is the smaller; the flower is compoted of two valves, the lower is the larger, this is of the shape of the cup, but it exceeds it in size; it is somewhat cylindrical and pointed, and is terminated by a straight beard or awn; the ftamina are three capillary filaments, shorter than the flower; the antennæ are oblong; the germen is of a turbinated form; the styles are two in number, and are short and bent backward; the ftigmata are ſingle; the flower cloſely ſurrounds the ſeed, which is ſingle, oblong, ſlender, extremely ſharp-pointed at each end, and marked with a longitudinal furrow.

FESTUM, in a *General Senſe*. See FEAST.

FESTUM, in our *Law-books*, is frequently uſed for a general court or aſſembly, becauſe ſuch were anciently always kept on the great feſtivals of the year.

Thus, in our chronicles, we read, that in ſuch a year the king kept his *feſtum* at Wincheſter, &c. that is, he kept a court there at that time: *Rex apud Winton. maximum feſtum & conventum celebravit, tempore Natalis Domini, convocatis illuſtribus principibus & baronibus totius regni.*

To FETCH *Way*, in *Sea-language*, is to be ſhaken or agitated from one ſide to another. The terms are uſually applied to a maſt, bowſprit, &c. when it is not ſufficiently wedged, being looſe in the partners; or to any body which is moved by the rocking of the ſhip, for want of being well ſecured.

FETCHING *the Pump*, is the act of pouring water into the upper part of it, to expel the air which is contained between the lower box or piſton and the lower end of the pump that reſts on the ſhip's floor; and accordingly to make the water paſſed into the chamber communicate with that in the bottom of the pump-well, ſo as to be thrown out above by ſtriking with the break or handle.

FETFA, in *Modern Hiſtory*, is a name which the Turks give to the written judgments or deciſions of the muſti. The word in the Turkiſh language ſignifies *ſentence*, and in Arabic, the *reply* or *judgments of a wiſe man*.

FETICHE, in *Modern Hiſtory*, a name given in Guinea to their divinities; one of whom is ſuppoſed to preſide over a whole province, and one over every family. This idol is a tree, the head of an ape, a bird, or any ſuch thing, as their fancy ſuggeſts.

FET-*Lock*, in the *Manege*, a tuft of hair growing behind the paſtern-joint of horſes.

Hence, the joint where it grows is called the *fet-lock joint*.

FŒTUS. See FOETUS.

FEUD, FEODUM, the ſame with fief or fee.

Eſtates in land were originally at will, and then they were called *munera*; afterward they were for life, and then they were called *beneficia*; and for that reaſon the livings of clergymen are ſo called at this day; and afterward they were made hereditary, when they were called *feoda*, and in our law *fee-ſimple*.

When Hugh Capet uſurped the kingdom of France, about the year 947, to ſupport himſelf in ſuch uſurpation, he granted to the nobility and gentry, that whereas till then they generally enjoyed their honours for life, or at will only, they ſhould from thenceforth hold them to them and their heirs. However, under the reign of Ludovicus Pius, who ſucceeded his father A. D. 814, grants of hereditary fiefs were frequent in France. Muratori obſerves, that the word *feudum*, which came to be ſubſtituted in the place of *beneficium*, does not occur in any authentic charter previous to the eleventh century; and Dr. Robertſon adds, that a charter of king Robert of France, A. D. 1008, is the earlieſt deed in which he has met with the word *feudum*. Hiſt. Ch. V. vol. i. p. 269. This was imitated by William, called the Conqueror, upon his acceſſion to the crown of England; for till his reign *feuds* or fees were not hereditary, but only for life, or for ſome determinate time. See FEE.

Feuds were called by various names, according to their reſpective natures; as *feudum antiquum*, which deſcended to a ſon, &c. from his anceſtors; *apertum*, reſulting back again to the lord of the fee, where the blood of the laſt perſon laſt ſeiſed in fee-ſimple is utterly extinct and gone; *honorarium* and *individuum*, a title of nobility, not of a diviſible nature, and deſcendible to the eldeſt ſon in excluſion of all the reſt; *improprium*, an improper or derivative *feud*; *paternum*, deſcending to the ſon from the mother; *novum*, one newly acquired by the ſon, to which, in ancient times, only the deſcendents from his body could ſucceed, by the known maxim of the early feudal conſtitutions; *novum* held *ut antiquum*, deſcendible in the ſame manner as a *feudum novum*; *paternum*, deſcendible from father to ſon; and *proprium*, a proper *feud*, diſtinguiſhed from one improper, which are the two grand and general diviſions. Blackſt. Com. vol. ii.

FEUD is alſo uſed in our ancient cuſtoms for a capital quarrel or enmity, not to be ſatisfied but with the death of the enemy; and thence uſually called *deadly feud*.

Feud, called alſo *feida*, and *faida*, in the original German ſignifies *guerrom*; i. e. *bellum*, war. Lambert writes it *feeth*, and ſaith it ſignifies *capitales inimicitias*, or *implacable hatred*.

In Scotland and the North of England, *feud* is particularly uſed for a combination of kindred, to revenge the death of any of their blood, againſt the killer and all his race, or any other great enemy.

FEUDAL, or FEODAL, of, or belonging to a *feud* or *fee*. We ſay, a *feudal* matter, *feudal* juriſprudence, *feudal* ſeiſure, &c. A *feudal* lord, in default of fealty and homage from his vaſſal, may ſeize the fruits of the fee. A Neapolitan lawyer, called Caravita, has a Latin treatiſe of the *feudal* law, intituled, Prælectiones Feodales.

When once the uſe of fees was thoroughly eſtabliſhed in France, they would needs extend it much further; and almoſt all the great offices of the crown thus became *feudal*; even the courts of juſtice were drawn in; in order to which, they were annexed to certain lands or revenues.

The deſign of theſe infeodations was to render the offices hereditary, after the manner of fees, which were now become ſo; and thus the offices of the grand chamberlain, grand butler, &c. came to be held by hereditary right.

As the Northern nations brought in the uſe of coats of arms, by preſerving down in their families the armorial bearings of their anceſtors, ſhields, &c. as hereditary marks of honour, ſo they alſo, according to ſome, brought in the *feudal* law, by means of which arms grew up to further perfection, as is evident by many armorial figures of ancient families, repreſenting the acknowledgments and ſervices they were obliged to perform to their own lords and ſuperiors.

Thus, roſes, cinquefoils, ſpur-rowels, bow and arrows, hunting horn, ſhips, and the like figures, were expreſſive of the ſervices they were bound to do their lord; and hence theſe figures have become common in arms throughout all Europe. For inſtance, the old barons of Arran and Lorn were obliged to furniſh their lord with a ſhip in time of war; and thence it is that their arms carry ſhips or lymphods to this time.

FEUDATARY, or FEODATARY, a vaſſal or perſon who holds of a ſuperior in fee; i. e. on condition of yielding him fealty and homage, or other ſervice. See VASSAL. The electors, princes, and free cities, of Germany, are all *feodatories* of the emperor.

FEUDBOTE, a recompence for engaging in a feud or action and for the damages conſequent thereon; it having been the cuſtom of ancient times for all the kindred to engage in their kinſmen's quarrels; according to that of Tacitus De Moribus Germanor. *Suſcipere tam inimicitias ſeu patris, ſeu propinqui, quam amicitias, neceſſe eſt.*

FEU *de joie*, in the *Military Art*. See *Running* FIRE.

FEUDIST, a lawyer, or doctor learned, or much converſant in feuds or fees. Du-Moulin is reckoned a great *feudiſt*.

FEVE. See AURELIA.

FEVER, FEBRIS, in *Medicine*, a diſeaſe, or rather claſs of diſeaſes, whoſe characteriſtic is a preternatural heat felt through the whole body, or, at leaſt, the principal parts thereof, attended with other ſymptoms.

Sydenham defines a *fever*, a ſtrenuous endeavour or effort of nature to throw off ſome morbific matter that greatly incommodes the body. Quincy defines it, an augmented velocity of the blood; others, a fermentation of the blood, accompanied with a quick pulſe and exceſſive heat.

Fevers are of various kinds, denominated and diſtinguiſhed from the particular cauſes that produce them; the time they continue; their acceſſes and returns, and their different ſymptoms.

Riverius reckons above thirty different kinds of *fevers*; and Sydenham has increaſed them to double that number; but certainly phyſicians have obſerved ſomething common to all theſe diſeaſes, which made them denominate them *fevers*. A late author thinks, that the conſideration of what conſtitutes a *fever*, which he thinks

very

very simple and obvious, with its true causes and genuine effects, will give a more just and clear notion of the disease, and lead to a more rational practice than all that has been said by authors at so great length on these falsale and unnecessary distinctions. He thinks the most natural and useful division of *fevers* is into continued and interrupted; and he conceives they may all, when considered simply, and not as the effect of another disease, be reduced to one or other of these two sorts. Medic. Ess. Edinb. vol. i. p. 264, 265.

In every *fever* from an internal cause, the three chief observables are these: first, an universal trembling, and then an increased heat and quick pulse: a *fever* almost always begins with a cold or shivering; and soon after, the pulse growing quicker, affords the primary diagnostic of a *fever*. The health of the patient seems to be the primary aim of nature in *fevers*, though they often terminate in death.

By *Dr. Brown* Langrish's statical experiments made on the blood of people in acute continual *fevers*, compared with what he gives of the blood of three young men in perfect health, it appears, that in such *fevers* the serum is in less proportion, and the crassamentum is more viscid and tenacious than in health. The indications of cure from which are plain. See his Modern Theory and Practice of Physic, p. 67, 68.

By the chemical analysis it is proved, that in acute *fevers* the falsoe and sulphureous parts abound more than in health; and that the urine is impregnated more and more with these saline and sulphureous principles, as the symptoms abate upon a crisis by urine.

FEVERS, *fevers of.* These are an accelerated progressive motion of the blood, distinguished by the quickness of the pulse; this is succeeded by an increased heat in the body, and immediately after this the tonic motion of the parts is either constringed or relaxed. This is seen in the face: in the first case, it becomes red and bloated; in the latter thin and pale: these symptoms are succeeded by an immoderate thirst, and a loathing of food of all kinds; an abhorrence of sleep, or disturbed and unrefreshing sleep; and a peevishness or uneasiness in the temper, with an extreme sensibility of every thing, and a neglect of the common business of life: after this there is a great loss of strength, and an inaptitude to any motion; a sensation of pain in some part; a very uneasy and difficult respiration; a sweating more than usual; and finally, there is a change in the urine, its colour being usually very high, and its consistence thicker than that of persons in health. When the *fever* comes on gradually, the patient generally complains first of languor, listlessness, soreness of the flesh, or of the bones, as it is vulgarly expressed; heaviness of the head, loss of appetite, sickness, with clamminess of the mouth; after some time there succeed excessive heat, violent thirst, inability to sleep, &c. When the *fever* attacks suddenly, it always begins with an uneasy sensation of excessive cold, accompanied with debility and loss of appetite; the cold is frequently attended with shivering, oppression about the heart, and sickness of stomach, or vomiting. Boerhaav.

FEVERS, *general causes of.* These are an overheating the blood by exercise, and thus throwing it into violent commotions; violent and sudden cooling of the body when very hot; the abuse of spirituous liquors, and the eating large quantities of foods hard of digestion; a watchfulness beyond the usual custom; such as long sitting up by the sick, or the like; and the suppression of any accustomed evacuation, particularly of habitual haemorrhages by the nose or other parts. Besides these, the passions of the mind very frequently throw people into *fevers*; and it is observed also, that persons often accustomed to have *fevers* are much more easily thrown into them on slight accidents than any others. To all these causes are to be added those of contagion, unwholesome air, and external or internal injuries.

FEVERS, *prognostics in.* All *fevers* are in their nature salutary, being the means nature uses to rid herself of something that oppresses her, yet they are often fatal in the event; but this is rather to be attributed to the fault of the constitution than of the *fever*. The cause of the disease being impeded, and other diseases coming on, the patient often dies under them; so that the most judicious physicians observe, that people rather die with a *fever* than of a *fever* in these cases.

It is to be observed in general, that of the great number of persons who have *fevers*, very few proportionably die of them.

Fevers very often are cured by nature alone, and go off very happily only by the patient's abstinence, a quiet state, and keeping up the natural evacuations. In this manner great numbers recover without the help of medicines; a number almost as great is destroyed by medicines, which, when administered by persons who have not sufficient judgment, interrupt nature, and prevent the necessary excretion. *Fevers* go off, according to the language of physicians, either by a crisis or lysis: in the first case, they leave the patient at once, after the critical days; in the other, they wear off gradually, growing slowly less and less violent. The acute *fever* usually goes off in the first way; the intermittents in the other. Critical evacuations, of whatever kind, when they happen in sufficient quantity, bring with them a sort of instantaneous cure, the patient becoming well and easy from them, though immediately before he was in the utmost anxiety and uneasiness. No *fever* ever goes off without sweating, and a change in the urine. But in *fevers*, in general the sweats do not come on at first, but afterwards; and in general, the sweats never come on during the violence of the burning heat, but when that remits a little, the sweat breaks out. If it appears during the excessive heat, the presage is bad, at least, it is of no use or good to the patient. Sweats coming on at a proper time, and flowing to a proper degree, bring on recovery; but when they are suppressed, the disease becomes worse; there is pain and lassitude in the limbs, and the disease is protracted in length, and from an acute, becomes a slow *fever*. It also there be no change perceived in the urine, and the heat do not exceed the ordinary standard, it is a fatal prognostic for the patient; and the old physical axiom is usually verified, that while the pulse and the urine are well in *fevers*, the patient dies.

A dejection of spirits in a *fever*, and a melancholy state coming upon a person usually chearful when well, is always a bad omen.

The several different kinds of *fevers* have their stated times in which each attacks the patient. Tertians usually seize people about dinner-time, and are particularly common about the period of the vernal equinox. Quartans usually make their first attack about four or five o'clock in the afternoon, and are more common in autumn than at any other season of the year. The synocha, or continent *fever*, expressly so called, usually attacks persons in the morning before day-break. Bilious *fevers* usually make their first attacks about the time of sun rise, and are most common in the midst of summer. The catarrhal *fevers*, finally, most commonly attack persons in the evening, and they are most frequent about the equinoxes. The more any *fever* departs from its usual course, the worse is the prognostic; any *fever*, when it has been improperly treated by medicines, becomes much more stubborn and difficult of cure than when it has been left to itself. The particular medicines which disturb the course of nature in *fevers*, and by that means render them more difficult of cure, are astringents, too powerful absorbents, opiates, &c. And it is observed, that when *fevers* go off happily and easily, especially when they go off of themselves without medicines, the patient always enjoys a better state of health after than he had before. Junker's Consp Med. 257.

FEVERS, *method of cure in.* The physician in all *fevers*, is to endeavour to make himself the servant and assistant of nature: what nature endeavours in the beginning and increase of the disease, is to prepare, dispose, and search the noxious matter; and in the state and decline of it, to eliminate and evacuate the matter so prepared by the proper passages. The whole business of art is, therefore, to assist nature in these two efforts of secretion and excretion of the matter.

The method of doing this in every particular species of *fever*, is to be seen under their several particular heads; but as we are here treating of *fevers* in general, it may be proper to give the method of treating them as *fevers*, without running into the several sub-distinctions.

The remedies which we are to give to assist the secretion and preparation of the morbid matter, are the diluting and cooling liquors in general: such are a sufficient quantity of warm and weak fluids, as the common barley-water, and the like; and teas made of the common herbs of sage, mint, baum, &c. with the milder alexipharmic roots. Nothing is more likely to abate the heat, attenuate the humours, remove spasms and obstructions, promote perspiration, increase the quantity of urine, &c. in short, produce every salutary effect in an ardent or inflammatory *fever*, than drinking plentifully of water, thin gruel, or any other weak diluting liquor, of which water is the basis: the necessity of such liquors is plainly indicated by the dry tongue, the parched skin, and the burning heat, as well as by the thirst of the patient. Many cooling liquors, very agreeable to patients in *fevers*, may be prepared from fruits, as decoctions of tamarinds, apple-tea, orange-whey, &c. with these also are to be given the gentle refrigerants, such as are able to break the thick and tough consistence of the humours. Of this kind are the temperate alexipharmic roots especially,

cially, as they are alſo endowed with a diuretic virtue. Such are the roots of elecampane, pimpernel, butterbur, and the like. Scordium is alſo by ſome greatly recommended in this intention. Theſe may be conveniently given in decoctions or infuſions; and with theſe powders are to be given, compoſed of the abſterſive and digeſtive ſalts, ſuch as tartarum vitriolatum, and the like, mixed with ſuch things as have a power of obtunding and incraſſating the acrid and thin ſulphureous ſaline humours; ſuch are the abſorbent powders of oyſter-ſhells, crab's-claws, and the like. Theſe ſhould be firſt fixed with lemon juice, and then mixed with a little nitre, and with the before mentioned ſalt, they make an excellent medicine. They may be given every three, four, or ſix hours, as the urgency of ſymptoms requires, and a draught of the decoction before preſcribed given after them. The abſorbent powers have been commonly preſcribed in *fevers*; but it would be better if they were neglected. Emuſſions of ſweet almonds, and the cooling ſeeds, are alſo very proper at convenient intervals. See FEBRIFUGE.

The method of ſuppreſſing *fevers* by means of cold, now commonly adopted, was practiſed by Hippocrates, Galen, Celſus, Avicenna, and the ancients: they expoſed their patients to cold air, and they gave them cold water to drink. Nothing is more deſired by a patient in a *fever* than freſh air; it removes his anxiety, cools the blood, revives the ſpirits, and is in every view beneficial. There ought, therefore, to be a conſtant ſtream of freſh air in his chamber, ſo as to keep it moderately cool. Air that has been repeatedly breathed, when the blood is inflamed, or the humours are in a putrid ſtate, becomes unfit for reſpiration, and acquires a noxious quality. See AIR, *fever*, and BLOOD.

The medicines by which the phyſician is to aſſiſt nature in her following buſineſs of excretion, are the gentle diaphoretics, among which the diaphoretic antimony, when truly prepared, holds a very high place. The alexipharmics, which have alſo a diuretic virtue, ſuch as the mixtura ſimplex, when faithfully prepared and lightly camphorated, are very proper; and the bowels are in the mean time to be kept open by emollient clyſters. Theſe things are proper in all *fevers*; but in ſome, alſo vomits, gently laxative medicines, and bleeding, are extremely proper: theſe, however, are not to be admitted at random in all kinds.

At the beginning of a *fever*, the patient generally complains of great laſſitude or heavineſs; and this ſymptom evinces the propriety of keeping him eaſy, and, if poſſible, in bed: lying in bed relaxes the ſpaſms, abates the violence of the circulation, and gives nature an opportunity of exerting all her force to overcome the diſeaſe. The bed alone has often removed an incipient *fever*. The food of the patient in a *fever* ſhould be light, and eaſy of digeſtion, and given in ſmall quantities: it ought chiefly to be of the vegetable kind, as panada, roaſted apples, gruel, and ſuch like. All violent medicines are to be avoided in *fevers*; for nature uſually attempts to do her office placidly and quietly in theſe caſes, and ſuch medicines violently diſturb her motions, and often bring on miſchiefs which ſhe would have wholly avoided. For this reaſon, vomits, though they are by ſome given indiſcriminately in all *fevers*, are to be very cautiouſly meddled with; and there are, in reality, only a few *fevers* in which they can be allowed to be proper; for in acute legitimate *fevers*, the cauſe of the diſeaſe never lies in the primæ viæ; and the violent emotions in vomiting not only dreadfully diſturb the ſtomach and bowels, but occaſion a fulneſs of the veſſels about the head and neck, with various diſorders of the head in particular. In bilious *fevers*, the cauſe is indeed evidently in the primæ viæ; but even in theſe, it is not ſo diſpoſed as to be ſo ſafely thrown up by vomit, nor can the inflammatory ſtate of the patient at that time properly bear ſuch a violent ſhock. In intermittents, vomits are never proper, unleſs in tertians, for the cauſe in the other does not lie in the primæ viæ; and even in tertians, it may be diſpoſed to evacuation by gentler means, and without the violent tumult that a vomit occaſions in the body.

Notwithſtanding the cautions above given with reſpect to the uſe of vomits, they are in many caſes very neceſſary and beneficial on the firſt attack of a *fever*. Antimonial medicines, adminiſtered for this purpoſe, curb the circulation, and promote all the diſcharges. Their influence on the whole nervous ſyſtem is ſuch, that the ſtrength is rarely ſo much reduced when they are duly adverted to as when they are omitted.

Acrid purges are in general to be avoided in *fevers*. The proper medicines of this kind are the ſal Glauber. tart. vitr. ſal polychreſt. or Rupellenſe, tamarind. rhubarb, and manna; and if two or three grains of the emetic tartar is added in caſes that indicate a vomit to be proper, they will operate both ways, and there will be no occaſion for adminiſtering an emetic by itſelf. Bleeding, though abſolutely neceſſary in ſynochal or continent *fevers*, is not adviſable in many others; and very often the opening of a vein, and taking away too little blood, is the occaſion of congeſtions of blood in the head, whence ariſe deliriums and other dreadful ſymptoms. The ſtate of diſeaſes in this country is ſo much altered, that true inflammatory *fevers* are very rare; and that there is hardly one *fever* in ten where the lancet is neceſſary. In many caſes bleeding would be very prejudicial; and this general rule may be obſerved, never to bleed at the beginning of a *fever*, unleſs there be evident ſigns of inflammation. The giving of hot ſudorific medicines before the proper time greatly diſturbs nature, and brings on many ill conſequences. Junker's Conſp. Med. p. 261. Buchan's Med. chap. 13.

In all *fevers* the drinking plentifully of warm and cold weak liquors, is attended with many good conſequences; the patient is always refreſhed by it, the febrile heat is mitigated, reſt is promoted, and the proper and neceſſary ſweats forwarded. The ſymptoms of *fevers* are never to be ſo regarded as to prevent the due attention to the principal point, nor is the phyſician to be alarmed at them. Want of appetite, and thirſt, with long watchings, are not to be attacked with particular medicines, but looked upon as mere ſymptoms that will hereafter go off of themſelves; and inquietude of mind ſhould have no other medicine than ſerious advice of the harm it will do. Sudden cooling of the body in all *fevers* is a very dangerous thing. The patient is adviſed to ſwallow his liquids gently, not haſtily. Volatile ſalts have been with many of a long time in great uſe in *fevers*; but they are uſually attended with bad conſequences afterwards, many perſons having been thrown into ſomewhat like ſwelling of the legs and feet, and ſome into an abſolute aſcites, only by the uſe of theſe in *fevers*.

Acids in general are by many very much dreaded in *fevers*; but there is no real ground for this: on the contrary, in ſanguineous *fevers*, during the time of the violent heat and immoderate thirſt, they are found of the greateſt uſe and benefit. Spirit of vitriol, or of ſulphur, lemon-juice, with that of barberries, are all found very beneficial; only in caſes where there is a cough, the vitriolic acid is to be avoided, becauſe it uſually irritates that ſymptom, and lemon-juice ſweetened with ſugar alone is to be given. The uſe of aſtringent medicines, though too common, yet is extremely improper in all *fevers*; for in all theſe caſes the ſecretions and excretions all require to find the ways open; but theſe are all obſtructed by aſtringents, and violent ſymptoms are brought on by this means, and often death. But in ſtubborn intermittents, where the peccant matter is diſcharged, and yet theſe ſymptoms remain merely from their having become habitual, theſe aſtringents may be allowed of, and are indeed not only ſafe, but of the greateſt uſe. Junker's Conſp. Med. p. 263.

Nitre is an admirable medicine in *fevers* in general; it agrees with all temperaments, but principally with the hot; when taken in ſolution with warm and weak liquors, it always gently opens the bowels; and when given in powders, it more than all other things obtunds the acrimony of the humours.

In feverith diſorders, accompanied with hæmorrhages, the arnica vera has been recommended. See ARNICA *vera*.

The moſt general and genuine diviſion of *fevers* is into *eſſential* and *ſymptomatic*.

FEVER, *eſſential*, is that whoſe primary cauſe is in the blood itſelf, and which does not ariſe as an effect or ſymptom from any other diſeaſe in the ſolids or other parts. This is what we abſolutely and properly call a *fever*.

FEVER, *ſymptomatic*, is that which ariſes as an accident or ſymptom of ſome other antecedent diſorder; as an inflammation, phlegmon, eryſipelas, impoſthume, ſmall-pox, pleuriſy, &c.

Whence it is peculiarly denominated inflammatory, eryſipelatous, purulent, variolous, or pleuritic *fever*.

Eſſential fevers are generally diſtinguiſhed into *continued* and *intermitting*; others chooſe to divide them into *diary*, *intermittent*, *continent*, and *continued*.

FEVER, *continual*, is that which gives the patient no reſpite or intermiſſion, or which ſhews no remarkable increaſe or abatement in the ſymptoms.

This is ſubdivided by ſome into the *acute*, *ardent*, or *inflammatory*, the progreſs of which is quick, and the ſymptoms violent; the *ſlow* or *nervous*, in which theſe are more gentle; and the *malignant*, *putrid*, or *petechial*, when livid or petechial ſpots manifeſt a putrid ſtate of the humours; and by others into *putrid* and *not putrid*.

FEVER *not putrid*, *continual*, is that wherein the parts of the blood are not ſo diſſolved and broken as to give occaſion

for the principal parts thereof to be secreted; or that wherein there is not any discharge of putrid, purulent matter into the blood.

FEVER, *continued putrid*, is that wherein the texture of the blood is rendered so lax, or even dissolved, that its parts be principles separating, some of the principal of them are secreted and lost. See *Putrid* FEVER.

FEVER, *ardent* or *inflammatory*, called by the Greeks *causos*, is a very acute *fever*, generally introduced by rigor or chilness, and attended with a vehement heat, a frequent and full pulse, a pain of the head, dry skin, restlessness of the eyes, a florid countenance, pains in the back, loins, &c. difficulty of breathing, dry coughs, extreme thirst, inflammation, and commonly a rough and black tongue. The more dangerous symptoms are a delirium, laborious respiration, starting of the tendons, hiccup, cold clammy sweats, and an involuntary discharge of urine. The persons most subject to this *fever* are the young and vigorous, and plethoric; and it is most frequent in the spring and beginning of summer. It is occasioned by violent exercise, strong liquors, and a full diet with little exercise, and by any thing that obstructs perspiration, as lying on the damp ground, drinking cold liquor when the body is hot, watching, &c. This *fever* seems to have no critical time for its termination, either in recovery or in death. When it is very violent, or very badly conducted, it sometimes proves fatal on the ninth day. Persons often die from the eighteenth to the twentieth; and sometimes about the fortieth day, after having been alternately better and worse. The general course of these *fevers* is determinable from the fourteenth to the thirtieth day. The regimen proper for this *fever* should be such as is calculated to dilute the blood, correct the acrimony of the humours, allay the excessive heat, remove the spasmodic stricture of the vessels, and promote the secretions. The patient should, therefore, drink plentifully of diluting liquors, as water-gruel, clear whey, barley-water, balm-tea, &c. which may be sharpened by juice of orange, currant jelly, &c. orange whey, made by boiling in milk and water a bitter orange, sliced, or a lemon, a little cream of tartar, or a few spoonfuls of vinegar, till the curd separates, is an excellent cooling drink. Two or three spoonfuls of white wine may be added to the boiling liquor. If the patient be costive, an ounce of tamarinds, with two ounces of stoned raisins of the sun, and a couple of figs, may be boiled in three pints of water to a quart, and this liquor may be used at discretion. His diet should be spare and light, and consist chiefly of gruel, panada, roasted apples, &c. He should be relieved by the admission of fresh air into his chamber, and by sprinkling it with vinegar, lemon-juice, or vinegar and rose water, with a little nitre dissolved in it. His mouth should be often washed with a mixture of water, honey, and vinegar; and his feet and hands should be frequently bathed in lukewarm water, especially if the head be affected. To which we may add, that the patient should be kept as still and composed as possible. Bleeding should be performed as soon as the symptoms of an inflammatory *fever* appear, and repeated at the distance of twelve, eighteen, or twenty-four hours, according to the symptoms, till the hardness and fullness of the pulse are sensibly abated. Hæmorrhages, or bleedings from the nose, often occur in this *fever* much to the relief and security of the patient. If the *fever* and heat be very great, forty or fifty drops of dulcified spirit of vitriol may be made into a draught, with an ounce of rose-water, two ounces of common water, and half an ounce of simple syrup; and this draught may be administered every three or four hours, while the *fever* is violent. When the patient discovers an inclination to vomit, the efforts of nature should be assisted by weak chamomile-tea or lukewarm water. If the belly be bound, a clyster of milk and water, with a little salt, and a spoonful of sweet-oil or fresh butter in it, should be daily administered; and if this should fail, a tea-spoonful of magnesia alba, or cream of tartar, may be frequently added to the patient's drink. If about the tenth, eleventh, or twelfth day, the pulse becomes more soft, the tongue moister, and the urine begins to deposit a reddish sediment, the disease promises a favourable issue; but if, on the contrary, the spirits of the patient become languid, the pulse sinks and yet retains its hardness, and his breathing becomes difficult, accompanied with a stupor, trembling of the nerves, starting of the tendons, a swelling of the belly, wildness of the eyes, and constant raving, there is great danger. In this case blistering-plasters should be applied to the head, ancles, insides of the legs and thighs; and poultices of wheat-bread, mustard, and vinegar, may be likewise applied to the soles of the feets and the patient should be supported with cordials, as white wine whey, negus, sage-gruel with wine in it, &c. As this disease is always attended with danger, the best medical advice should be procured as soon as possible.

Inflammatory *fevers* may be distinguished into two stages; the first, while the pulse continues hard, in which it is proper to bleed; and the second, when the inflammatory symptoms still remaining, the pulse is too low for that evacuation. In this last state, blisters are the chief remedy, and which, except in a few singular cases, are not to be used sooner. If the blisters are larger it is better to apply them gradually, than many at a time. It is usual to begin with the back, and, if necessary, to apply them next to the legs or the thighs, reserving the arms last, that the patient may be so much the longer conveniently moved. There is no caution more necessary to a young physician, than to abstain from all opiates through these *fevers*, however much the patient may complain of pain in watchfulness. Indeed, if the *fever* be accompanied with a diarrhœa, which is not critical, the forefinger is to be gradually checked by discordium, after giving rhubarb, and endeavouring to turn the humours to the skin by the use of the diaphoretics, omitting the nitre, with the rest of the volatile sceouchion for the common drink. When the patient is beginning to recover, he should avoid excess of food, drink, exercise, and company, for fear of a relapse, and if his digestion be bad, and he should be troubled with feverish heats, an infusion of Peruvian bark in cold water will be of use; and when he has recovered his strength, he ought to take some gentle laxative. Buchan's Dom. *Med.* chap. 15. and Tissot's Advi.., &c. p. 244. &c. Pringle's Obs. on the Diseases of the Army. p. 134. 136.

To the class of *burning fevers* are reducible the *typria*, *ardides*, *hectics*, &c.

The *typria* is a burning *fever*, wherein the heat is very intense within-side, and at the same time the external parts are cold.

The *ardides* is a burning *fever*, attended with great inquietudes, nausea, vomiting, &c.

The *hectics* is a *fever* wherein the patient sweats continually.

The *synochal fever* is that attended with frequent sweatings.

The *epialus* is that wherein both heat and cold are felt in the same part at the same time.

FEVER, *bilious*. When a *fever* is accompanied with bilious discharges by vomit or stool, whether it be continual, intermitting, or remitting, it is called bilious, and belongs to the class of *ardent fevers*. See BILIOUS *fever*, and CHOLERIC *fever*.

Dr. Percival, in his Essays Medical and Experimental, informs us, that in these *fevers* the powder of COLUMBO root, given in doses of fifteen to twenty grains, with vitriolated tartar, from one to two scruples every four, five, or six hours, produces both speedy and beneficial effects. Dr. Haygarth of Chester further remarks, that after the primæ viæ are unloaded of their bilious contents, the columbo-root admirably allays the nausea, constantly attendant on this disorder, and that it answers our warmest wishes, by correcting the bile, restoring the proper tone of the stomach, and of the whole habit; and that it is an excellent preservative of relapses to which patients in this disorder are peculiarly disposed.

Burning bilious fever of the West Indies, called also the *yellow fever*, frequently attacks the Europeans, who indulge to excess, and are not careful to guard against the heats and dews that are common in that part of the world. It attacks with a transient chillness and shivering, which are soon succeeded by a burning heat all over the body, and more particularly about the præcordia; the pulse is high and quick, but not hard; the eyes are heavy; a violent head-ach follows, with a strong pulsation of the temporal arteries, and a laborious respiration; a nausea succeeds with bilious discharges; the anxiety of the patient is very great, and he feels pain in the back and loins, and an uneasy lassitude in the limbs. In about twelve hours after the first attack, the tongue is very dry, rough, and discoloured; the thirst is excessive, a soreness is felt all over the body, and a delirium comes on. In the last stage the patient labours under a COMA, manifests great oppression about the præcordia; at length the tendons tremble, cold sweats and convulsions terminate in death. When the patient recovers, the crisis usually happens on the fourth day after the attack, and discovers itself by a suffusion of bile all over the body; and a yellow tinge in the eyes is reckoned a favourable prognostic. Incessant vomiting, with discharges growing of a darker colour, is a fatal sign; and if a dysentery, which is a threatening symptom, accompanies an inflamed redness of the eyes, death may be expected in a few hours. Bleeding should be immediately proposed; but after the third day it is hardly advisable. Then one or two grains of tartar emetic should be given for evacuating

ating the bile; and the belly muſt be kept ſoluble by repeated doſes of ſaline purges. When the prime viæ are evacuated, the bark, either in ſubſtance or infuſed in cold water, muſt be freely uſed, in doſes as large and as often repeated as the ſtomach can digeſt them. It ſhould be given as ſoon as a remiſſion is obſerved, or a diaphoreſis is produced. The colombo-root ſhould be alſo tried. Bliſters may keep off the coma ; or if it comes on, they ſhould be applied to the head, arms, and legs, and ſinapiſms to the ſoles of the feet. Cordial medicines, with camphor, ſhould be alſo duly adminiſtered. Motherby's Dict.

FEVER, *bilioſo-catarrhal*, in *Medicine*, the name given by authors to a *fever* extremely different from the malignant one of the ſame denomination, which is alſo called by way of diſtinction, *petechialis*. This is the diſeaſe deſcribed in the writings of the ancients, under the name of *febris quotidiana continua*. It is properly a continual ſymptomatic *fever*, in which nature is labouring of herſelf to correct the vitiated lymph, whether its faults be in quality or only in motion. This is done by increaſing the ſecretory or excretory motions beyond their natural ſtandard, but yet not to any great violence. The difference between this and the malignant kind, though it very great as to make them appear wholly different ſpecies, yet is only in degree. Junker's Conſp. Med. p. 313.

Signs of it. This *fever* always attacks people in an evening, and is principally frequent in the ſpring and autumnal ſeaſons. A gravedo and coryza either preface it, or are immediately joined with it, and the patient is afflicted with a hoarſeneſs and difficulty of ſwallowing; he feels alſo a kind of inflammation, or, as it were, St. Anthony's fire within his throat, and a weight in the breaſt; and is attended through the whole courſe of the diſeaſe with a violent cough, which brings up nothing, and with a remarkable univerſal langour of the body. Pains in the back, attended with ſhiverings, frequently alſo attend the firſt attacks of this *fever*, and continue half an hour, ſometimes an hour; theſe are ſucceeded immediately by a gentle heat, and this brings on a ſeries of ſtraitneſs over the breaſt, a difficulty of breathing, and in ſome people a continual reaching to vomit. This heat endures fewer or more hours, according to the degree of the plethora. The pulſe is frequent and quick, the appetite is weak, the ſtrength fails, and the ſleep becomes unquiet and diſturbed; the head rather feels weak than painful; and ſometimes vomitings, often diarrhœas, ſoon ſucceed theſe complaints. Sweats are frequent and copious; and the urine, which is of an orange-colour, as it is in all inflammatory *fevers*, has this peculiar quality in this caſe, that it depoſits a bluiſh white ſkin, beſide the roſe-coloured ſediment.

Perſons ſubject to it. Theſe are principally thoſe of a ſanguine or phlegmatic habit, and ſuch as have a very faulty ſtream; ſuch as are intitled by their uſual occupations to expoſe their head and neck much to the cold; thoſe who have had the itch, or any other violent cutaneous eruption ſtruck in upon them; and thoſe who are watchful long in the night, and drink too much wine.

Cauſes of it. Theſe are frequently violent and ſudden cooling of the body, as when hot with exerciſe, by drinking large draughts of cold liquors; the acrid matter uſed to be thrown off by a coryza, driven back; and all things which any way impede natural and healthful perſpiration.

Prognoſtics in it. The ſimple catarrhal *fever* often goes off very happily without the aſſiſtance of medicines, only by obſerving a good regimen; but notwithſtanding this natural mildneſs, it often becomes dangerous to particular conſtitutions, and by means of improper treatment; but the more it recedes from its natural mildneſs, and the more intenſe the heat is, the greater fear there is of ſome of the viſcera being injured. The ſimpleſt event of it is by a daily reſolution and ſucceſſive diſſipation of the morbific matter.

Method of treatment. The fault of the lymph in this diſeaſe, uſually conſiſting in its viſcous and mucous textures, is to be relieved by alexipharmics, and the like medicines. The roots of elecampane, pimpernel, and viſcoſe ficaria, are famous for doing great ſervice in theſe caſes; and to theſe may very properly be added the ſaline diaſſitives, ſuch as nitre, and the tartarum vitriolatum. The mixtura ſimplex is alſo to be given in doſes of twenty-five drops, twice, or oftener in a day. The cough is to be mollified by liquorice, emulſions of ſweet almonds, oil of almonds and barley-water, water-gruel, or the like. The bowels are alſo to be gently kept open by a laxative diet, a frequent drinking of weak and emollient liquors, and by clyſters at proper times. See CATARRH.

FEVER, *malignant catarrhal*, in *Medicine*, the name of a *fever* extremely different from the ſimple *catarrhal fever*, and much more dangerous. This is alſo called by ſome the *petechial catarrhal fever*. It is a diſeaſe in which nature is endeavouring, by increaſing the ſecretory and excretory motions, to eliminate the catarrhal, acrid, and active matter. This is unqueſtionably the ſame ſpecies of *fever* with the ſimple one of this name, but extremely different in degree, and is often even epidemical. This is called by ſome the *ſcorbutic Hungarica*, and *febris inflammatoria cum petechiis*; but the latter appellation is uſed to expreſs it in its very worſt ſtate, and when attended with its moſt terrible ſymptoms. The petechiæ, or ſpots, in this *fever*, are to be carefully diſtinguiſhed from thoſe in the common ſcorbutic caſes. Junker's Conſp. Med. p. 317.

Signs of it. Theſe are the ſame with thoſe of the ſimple *catarrhal fever*; but with this difference, that in this caſe there are alſo violent anxieties of the mind, a ſudden reſolution of the ſtrength, a continual difficulty of breathing, and a loathing of all kinds of food. This laſt ſymptom uſually continues till the eleventh day. The patients are alſo ſubject to frequent faintings, and are uſually delirious, and complain of very ſharp pains in the back, and in the joints. After theſe ſymptoms the petechiæ uſually appear; theſe are little red ſpots on the breaſt, &c. reſembling flea-bites. When hot medicines are given, the petechiæ are enlarged. Aphthæ and quinſies are alſo very frequent attendants on this *fever*; and diarrhœas ſeldom fail of appearing at ſome ſtage of the diſeaſe, and are often critical.

This *fever* ſeldom attacks the patient with a ſhivering. It is very contagious in the manner of other malignant *fevers*, and has this peculiar circumſtance, that it is very often complicated with other diſeaſes, and, according to the ſeaſons and other accidents, frequently appears under their form. In February, March, and April, it often has the appearance of a pleurify; in May, and June, it often affects the ſymptoms of the *obſtructed febris*; and at this ſeaſon of the year is frequently, in the beginning, attended with terrible hæmorrhages. In July and Auguſt, a dyſentery is frequently joined with it; and in the winter months, it generally has a hot cough attending on it. Perſons of tender habits are much more ſubject to this diſeaſe than thoſe who are of a hardy and robuſt make. But as it is contagious, it ſometimes ſpares no age, ſex, or conſtitution, that comes in the way.

Cauſes of it. The moſt frequent cauſes of this diſeaſe are a fermentaceous and putrid exhalation in the air, and the contagium from the bodies and effluvia of the ſick: and in the laſt caſe, a natural terror of receiving the infection is often found to make people more ſubject than ordinary to receive it. And to theſe are to be added the eating of vitiated and fermenting proviſions, and the ſudden cooling of the body when very hot with labour or exerciſe, and frequent and violent paſſions ſuppreſſed.

The ſpots which appear on certain days in this diſeaſe are not eſſential to it, though common; and hence the *fever* is rather called by accurate writers, *febris petechizans*, than *petechialis*; they are a relief to the patient, if they are not violently repelled, or ſome other way improperly treated. When they appear earlier than the ſeventh day, they are alſo obſerved to be worſe preſages than when they appear on, or after it. When the ſpots appear in very great numbers, they uſually fly back again, and the patient is much endangered by it. And when they are of a bright red, and after three or four days ſpace once go off again, and leave the patient better than before, they are a ſure good prognoſtic. But if they are of a livid or black colour, they are a very bad omen; and when after the eruption the perſon does not find himſelf relieved, the conſequence is often a miliary purple *fever*. Lightheadedneſs before the ſeventh day is leſs dangerous than it if does not happen till after it. Diarrhœas in all other eruptive *fevers* are a very bad ſymptom, and often preſage the death of the patient. But that is not the caſe in this; they ſometimes prove critical, and carry off the diſeaſe. But when that is not the caſe, they are of no bad effect, and are always better for the patient than an obſtinate coſtiveneſs. But it is to be obſerved, that though theſe diarrhœas, when they come naturally, are of great relief in many caſes, and of no harm in others; yet are it not here to be uſed as nature, and no purging medicines are by any means to be given to bring on a laxity of the bowels.

Method of cure. Gentle evacuations are to be brought on by ſuch medicines as encourage perſpiration, and promote urine. Abſorbents, ſaturated with acids, as crab's-eyes, ſteeped with lemon-juice, are of ſervice, and to theſe ſhould be joined a ſmall quantity of nitre. Cooling emulſions are alſo to be given at times; and ſpirit of vitriol, camphorated, is to be rubbed on the head to allay the violent head-ache. And Stahl greatly recommends

commended, in the case of a too violent diarrhœa, the use of powders made of purified nitre and mountain cryſtal. In caſes of obſtinate coſtiveneſs, cliſters muſt be injected as often as is found neceſſary; and when there is a complaint of ſoreneſs in the fauces, and difficulty of ſwallowing, alſtringent gargariſms are to be uſed. Junker's Conſp. Med. p. 322. See HOSPITAL *fever*, and *Putrid* FEVER.

FEVER, *choleric*, in *Medicine*, the name of a *fever*, called alſo by ſome BILIOUS *fever*, and by others a *cauſus*; though the generality of writers diſtinguiſh the *cholerica febres* from the *cauſus*. All bilious *fevers* are properly ſpecies of acute *fevers*, and owe their origin to diſtemperatures of the bile, at times when the aliments are in a ſtate of fermentation in the ſtomach and inteſtines.

The *cauſus* is diſtinguiſhed from the *cholerica febris* properly ſo called, by its being ever much more violent and dangerous, and by the excretions which attend it. For in the *choleric fever* the vitiated gall and other bilious excretions are always plentifully voided, ſometimes upwards, ſometimes downwards, and ſometimes both ways. In the *cauſus*, the matter is more uſually detained with the body, and rarely voided otherwiſe than by vomiting, and that uſually only in ſmall quantities, and in the beginning of the diſeaſe.

Signs of it. The general ſigns of the *cholerica febris* and *cauſus* are a remarkable anxiety, and frequent complaints about the breaſt, as of a ſtraitneſs and painful heat. A violent heat on the inſide of the mouth, and inſatiable and intolerable thirſt, trembling and convulſive motions of the joints, and violent deliriums. Dryneſs of the mouth and tongue is often ſo terrible in this diſeaſe, that the ſkin cracks with it; and often the whites of the eyes, ſometimes the whole body, become yelloweſt. The peculiar and appropriated ſymptoms of a *cholerica febris*, ſtrictly ſo called, are an univerſal langour and debility of the limbs.

A ſevere ſhivering firſt ſeizes the patient, and is ſoon ſucceeded by a very violent heat and raging pain in the head; and after the two firſt days, there uſually are very terrible ſtrainings and reachings to vomit. The matter brought up at theſe times is cauſtic, acrid, and bilious, and inflames, and even ulcerates the fauces, and if voided upon a ſtone floor, effervеſces violently. If this vomiting abates, there immediately comes on a diarrhœa, attended with a teneſmus, occaſioned by the irritation of this ſharp matter in the rectum. Faintings alſo are very frequent in this diſeaſe, eſpecially where the vomitings do not bring up a ſufficient quantity of the offending matter. The peculiar and appropriated ſigns of the *cauſus*, ſtrictly ſo called, are theſe; a violent and inſatiable thirſt, greater than that in any other *fever*. The bowels are always bound; and it is but very ſeldom that there is any tendency to vomit. The urine is reddiſh and turbid, and after ſtanding ſome time, depoſits a red ſediment. Often there is a ſenſible pain and ſoreneſs in the præcordia, to that the patient cannot bear the leaſt touch upon the breaſt; and uſually, in the courſe of the diſeaſe there are faintings and violent convulſions.

Perſons moſt ſubject to this diſeaſe are ſuch as eat largely, and drink heavy and imperfectly fermented liquors after it. The *cholerica febris*, properly ſo called, is moſt frequent with thoſe of a cholerico-ſanguineous habit, and ſuch as feed on high-ſeaſoned meats, and drink abundance of wine or other ſtrong liquors; and is often brought on ſuch perſons by their falling into a violent paſſion after a full meal. The *cauſus* peculiarly attacks the people of melancholic habits, who are much inclined to paſſion, but ſuppreſs it, and who are naturally coſtive.

Prognoſtics in it. The ſimple *choleric fever* is attended with great danger, if not timely undertaken to be cured. But the *cauſus* is yet more fatal than it; and from Hippocrates's days has been accounted among the *febres ineluctatæ*, or *fevers* that very frequently kill the patient.

In many *fevers* nature is able to help herſelf, and ſucceeds beſt of all when left alone. But theſe are of that number of diſtempers in which the aſſiſtance of art is abſolutely neceſſary, and out of which nature very ſeldom brings the patient ſtrictly when unaſſiſted. The happieſt turn this *fever* can take, is the copious diſcharge of the peccant matter by vomit; for when it goes downward, the febrile heat always increaſes, and the ſymptoms in general uſually grow worſe. When the reachings are violent, and the matter brought up is but ſmall in quantity, then the patient is uſually ſubjected to painful hiccups, and dangerous ſyncopes and convulſions. When much bile is thrown up by vomit, and that not very badly coloured, and there is no diarrhœa, there is then little danger from the diſeaſe; and in general, coſtiveneſs in this ſtate of the diſeaſe is more eligible than a tendency to ſtools. The more violent the delirium is in theſe diſeaſes, and the longer continued, always the greater is the danger to the patient. And if the pains and burning heat ſuddenly ceaſe, and a ſhivering and dejection of the ſpirits ſucceed, there is no doubt of a gangrene being coming on within. Junker's Conſp. Med. p. 332. 333.

Method of cure. The cure of theſe diſeaſes conſiſts in mitigating the violent ſharpneſs of the humour, and promoting its evacuation: and finally, in abating the burning heat brought on by it. The utmoſt endeavours are firſt to be made to correct and alter the morbific matter. To this purpoſe, the ſeveral preparations of nitre, with the teſtaceous powders and mucilaginous priſans, with ſmall mixtures of lemon-juice, and frequent draughts of cooling and diluting liquors, are to be given moderately warm. If the coſtiveneſs be too violent, cliſters of broth muſt be injected, with the addition of a little oil and ſalt; and, if neceſſary, ſmall doſes of rhubarb. To quell the febrile heat and emotion of the blood, the mixture ſimplex may be given with great ſucceſs; and there is often a ſenſible good effect from the application of rags wetted in camphorated ſpirit of wine to the pit of the ſtomach. After the morbific matter is evacuated, the reachings to vomit may be allayed by gentle opiates. All hot medicines change the BILIOUS *fevers* into inflammatory ones; and the common ſudorifics drive the morbific matter into the blood, and uſually bring on almoſt immediate diſcolourings of the ſkin like thoſe of the jaundice. Bleeding, though performed ever ſo early in the diſeaſe, ſeldom does any good, except only in remarkably plethoric habits.

FEVER, *colliquative*, are thoſe wherein the whole body is conſumed and emaciated in no long time; the ſolid parts, with the fat, &c. melted down, and carried off by a diarrhœa, ſweat, urine, &c.

FEVER, *continent*. See SYNOCHUS.

FEVER, *deparatory*. See DEPURATORIA *febris*.

FEVER, *diary*, is that which does not ordinarily hold beyond twenty-four hours. It is the gentleſt of all *fevers*; is frequently got by too much exerciſe, or other external accidents. It is cured by reſt alone, and keeping in bed. If it remain for ſeveral days, it is either called a *continual ephemera*, or *ſimple ſynochus*.

FEVER, *epidemic*. See EPIDEMIC, *Peſtilential* DISEASES, PLAGUE, &c.

FEVERS, *eruptive*, are thoſe which, beſide the ſymptoms common to other *fevers*, have their criſis attended with cutaneous eruptions. Such are thoſe of the ſmall-pox, meaſles, the petechial, the purple or ſcarlet *fever*, and the miliary *fever*; the other ſymptoms are a grievous oppreſſion of the breaſt, laborious ſhort breath, obſtinate waking, ſpaſms, ſore throat, cough, &c.

FEVER, *gool*. See HOSPITAL *fever*.

FEVER, *hectic*, is a ſlow, durable *fever*, which extenuates and emaciates the body by inſenſible degrees. See HECTIC and CONSUMPTION.

It has three ſtages; the firſt, while it conſumes the juices of the body; the ſecond, when it exhauſts the fleſhy ſubſtance of its humidity; and the third, when it lays hold of, and deſtroys the ſolids themſelves; in which laſt ſtage it is reputed incurable. Its effect is ſomewhat like that of a flame, firſt conſuming the oil of the lamp, then the moiſture of the wick; and laſtly, the wick itſelf. But this *fever* is frequently conſidered as of the *ſymptomatic* or *ſecondary* kind, ariſing in phthiſes, &c.

FEVER, *inflammatory*. See *Ardent* FEVER.

FEVER, *intermitting*, is that which ceaſes and returns again alternately at ſtated periods, and is called alſo an AGUE. Agues are occaſioned by effluvia from putrid ſtagnating water. They are alſo produced by eating too much ſtone-fruit, by a poor watery diet, damp houſes, evening dews, lying on the damp ground, watching, fatigue, depreſſing paſſions, and the like. In a word, whatever relaxes the ſolids, diminiſhes the perſpiration, or obſtructs the circulation in the capillary or ſmall veſſels, diſpoſes the body to this diſeaſe.

In this kind of *fever*, cold and heat, ſhivering and ſweating, ſucceed each other; the paroxyſms are attended with ſickneſs, nauſeas, vomiting, head-ach, pain in the back and loins, &c. The paroxyſms are acute, but the diſeaſe uſually more or leſs chronical.

Sometimes the diſeaſe comes on ſuddenly, when the perſon thinks himſelf in perfect health; but it is more commonly preceded by liſtleſſneſs, loſs of appetite, and the other ſymptoms above recited. The quality of the urine after the fit characteriſes theſe ſeveral ſpecies of intermittents: it is of a reddiſh colour, and lets fall a ſediment exactly reſembling brick-duſt. It is ſometimes frothy, and a pellicle or thin frothy ſkin appears on the top, and adhering to the ſides of the glaſs in which it is contained.

While the fit continues, the patient ought to drink freely of water-gruel, orange-whey, weak chamomile-tea; or, if

if his spirits be low, small wine-whey, sharpened with the juice of a lemon. His drink should be warm; and if twenty or twenty-five drops of laudanum be put into his drink, and given about half an hour after the commencement of the hot fit, it would promote his sweat, shorten the fit, relieve the head, and tend greatly to remove the disease. His food between the paroxysms should be nourishing, and easy of digestion; and his drink be small negus, acidulated with the juice of lemons or oranges, and sometimes a little weak punch. Moderate exercise will also be of great use.

In the cure of an *intermitting fever*, when it does not go off without medicine, the first object is to cleanse the stomach and bowels; for this purpose vomits should be taken before any other medicine; a scruple or half a dram of the powder of ipecacuanha will be sufficient for an adult, which may be taken two or three hours before the return of the fit, and repeated at the distance of three or four days during the operation, the patient should drink plentifully of weak chamomile-tea. If he be afraid to take a vomit, he must in this case cleanse the bowels by a dose or two of Glauber's salts, jalap, or rhubarb. At the beginning of an *intermitting fever*, when excessive heat, a delirium, &c. indicate an inflammation, bleeding may be proper: the intermittents that prevail in cold dry springs are sometimes blended with an inflammatory disposition; but the autumnal *fevers* are frequently combined with a principle of putrefaction, in which case bleeding would be improper: as the blood is seldom in an inflammatory state in *intermitting fevers*, this operation is rarely necessary.

After proper evacuations, the patient may safely use the Peruvian bark, which by the general consent of physicians, is allowed to be a specific for these *fevers* in all seasons, ages, and constitutions. Two ounces of the powder may be divided into twenty-four doses, and made into bolusses with syrup of lemon, or mixed with red-wine, chamomile-tea, water-gruel, or any other liquor that is most agreeable to the patient. In a quotidian *fever*, one of these doses may be taken every two hours during the interval of the fits. In a tertian ague, it will be sufficient to take a dose every third hour, and in a quartan every fourth. A smaller quantity of bark will suffice for a young person; and the dose must be adapted to the age, constitution, and violence of the symptoms. The patient should persist in the use of this medicine till the disease is entirely overcome; and especially in autumnal or winter agues, which are much more obstinate than those of spring and summer. A cup of the following infusion drank three or four times a day will greatly promote the cure: take an ounce of gentian root, half an ounce of calamus aromaticus, and as much orange peel, with three or four handfuls of chamomile-flowers, and a handful of coriander seeds; bruise them together in a mortar, and use them in form of an infusion or tea. About half a handful of these ingredients may be put into a tea pot, and a pint of boiling water poured on them; or two handfuls of the same ingredients may be put into a bottle of white-wine, and a glass of it may be drank twice or thrice a day. Those who prefer a decoction of the bark, may boil an ounce of it with two drams of bruised snake-root, and an equal quantity of salt of wormwood, in a quart of water till it is reduced to a pint: to the strained liquor may be added an equal quantity of red wine, and a glass of it taken frequently. In obstinate agues, and particularly unfavourable circumstances, it will be necessary to mix with two ounces of the bark half an ounce of Virginian snake-root, and a quarter of an ounce of ginger, or some other warm aromatic; but when the symptoms are of an inflammatory nature, the aromatics may be omitted, and half an ounce of salt of wormwood or salt of tartar may be added to the above quantity of bark. When children are afflicted with this disease, the bark may be rendered more palatable by mixing it with distilled waters and syrup, and sharpening it with the elixir or spirit of vitriol. It may be also given in the form of a clyster. Dr. Lind recommends for an adult half an ounce of the extract of bark dissolved in four ounces of warm water, with the addition of half an ounce of sweet-oil, and six or eight drops of laudanum, to be repeated every fourth hour, or oftener, as occasion shall require. The quantity of extract and laudanum must be diminished for children. Children have been sometimes cured by wearing a waistcoat with powdered bark quilted between the folds of it; by bathing them frequently in a strong decoction of the bark, and rubbing the spine with strong spirits, or with a mixture of equal parts of of laudanum and the sapenaceous liniment. Professor Bergman, in his Opuscula Physica & Chemica, 1779, mentions several instances in which the most obstinate *intermittent fevers* that have raged in Sweden for some years past, and that would not yield to the bark, have been almost constantly removed by the artificial Seltzer-water, or other simple impregnations of water with fixed air. The following preventative will be of service to those who live in low marshy countries, or who are liable to frequent attacks of this disease: take an ounce of the bell bark, Virginian snake-root, and orange peels of each half an ounce; bruise them all together, and infuse them five or six days in a bottle of brandy, Holland's gin, or any good spirit; pour off the clear liquor, and take a wine-glass of it twice or thrice a day. Gentian root, or calamus aromaticus may also be chewed for the same purpose: all bitters, especially those that are warm and astringent, are antidotes to agues. Buchan Dom. Med. chap. 14. and Tissot's Adv. &c. chap. 18. § 230.

In *intermitting fevers*, it seems, from Dr. Langrish's experiments, that the inflammation of the blood is not so viscid and tenacious, neither is the serum so viscous, saline, and acrid, as in acute continual *fevers*. The red globules abound more, and the crust is more viscid and tough in quotidians than in remittents, and in tertians than in quotidians. Med. Theor. and Pract. of Phys. p. 229.

The cold bath has been prescribed with success as a strengthener to those who were recovering from obstinate *intermitting fevers*, to prevent a return of the disease. See Dr. Huxham's Obs. de Aere & Morb. Epid.

Intermitting fevers are of divers kinds, as the QUARTAN, QUOTIDIAN, *double* QUOTIDIAN, and TERTIAN. There are also *intermitting fevers* which only return every fifth day, or every sixth, or every seventh, and at other intervals.

FEVER, *putrid*, *febris putrida*, in *Medicine*, a name given by Hoffter to a peculiar species of acute *fever*, pushed over in silence by the generality of authors, but by some called the *adynamic fever*, and by our Sydenham the *new fever*, *nova febris*. This differs from other acute *fevers*, in that it is attended always with a diarrhœa, which, however, is salutary, and which it is very dangerous to stop; and in that it is not relieved by the sweating or diaphoretic medicines useful in other *fevers*, much less by the hot sudorifics; all these things exasperate and make it worse; and the only things that give relief in it are gentle cathartics, and vomits that operate without violence. This *fever*, therefore, evidently shews the error of those hasty reasoners, who declare, that all acute *fevers* are to be cured by diaphoretics.

This peculiar species of *fever*, though unknown to many of the late writers, and called by Sydenham a new distemper, was not unknown to the ancients. Hippocrates has left many things concerning it; as have also the later Greeks, and Celsus; and among the moderns, Duret, Sennertus, Foreſtus, Riverius, Etmuller, Bohivi, Stahl, Hoffman, and Lancisi, have all met with it, though they have given but very short and imperfect descriptions of it in their writings.

The generality of those who have written of this *fever*, have referred it to the malignant kinds, from its being usually attended with severe and uncommon symptoms from the beginning, or from such being brought on in the course of an irregular treatment. The common method of curing *fevers* by diaphoretic medicines brings on in this, anxieties and straitnesses of the precordia, with pains about the stomach, loss of appetite and delirium, with efflorescences of various kinds, particularly petechial spots; and these symptoms are not unfrequently attended with death. But it is to be observed, that diseases are to be carefully distinguished in their own symptoms; those which the physicians brings on being often very different from what nature would offer.

These *fevers* have their seat in the stomach and *intestines*; or if they have it any where else, it appears at least that their origin, which is in a putrid colluvies, is always much more easily educed and evacuated by these than by any other passages. Many of the distempers mentioned by authors under peculiar names, are properly to be referred, as to their causes, to this species of *fever*. The dysenteric *fever* is absolutely of this kind, and many of the petechial ones. The catarrhal *fevers* also are referable to this kind; and the continual quotidian and tertian, with the *fevers* described by the ancients under the names of *hemitritæus*, *assidua*, *hectica*, *ephialtes*, and *typhus*, with the *tritophæa*, nearly allied to the *hemitritæi*, and by some authors confounded together, the words being used as synonymous.

Symptoms of intestinal fevers. These are frequent shiverings when the patient is first seized with the distemper, which return at different and irregular intervals. After these, the tongue, teeth, and fauces, are covered with a foul and viscid phlegm, the tongue, in particular, often looking yellowish and blackish with it; the patient perceives a continual disagreeable taste in his mouth

from this, and the people who are about him an ill smell. There is always a diarrhœa attending these *fevers*, and the fæces voided in it have a peculiarly offensive smell. The hypochondria are always distended, and often in pain; the patients are attended with violent tremblings in their sleep, so that they are frequently waked in terrors and uneasiness, and in tenderer subjects, these also are very frequent while waking. Pains in the head and neck are also constant attendants of this distemper, and seem to take their origin from spasms. The urine, in the beginning of the disease, is of a natural state and colour, and afterwards becomes turbid, and deposits a muddy sediment during the whole course of the distemper.

These are the constant symptoms of these *fevers*, but beside these, there are sometimes other violent ones, such as violent anxieties of the præcordia, pains in the stomach, and in the side resembling those of a pleurisy, a loss of strength, a violent internal heat, and a continual convulsive or tremulous motion of the hands, with a subsultus tendinum, hiccough, and cold sweats; which are extremely dangerous symptoms, and presage a fatal period to the distemper.

Beside these, which are the common, and the additional symptoms of these *fevers*, there are yet some others often seen in them, which are merely accidental, and are owing to the improper management of the patient. It is a common error to give hot and sudorific medicines in these cases; the consequence of which is, that the peccant matter which was lodged before in the primæ viæ is propelled into the blood, and not being able to make its way through the pores, it appears under the skin in form of petechiæ or purple spots, or of papulæ of a purple or reddish, sometimes of a livid or blackish colour. Under this circumstance, which is wholly owing to the ignorance of the prescriber, the distemper gets the name of a petechial or a purple *fever*. Sometimes the same methods send the matter to the ears, where it occasions deafness; sometimes to the parotids and maxillary glands, where it forms tumors, inflammations, and abscesses of a very bad sort; and finally, if it be transferred to the brain, violent deliriums and a phrenitis are the certain consequence. Thus, according as this matter happens to be driven by this improper treatment to a more or less noble part of the body, it gives the symptoms of a more or less dangerous disease; and very frequently the patient seems to have a pelurisy or peripneumony, or an inflammation in the liver, spleen, or intestines, while in reality the cause of the disease is all the while the same; and there is no difference but that of the matter's settling on one or another part. Heister's Compend. 2fed. p. 83. and 97.

The method of cure. All hot medicines must be avoided, and the discharge of the peccant matter by the diarrhœa promoted by clysters, and by purging medicines. Some advise aloes, and other medicines of that kind; others sena and manna; some the purging salts; but most prefer rhubarb, given in often repeated small doses. Large draughts of the lubricating decoctions, such as barley-water and water-gruel, are to be given, and emulsions of sweet almonds and of the cold seeds. Small quantities of oil of sweet almonds are also to be given at times, and juleps of the cooling waters and syrups moderately acidulated, and powders of nitre, cinnabar, and the common absorbents, as crabs-eyes and the like, are to be given, to take off the pains and spasms, and to attemperate the acrid matter. Bleeding in this *fever* is not necessary, unless in plethoric habits; and in these cases it must be done on the access of the disease; for if done after the third or fourth day, it is usually found to do more harm than good.

The diet in these *fevers* is not to be so very thin and weak as in other acute *fevers*, but moderate nourishment is to be allowed, that the patient may retain his strength sufficiently to go through it: in the beginning of the disease, however, the patient has usually an aversion for food, and then it is not to be forced upon him; but when the stomach begins to require it, then it is to be given in a moderate quantity; and great care must be taken that nothing astringent or difficult of digestion be allowed, but light and innocent meats, and with these a little good wine to promote digestion. Some also have given frequent vomits, by small doses of ipecacuanha in these *fevers*, with very good success; and it is remarkable, that the purple *fever*, mentioned by Stahl and others, as peculiarly affecting lying-in women, and being very frequent in Saxony for a long time, was by Dr. Wagner and others cured by this method: its origin being found to be a viscous matter putrefying in the stomach and intestines; and therefore, the distemper being properly one of these *intestinal fevers*, was curable by the same methods with them; that is, by emptying the primæ viæ.

Some, as Baglivi and Bachard, have called these *fevers* *mesenteric fevers*; but improperly, according to Heister, lib. c. p. 85.

FEVER, *malignant*, are those in which the danger is much greater than the symptoms indicate, or in which the usual regular symptoms do not appear (nature being oppressed with the malignity of the *febrile* matter), but other foreign symptoms arise; as a pain about the stomach, and præcordia; a livid complexion, with the face much disfigured, &c. and sometimes efflorescences on the skin, &c.

Some authors, from microscopical observations, affirm, that in all *malignant fevers*, the blood is so corrupted, that swarms of little worms are generated therein, which occasion most of the symptoms.

In all *malignant fevers* the blood is too fluid. Bleeding has here no place; cineties do well at first, afterwards sudorifics and alexipharmics: blisters are commended in the progress of the disease. See *Malignant catarrhal* FEVER, *Miliary* FEVER, *Putrid* FEVER, and HOSPITAL *fever*.

FEVER, *mesenteric*. See *Intestinal* FEVER.

FEVER, *miliary*, or *purple*, an acute, continued, exanthematous *fever*, in which nature seems to be endeavouring to drive out the subtle morbific matter to the surface of the body, by increasing her secretory and excretory motions. It takes its name from the small pustules or bladders, &c. which appear on the skin, resembling in shape and size the seeds of millet.

This *fever* is divided into two kinds; of the which, one is called *purpura rubra*, or the *red purple fever*; and the other by a very odd form of expression, the *purpura alba*, or *white purple fever*.

The *white purple fever* is usually malignant; it is easily complicated with the petechial *fevers*, and in some places has of late years been found often to affect lying-in women. The *red purpura* is much more benign and mild than this, and indeed often is attended with no danger.

These two species of *purpura* seem to differ as much as the small-pox and measles do from one another, the white *fever* of this kind being usually as much more fatal than the red, as the small-pox is more fatal than the measles; but as there are cases in which the small-pox is mild and benign, and the measles are sometimes dangerous, so in these diseases, out of the natural course, the white is sometimes mild, and attended but with a slight *fever*, while the red is fatal, and attended with a very high one. As the small-pox also has white pustules, and the measles only protuberances on the skin, so the *white purple fever* has also white regular pustules, while the red has only such protuberances as those of the measles.

The *miliary fever* is sometimes a primary disease; but it is much oftener a symptom of some other malady, as the small-pox, measles, ardent, putrid, or nervous *fever*; and in all these cases it is the effect of too hot regimen or medicines.

Signs of this disease. The white kind seizes the patient with a general shivering and coldness, and straitness of the præcordia, with great anxiety of mind, a low, quick pulse and loss of strength; and afterwards shews itself in alternate changes of heat and cold; and before the appearance of the eruptions, the patients are worse in respect of their anxiety and other symptoms; they are very restless, and sometimes delirious; the tongue appears white, the hands shake, attended frequently with a burning heat in the palms; and in child-bed women the milk generally goes away, and the other discharges stop; and they complain of a troublesome pricking or itching under the skin. The pustules usually first appear on the third or fourth day, sometimes later; and at their approach, there is first perceived a general redness of the skin; and after this the redness is collected into spots, in the middle of each of which there appears a white pustule; and these are often so copiously spread over the body, that they almost touch one another. These pustules are pellucid, and contain only a clear water, afterwards they grow yellowish; in child-bed women they are sometimes interspersed with pustules of a red colour: when these appear, the disease is called a rash; and their eruption is usually attended with an acute *fever*; when these pustules have stood four days, they dry away, and the places appear scaly, and the disease terminates. Sometimes, in people of humid habits, and such as have no *fever*, these pustules sweat out a white water.

The *red purple fever* seizes the patient in nearly the same way with the white; that is, with shiverings and heat succeeding one another. It is also attended with a tension and pain in the back, and with a straitness of the breast and a cough. The *purple* eruptions appear on the fourth, or on the seventh day, or later even than that, in form of small protuberances like millet seeds, and are attended at the time of their eruption with an itching within

within the skin: they are moſt numerous when the ſweat is moſt abundant, as on the breaſt, back, &c. though the whole body is ſometimes covered with them: the *fever* is not violent; and the ſweat is copious, and of an ill ſmell. In ſome caſes this diſeaſe is attended with no *fever* at all, and people go about their buſineſs with it, only complaining of an itching all over them. Some have violent pains of the head at the time, and are unaccountably ſleepy and anxious; but theſe ſymptoms uſually go off as ſoon as the eruptions appear properly; theſe remain fully out a few days, and then die away of themſelves and the perſon finds himſelf as well as before. The *purple fever* of both kinds ſeems to have been more frequent of late than in the times of the earlier writers on medicine. The white kind in particular, ſome years ago, was in a manner epidemic in Saxony, and carried off great numbers, and particularly ſeized the lying-in women. Wherever the petechial *fevers* are frequent, there the white *purple fever* is uſually alſo common. It often alſo mixes itſelf with the ſmall-pox, and makes the caſe always greatly the worſe, and all the ſymptoms more violent. The red *purple fever* is moſt frequent with young men, and ſuch as lead ſedentary lives, and are ſubject to violent paſſions; labouring people are ſcarce ever found affected with this diſeaſe. Among women, thoſe of tenderer conſtitutions are moſt ſubject to it, and eſpecially ſuch as have been before ſubject to hyſteric complaints. And the perſons moſt ſubject of all to it are thoſe of both ſexes who live at eaſe and within doors, and by this means always are ſending off the humours to the ſurface of the body.

Cauſes of it. Theſe are a bad quality in the air, contagion from perſons who have the diſeaſe, the driving back of ſweats, and even the forcing them too violently by hot medicines: this too often happens to women in child-bed, and to perſons in petechial *fevers*. To theſe are to be added alſo, the curing of the rheumatic and catarrhal diſorders by a too cold regimen and method, and an omiſſion of habitual bleedings, or by ſuppreſſion of the menſes, or diſcharges by the hemorrhoidal veins. The *miliary fever* is ſometimes occaſioned by violent paſſions and emotions of the mind; by great evacuations, a weak watery diet, rainy ſeaſons, exceſſive uſe of cold, crude, unripe fruits, impure waters, and unwholeſome proviſions. In child-bed women this diſeaſe is often the effect of great coſtiveneſs during pregnancy, and of immoderate uſe of green trafh, &c. But the more general cauſe is indolence.

Prognoſtics in it. The going back of the eruptions in the white *purpura* is very often fatal, and in the mildeſt circumſtances is uſually attended with ſphacelations of the mind, and terrible anxieties; and if by means of medicines the eruptions appear again, and yet the ſymptoms occaſioned by their going in do not diſappear, there is great reaſon to ſuſpect danger. The white *purpura* attending the petechial *fever* is very dangerous when the eruptions appear on the fourth day, but is leſs ſo when they appear later. The white *purpura* when not attended with a *fever*, is leſs dangerous than otherwiſe; but it is uſually attended with diſtreſſing anxieties of mind, and with ſpaſtic motions.

The red *purpura*, when the eruptions are ſtruck back, is not attended with ſuch ſudden danger as the white; but people uſually have ſome convulſive motions attending it, and a great languor and debility of motion, and ſometimes inflammations of the fauces, and dangerous quinſeys; ſometimes a dry cough, ſometimes a heat of urine, or aſthmic complaints, or a ſpurious pleuriſy, or a hemicrania; but all theſe ſymptoms go off as ſoon as the eruptions appear again.

If a diarrhœa comes on in the progreſs or decline of the diſeaſe, and is ſuddenly checked, it endangers an apoplexy. In child-bed women a diarrhœa is a very dangerous ſymptom; and the change of the colour of the urine from a yellow to a pale-colour is alarming; ſleepineſs is a favourable ſymptom.

Method of cure. This is to be the ſame both in the red and the white *purpura*, and is not different from that in other inflammatory *fevers*; namely, a gentle, but continual perſpiration muſt be kept up, and this alone will often cure the diſeaſe.

The patient's food ſhould be weak chicken-broth with bread, panada, ſago, or groat gruel, &c. to a gill of which may be added a ſpoonful or two of wine. If his ſpirits are moderately high, his drink ought to be weak, as water-gruel, baum-tea, &c. a decoction of two ounces of the ſhavings of hartſhorn, and the ſame quantity of ſaſſaparilla in two quarts of water, ſweetened with white ſugar, may be uſed as his ordinary drink. When the ſpirits are low, wine-whey or ſmall negus, ſharpened with the juice of orange or lemon, ſhould be allowed. If the *fever* has a putrefcent tendency, the patient's ſtrength muſt be ſupported with generous cordials joined with acids; and if the putreſcence increaſe, the bark muſt be adminiſtered. When the head is affected, the body ſhould be kept open by emollient clyſters.

On the days before the eruption of the *ſpots*, powders are to be given of nitre, diaphoretic antimony, and the abſorbents, as crabs-eyes, and the like; and when the eruptions are out, which uſually happens on the fourth day, the ſame powders muſt be given interchangeably, with gentle ſudorific draughts; from all which, ſumitory-water, however, is to be carefully excluded. When the eruptions appear and return, camphor ſhould be added to any other medicines. The moſt proper cordial in this caſe is good wine, and the medicines ſhould be of the cordial and perſpirative kind; and all heating ones ſhould be avoided. A vomiting and diarrhœa, which ſometimes attend this diſorder, are mitigated by the ſaline draughts with ſaffron and crabs-eyes. This method is to be continued, only giving the doſes leſs frequently in the decline of the diſeaſe; and when it is wholly gone off, gentle purges are to be given thoroughly to cleanſe the primæ viæ, and the patient is by degrees to be hardened to the air. It is to be obſerved, that all irritations of the bowels are as bad in theſe caſes as in the ſmall-pox or meaſles, and that even the uſe of the moſt gentle clyſters ſhould be very ſparingly admitted. Bleeding can very rarely, if ever, be proper in this diſeaſe, as it commonly ſeems to be more of a putrid than of an inflammatory nature. Bliſters may be uſed through the whole courſe of the *fever*; but they ſhould be ſmall, and one applied at a time. However, if the pulſe ſhould ſink remarkably, the puſtules fall in, and the head be affected, it will be neceſſary to apply ſeveral bliſtering-plaſters to the moſt ſenſible parts, as the inſide of the legs and thighs, &c. People who are often ſubject to returns of the red or white *purpura*, would be right to uſe cupping with ſcarification frequently, by way of prevention; and when the cauſe of the diſeaſe is the ſuppreſſion of ſome habitual evacuation, great care is to be taken to ſupply the place of that by bleedings, if it cannot be recalled in the accuſtomed way. This is to be done at different times to prevent relapſes; and in general, a method of uſing gentle exerciſe, ſo as to promote a moderate ſweat, is greatly preferable to the method uſed by ſome of clothing too warm, which rather promotes the diſeaſe, by inviting the humours to the ſurface.

Pregnant women ſhould guard againſt coſtiveneſs, uſe regular exerciſe, avoid all green trafhy fruits, and other unwholeſome things; now and then take a gentle laxative of manna or rhubarb, or cream of tartar, and bleed in the firſt months; and when in child-bed, ſtrictly obſerve a cool regimen. Junker's Conſp. Med. p. 327, and 329. Buchan's Dom. Med. chap. 21.

FEVER, *milk*. See MILK.

FEVER, *nervous*, called alſo *ſlow fever* and *fever on the ſpirits*, attacks perſons of a weak relaxed habit, who neglect exerciſe, eat little ſolid food, ſtudy hard, or indulge in ſpirituous liquors. This *fever* may be occaſioned by any thing that depreſſes the ſpirits and impoveriſhes the blood, as anxiety and grief of mind, watching, intenſe thought, poor and irregular diet, unripe fruits, damp and unwholeſome air, exceſſive evacuations, wet cloaths, great fatigue, and whatever obſtructs the perſpiration and cauſes a ſpaſmodic ſtructure of the ſolids. The preſaging ſymptoms of a *nervous fever* are low ſpirits, want of appetite, laſſitude, watchfulneſs, ſighing, and dejection of mind; theſe are ſucceeded by a low, quick, and unequal pulſe; a dry tongue, without any conſiderable thirſt; alternate chillneſs and flothing; giddineſs and pain in the head; naufea and vomiting; pale urine, reſembling dead ſmall beer; difficult reſpiration, and ſlight alienations of mind. If in the progreſs of this *fever*, towards the ninth, tenth, or twelfth day, the tongue and ſkin become moiſt, with a plentiful ſpitting and gentle purging; or if a ſuppuration happens in ear or both ears, or large puſtules break out about the lips and noſe, a favourable criſis may be expected; but the more dangerous and alarming ſymptoms are an exceſſive looſeneſs, walling ſweats, with frequent fainting fits; a trembling tongue, when put out, cold of the extremities and a fluttering of low creeping pulſe, a ſtarting of the tendons, an almoſt total loſs of ſight and hearing, and an involuntary diſcharge by ſtool and urine. The patient in this diſeaſe ſhould be kept cool and eaſy, his ſtrength and ſpirits muſt be ſupported by nourriſhing diet and generous cordials; and therefore wine ſhould be mixed with his gruel, panada, &c. and ſtrong wine-whey or ſmall negus, sharpened with the juice of orange or lemon, or muſtard-whey, will be proper for his ordinary drink. Wine that is good and genuine is a very neceſſary and effectual medicine in this *fever*; patients have been recovered from the moſt dangerous ſtate by uſing in whey, gruel,

gruel, and negus, a bottle or two of strong wine every day. If a nausea prevail at the beginning, a gentle vomit should be given; and if the symptoms continue, it may be repeated any time before the third or fourth day. Those who cannot take a vomit should have their bowels cleansed by a small dose of rhubarb, or an infusion of senna and manna. Bleeding is generally improper in this disease, but blistering is highly necessary; blistering-plaisters may be applied to all parts of the *fever* with great advantage; and if the patient be delirious, he ought to be blistered on the head and neck. Glisters, however, are most proper towards the beginning, or after some degree of stupor comes on, in which case it will be always proper to blister the head. A stool should be procured every other day by a glister of milk and water, with a little sugar; if worms may be suspected, a spoonful of common salt. As violent loudness, should it happen, may be checked by small quantities of Venice treacle, or by giving the patient for his ordinary drink the white decoction. If a miliary eruption happen, as it sometimes does about the ninth or tenth day, it should neither be checked by bleeding and other evacuations, nor pushed out by a hot regimen. In desperate cases, large doses of musk may be frequently repeated; or fifteen grains of musk, with three grains of camphire, and six grains of salt of hartshorn, may be made into a bolus, with a little syrup, and given three or four times a day. In the intermission of the *fever*, the patient should take half a dram, or a whole dram of bark in a glass of red port or claret, four or five times a day. The bark may also be administered with other cordials, in the following manner: take an ounce of Peruvian bark, half an ounce of orange peel, two drams of Virginian snake-root, and one dram of saffron; let them be powdered and infused for three or four days in a pint of the best brandy; drain the liquor, and give two teaspoonfuls of it three or four times a day in a glass of small wine or negus. Buchan's Dom. Med. chap 19. Edinb. Med. Ess. vol. iv. p. 280. vol. vi. p. 28.

FEVER, *peripneumonic*. See PERIPNEUMONY.

FEVER, *pestilential*, are acute, contagious, and mortal diseases. Some will have the *fever* to be the disease or plague itself, others only account it a symptom of the plague. See *Epidemical* DISEASES, PLAGUE, *Putrid* FEVER, &c.

FEVER *petechial*, is a malignant *fever*, wherein, beside the other symptoms, on the fourth, or more frequently on the seventh day, petechiæ, or red spots, like flea-bites, appear chiefly about the shoulders, breast, and women; the spots afterwards turn pale, then yellow, and so disappear. When they grow livid or black, they usually prove fatal.

This *fever* is contagious, and often epidemical. See *Malignant catarrhal* FEVER, and *Putrid* FEVER.

FEVER, *puerperal*, or *childbed fever*, is that to which women are subject in the time of pregnancy, and more especially in their lying-in: it generally makes its attack on the second or third day after delivery. The proximate cause of this disorder is an irritability and inflammation of the abdominal viscera, and principally of the intestines and the omentum; and the remoter causes are a sudden emptying of the womb, in consequence of which the blood rushes into the emptied membranes with an impetuosity that often excites inflammation; coagulated blood lodged in the uterus after delivery, obstructed lochia, a putrid air, accefs of the milk, inflammation of the breasts, absorption of acrid milk, and retention of the excrements. But the chief predisposent cause of the inflammation of the intestines and omentum in lying-in women to which this *fever* is owing, is the constantly increasing pressure of the gravid uterus against these viscera during the latter months of gestation, and in the time of labour; the ill effects of which are *aggravated* by occasional causes occurring after delivery, particularly by keeping the patient hot and costive, and giving her warm spices and spirituous cordials. This *fever* comes on like most others, with a cold or shivering fit, which is succeeded by restlessness, pain of the head, great sickness and bilious vomiting. The pulse is quick, the tongue dry, the spirits deprefsed, and strength weakened. A great pain is commonly felt in the back, hips, and region of the womb; a sudden change takes place with respect to the quantity or quality of the lochia; and the patient is frequently troubled with a tenesmus: the urine is very high-coloured, and discharged with pain, and in small quantity. The belly sometimes swells to a considerable size, and is always sore and tender. When the *fever* has continued for a few days, the symptoms of inflammation usually subside, and the disease acquires a more putrid form. A bilious or putrid diarrhœa, of an obstinate and dangerous nature, comes on, and accompanies the disease through its future progress. In women of plethoric constitutions bleeding will be generally proper at the beginning; but it should be used cautiously, and not repeated, unless the symptoms of inflammation rise highly, in which case a blistering plaister may also be applied to the region of the womb. During the cold fit the patient should drink warm diluting liquors, and warm applications to the extremities of the body, as of heated bricks, bottles or bladders of water, &c. may be used with advantage. Emollient clysters of milk and water, or of chicken-water, should be frequently administered through the course of the disease. Sometimes a vomit is given for evacuating the bile from the stomach; but it will be safer to substitute a gentle laxative; the saline draught is proper to be repeated for this purpose, and if it runs off by stool, or if the patient be restless, a few drops of laudanum, or some syrup of poppies may be added: if the stools should be so frequent as to exhaust the patient, a starch clyster, with thirty or forty drops of laudanum in it, may be used; and her drink may be rice-water, with half an ounce of gum arabic dissolved in every pint; and if these fail, recourse must be had to the columbo-coot, or some other astringent. Dr. Hulme lays the principal stress in this disorder on the free and repeated use of purgative medicines, such as the sal cathartices, and cream tartar, or the tartarus emeticus, or vinum antimoniale, given in small doses every two or three hours, till an effectual discharge is procured; in consequence of which, he says, that the patient generally finds an immediate relief from pain, kind sweats come on, gentle slumbers succeed, and the pulse becomes more calm and slow. When this disorder has arrived at the putrid state, antiseptics should be used; and particularly the bark, in decoction or infusion, mixed with tincture of roses, or other gentle astringents; a couple of the extract of bark, with half an ounce of spirituous cinnamon-water, two ounces of common water, and ten drops of laudanum, may be made into a draught, and given every second, third, or fourth hour. For a prevention of this *fever*, women in child-bed should be kept very easy; their food should be light and simple, and their bed-chamber clean, cool, and properly ventilated. To this circumstance of introducing fresh and cool air into the chamber of the patient Dr. Hulme ascribes his never having observed any petechiæ, exanthemata, or any febrile eruptions attending this *fever*, nor a single influence of the *miliary* FEVER in the London lying-in hospital, where he has attended more than 1400 women after delivery. Buchan's Dom. Med. p. 387, &c. Hulme's Treatise on the Puerperal Fever, 1772.

FEVER, *putrid*, is a general denomination, under which may be comprehended the plague, spotted or petechial *fevers*, pestilential, malignant, camp, gaol, &c. These are various names of the same kind of disease, according to the degree in which it prevails, or the different circumstances that attend it. Those who are most subject to this *fever* are persons of a lax habit, cold or phlegmatic constitutions, and a melancholy disposition, or who are weakened by watching, falling, poor or luxurious diet, hard labour, excessive venery, &c.

The remote causes of this disease are a stagnated and foul air, rendered noxious by putrid animal and vegetable effluvia; and, therefore, it prevails in camps, hospitals, gaols, large populous close towns, and low marshy countries; warm, sultry weather, with a moist atmosphere; unwholesome diet, as corrupted grain, putrid flesh or fish, and when that is become putrid by stagnation; a long continuance of animal food without a proper mixture of vegetables, whence sailors in long voyages, and the inhabitants of besieged cities are peculiarly subject to this *fever*; and an excessive use of alkaline salts and other medicines that dissolve the blood. The proximate cause is a dissolution of the blood, produced by putrid miasmata that are received into the lungs by inspiration into the stomach with the food, or being generated in some part of the body, are absorbed, as from putrid ulcers, &c.

The symptoms of the accefs of this *fever* are a remarkable weakness of body without any apparent cause, and dejection of mind. These are succeeded by nausea, and sometimes a vomiting of bile; a violent pain of the head, with a strong pulsation or throbbing of the temporal arteries; inflammation of the eyes, with a pain in the bottom of the orbits; noise in the ears; difficult respiration, accompanied with sighing; pain in the back and loins, and region of the stomach; the tongue at first appears white, but afterwards livid and black; and the teeth are covered with a black crust. The urine, from being pale, becomes more highly coloured, and at last is very brown and blackish, and has more or less an offensive smell; the stools are extremely fœtid, and are sometimes of a greenish, black, or reddish cast. Livid spots appear on the skin; and there are sometimes violent hæmorrhages

or discharges of blood from the mouth, eyes, nose, &c. Patients in this disorder void worms both upwards and downwards, are affected with tremors, and become delirious.

Putrid *fevers* may be distinguished from the inflammatory by the smallness of the pulse, the great dejection of mind, the dissolved state of the blood, the petechiæ or purple spots, and the putrid smell of the excrements. They may be distinguished from the low or nervous *fever* by greater heat and thirst, by the higher colour of the urine, and by the greater violence of the symptoms. In some cases the inflammatory, nervous, and putrid symptoms are combined; and *fevers* of the inflammatory and nervous kind, by improper treatment, are converted into malignant and putrid ones. This *fever* seems to have no critical time for its termination; sometimes it terminates between the seventh and fourteenth day, and at other times is prolonged for five or six weeks.

The favourable prognostics are a gentle looseness after the fourth or fifth day, a warm mild sweat, small miliary pustules appearing between the purple spots, hot scabby eruptions about the mouth and nose, the rise of the pulse after the use of wine and other cordials, the abatement of the nervous symptoms, abscesses in the groin or parotid glands, and within the ears occasioning deafness towards the decline of the *fever*. The unfavourable prognostics are an excessive looseness, with a hard, swelled belly, large black or livid blotches, aphthæ in the mouth, wild staring of the eyes, blindness, change of the voice, difficulty of swallowing, an inability to put out the tongue, a constant inclination to uncover the head, cold clammy sweats, bloody sweat and saliva, black urine that deposits a black foetid sediment, starting of the tendons, and foetid, ichorous, involuntary stools, attended with a coldness of the extremities.

The regimen and medicines proper for patients in this *fever* are such as counteract the putrid tendency of the humours, support their strength and spirits, and assist nature in expelling the cause of the disease, by promoting perspiration and the other evacuations. For this purpose they should be provided with a circulation of fresh air; and their apartments should be sprinkled with vinegar, lemon-juice, or any other vegetable acid: fumigations of myrrh, and other aromatic and antiseptic ingredients, may be used; and strong scented herbs, as rue, tansy, wormwood, &c. may be dispersed in different parts of the house, both for the relief of the sick, and for preventing the infection. The food should be light, as panada, &c. mixed with red wine, and sharpened with acids; and the drink should be orange, lemon, or vinegar-whey, with the addition of wine in such quantity as the patient's strength requires; acidulated negus, or chamomile tea sharpened with elixir of vitriol or Clutton's FEBRIFUGE spirit. If the patient be costive, a tea-spoonful of cream of tartar may be put into a cup of his drink, or he may drink a decoction of tamarinds. The strength and spirits of the patient should be supported by frequently taking small quantities of proper aliments. If he be delirious, the hands and feet should be often fomented with a strong infusion of chamomile flowers, or of the bark.

Bleeding is seldom necessary, but often hurtful in putrid *fevers*; and in cases where there are evident signs of inflammation in the beginning of the disease, it should be very cautiously admitted. The first medicine proper to be prescribed in this *fever* is an antimonial emetic, the operation of which may be succeeded by a dose of the julep of camphor. Small doses of the emetic tartar may be repeated every second or third hour, with proper antiseptics and cordials; the safest and best cordial is good Rhenish or red wine; and one of the most powerful antiseptics is the Peruvian bark, which should be given early in this disorder, unless symptoms of inflammation should appear and regularly continue. An ounce of the powder may be mixed with half a pint of water, and the same quantity of red wine, and sharpened with the elixir of spirit of vitriol; to which may be added two or three ounces of syrup of lemon; and two table-spoonfuls of this mixture may be taken every two hours, or oftener. Those who cannot take the bark in substance may infuse it in wine. If a diarrhœa comes on, the bark should be boiled in red wine, with a little cinnamon, and sharpened with the elixir of vitriol, or gentle opiates and astringents may be used. Plenty of acids and medicines that promote a gentle perspiration are very beneficial in this kind of looseness. If the patient be troubled with a vomiting, a dram of the salt of wormwood dissolved in an ounce and a half of fresh lemon juice, and made into a draught, with an ounce of simple cinnamon water and a bit of sugar, may be given and repeated as often as it is necessary. Blisters are generally useful in the early stages of these *fevers*; when the petechiæ or spots suddenly disappear, the pulse sinks, and a delirium approaches, they may be applied to the head and inside of the legs or thighs; but when there is any reason to apprehend a gangrene from the use of blisters, warm cataplasms of mustard and vinegar may be applied to the feet. When the glands swell, as they sometimes do in this disease, the suppuration of the swelling should be promoted by the application of poultices, and at a proper time they should be laid open, and the poultices continued. Ulcerous sores, of a livid appearance and putrid smell, that break out in the decline of this *fever*, may be gradually healed by the plentiful use of Peruvian bark and wine, sharpened with the spirit of vitriol.

Opening and antiputrefcent clysters, and mild laxative medicines, are proper to be administered during the progress of this disease. Camphor is useful both as an antispasmodic and antiseptic, particularly in the beginning of putrid *fevers*. *Fixed air* is a very efficacious antiseptic; and the introduction of it into the materia medica, in consequence of the experiments and discoveries of Dr. Macbride, Dr. Priestley, and others, promises to be of great use in a variety of disorders, and especially in those of the putrid kind. Mr. Hey of Leeds, in the year 1772, administered it with great success in a dangerous case of the putrid kind, by impregnating the water which his patient drank with fixed air from the atmosphere of a large vat of fermenting liquor, and by injecting clysters of it, collected from a fermenting mixture of chalk and oil of vitriol. Dr. Percival of Manchester has also found the efficacy of fixed air in wines, &c. impregnated with it, for checking the septic ferment, and sweetening the putrid colluvies of the prime viæ in malignant *fevers*. Dr. Dobson of Liverpool, and Dr. Watren of Taunton, have likewise made successful trials of this medicine in putrid disorders. Dr. Hulme has successfully prescribed fixed air in cases of the gout, hectic *fevers* with consumption, putrid *fevers*, dysentery, and worms: he makes use of no particular apparatus for impregnating water and other liquors with this air; but he does this by the mere mixture of two liquors; these liquors are the solution of fixed alcaline salt and water, containing as much vitriolic acid as he finds, *a priori*, to be sufficient to neutralize the alkali, and to expel from it all its fixed air. He gradually and cautiously mixes these with each other, so as to prevent the effervescence or the dissipation of the fixed air as much as possible. His usual mixture consists of fifteen or thirty grains of salt of tartar dissolved in three ounces of water; to which are added three ounces of water properly acidulated by means of the vitriolic acid. In putrid *fevers* he also recommends half a dram of salt of tartar dissolved in three ounces of Peruvian bark, with the same addition of acidulated water as before. Hulme's Safe and Easy Remedy for the Stone, &c. 1778. See PYRMONT *waters*.

Mr. Magellan, in a letter to Dr. Priestley, recites a remarkable instance of the efficacy of fixed air thus administered in a putrid *fever* by a physician in Holland; the decoction of bark, which had been tried without effect, was afterwards mixed with the salt of tartar and vitriolic acid, and in three days the bad symptoms were removed, and the patient soon recovered. Prince Galitzin, the Russian ambassador to the States of Holland, has found by analysing the bark, that it contains a large quantity of fixed air; and to this quality he conjectures the antiseptic virtues of it may be owing. Priestley's Exp. and Obf. in Nat. Philof. &c. 1779. p. 372.

Dr. Priestley's *nitrous* AIR, which is a more powerful corrector of putrefaction than fixed air, may be found on trial to be of still greater service. For preventing putrid *fevers* a ſtrict regard to cleanlineſs, a dry ſituation, ſufficient exerciſe in the open air, wholeſome food, and a moderate uſe of generous liquors, may be recommended. The infection alſo ſhould be carefully avoided; and a perſon who is apprehenſive of having caught it, ſhould immediately take a vomit, and work it off by drinking plentifully of chamomile tea; and uſe for his ordinary drink an infuſion of the bark and chamomile flowers, with ſtrong negus, or a few glaſſes of generous wine.

Sir John Pringle obſerves, that the plague, and other peſtilential *fevers*, hot ſcurvies, and dyſenteries, have very much abated in Europe within the laſt century; a bleſſing we can aſcribe to no other ſecond cauſe more than to the improvement of every circumſtance relating to cleanlineſs, and to the more general uſe of ANTISEPTICS. In regard to diet too, it may be obſerved, that hopped beer, wine, and ſpirituous liquors, coming more into general uſe, have been a great means of ſuppreſſing putrid and malignant diſeaſes. Greens and fruit are likewiſe more commonly uſed, and ſalted meats make a much leſs part of diet than they did formerly. To which may be added the more general conſumption of tea and ſugar, which are no inconſiderable antiſeptics. With reſpect to the contagious nature of all putrid diſorders, he thinks that the putrid effluvia received into the blood have a power of corrupting the whole maſs: of which

he conceives the refolution of the blood, and fometimes even its fmell in the advanced ftate of a malignant *fever*, the offenfiveneſs of the ſweats and other excretions, the livid ſpots, blotches, and mortifications incident to this diſtemper to be ſufficient proofs. By the acrimony of theſe effluvia, the nerves are affected with various ſpaſms, the pulſe is always quickened, at firſt raiſed, and ſoon depreſſed. Buchan's Dom. Med. chap. 20. Prieſtley's Exp. and Obſ. on different Kinds of Air, vol. i. Appendix, vol. ii. Ap. Pringle's Diſeaſes of the Army, p. 293, 298, &c. Pargeye's Enquiry into the Cauſes, Symptoms, and Cure of putrid *Fevers*. See BILIOUS *fever*, HOSPITAL *fever*, &c.

FEVER, *remitting*, called alſo a *continual fever*, *συνοχος*, and a *compound continual fever*, is that which continues ſome time without any gradual increaſe of heat, yet is liable to alternate fits of remiſſion and aggravation, either ſtated and periodical, or irregular.

Of this there are divers kinds, denominated from the periods of returning, as the *remitting*, *continual quotidian*, *continual tertian*, *continual quartan*, &c. which are only a continued *fever*, whoſe acceſſes or feverer fits return every day, or every other day, or every third day, or every fourth day.

Some enumerate divers other more complicated continual *fevers*; as the *double* or *triple quotidian*, which has two or three paroxyſms every day; the *double* or *triple tertian* or *quartan*, which have two or three every third or fourth day; the *ſemi-tertian*, by the Greeks called *hemitritæus*, which conſiſts of a *continual*, and two *intermitting fevers*, of different kinds, viz. a *quotidian* and *tertian*; the patient, beſide a *continual fever*, having an extraordinary fit every day, and every other day two.

Others divide the *remitting*, *συνοχος*, or *compound continual fever*, into *ſimple* and *ſpurious*.

The *ſimple remitter* returns regularly, and is only diſtinguiſhed from an intermitter in that the ſeveriſh heat in the interval of this latter is never quite extinguiſhed; and that the paroxyſms do not begin with ſo much chilline's and horror, and go off in profuſe ſweats.

The *ſpurious remitter* is attended with grievous ſymptoms of the nervous kind, reſembling thoſe of the rheumatiſm, colic, pleuriſy, and other inflammatory and ſpaſmodic diſeaſes; beſide immoderate exertions, vomitings, diarrhœas, &c. whence its returns are uncertain and variable.

The *ſimple* rarely, if ever kills; the *ſpurious*, frequently: ſometimes it degenerates into a malignant *συνοχος*.

The firſt is cured with the cortex Peruv. almoſt as infallibly as an intermitter: when it is brought to a regular intermiſſion by bleeding, if there be ſigns of inflammation; or by a vomit, which may be repeated if the naufea continues, and by clyſters or gentle laxatives: the febrile ferment being much the ſame in both, and the ſame medicine is found almoſt a cure, though not ſo ſpeedy a remedy of the ſpurious, if properly applied. The diet and medicine in theſe *fevers* muſt be regulated by the predominant ſymptoms, whether they be inflammatory, nervous, or putrid. Whatever is of a heating quality ſhould be avoided, as this *fever* is frequently changed into a continual one by a hot regimen and improper medicines.

Theſe *fevers* prevail in low marſhy countries abounding with wood and ſtagnating water; but they prove moſt fatal in places where great heat and moiſture are combined, as in ſome parts of Africa, the province of Bengal in the Eaſt Indies, &c. where they are generally of a putrid kind, and prove very fatal. The moſt likely way to avoid the *remitting fever*, is to uſe wholeſome and nourihing diet, to pay the ſtricteſt regard to cleanlineſs, to keep the body warm, to take ſufficient exerciſe; and in hot countries to avoid damp ſituations, night air, and evening dews. Where it is epidemical, the beſt preventive medicine is the bark, which may be chewed or infuſed in brandy or wine, &c. Buchan's Dom. Med. chap. 22.

FEVER, *ſcarlet*, the name of an eruptive *fever* uſually attacking young perſons, and not attended with any great danger. When it is moderate in degree, it may be left to nature alone, and will go off very well without aſſiſtance of medicines, only obſerving a good regimen; but if it be more violent, it is to be treated with more care: the patient is to be kept warm in bed, and to be made to drink large quantities of warm diluting liquors, acidulated either with lemon juice or ſpirit of ſulphur or vitriol, and draughts of the attemperating and diluting medicines are to be given every four or ſix hours, together with the attemperating and gently diaphoretic powder; but during the courſe of the cure all hot things are to be carefully avoided, as well in food as medicine, for every thing of this kind renders the diſeaſe worſe, when treated in the proper manner. The *ſcarlet* ſpots, after a few days, dry off, and the ſkin ſcales away, and after this the patient uſually is ſoon well. At this time two or three doſes of ſome gentle purge are to be given; and if the weather be bad, the patient is to be confined to his chamber for ſome days afterwards, that the tranſpiration may be free and uninterrupted; by this means the worſt kinds of this *fever* go well off.

But when this caution is neglected, it is very common to find the patient fall into a ſwelling of the belly after about three weeks, and ſometimes into an anaſarca; ſometimes attended with a *fever*, ſometimes without one, and often with tumors of the glands, and many other dangerous diſorders. The urine in theſe caſes becomes brown and turbid, and many are loſt in this manner. But as this new diſeaſe, as it is uſually called, though it is in reality no other than another period of the *ſcarlet fever*, owes its whole origin to the morbific matter which cauſed the firſt appearance of that, being in part retained in the body, the beſt method of cure is by thoſe remedies which are able to carry thoſe humours out of the body. Gentle purges are to be given at ſhort intervals, and the way nature indicates is to be carefully followed, by giving diuretics in the intermediate days; for the brown turbid urine voided naturally in this caſe is an attempt of nature to carry off the matter that way. The beſt of all diuretics in this caſe is a tincture of ſalt of tartar and ſpiritus nitri dulcis mixed together, and taken twenty drops or more three times a day. In young ſubjects, who will not take purges in the common way, a clyſter made of an infuſion of ſena purges them very well, and anſwers the purpoſe.

The common hot ſudorifics are not to be given in theſe caſes, for ſweat is ſcarce to be obtained by any means in this diſeaſe: and great care is to be taken to keep the tumid parts from the cold air, otherwiſe the patient is often carried off at once by the chilling of them. If there be a *fever* with this ſecond complaint, as is uſually the caſe, the attemperating medicines are to be given in an afternoon and evening, and draughts of gently diuretic liquors to be drank after them.

In this, and in all other eruptive *fevers*, any thing that cools the patient is of the utmoſt conſequence, and the bed is not to be new made, nor the ſhirt changed by any means during the courſe of the diſtemper. Immoderate heat, on the other hand, is almoſt as bad, and the middle regimen is the only proper one to be obſerved. The patient lying quiet, and being kept in an equal and moderate heat in all caſes of eruptive *fevers* as well as in this, may be allowed in the beginning to walk about in his chamber, taking great care to keep out the cold, and need not be confined to his bed ſo long as his ſtrength will permit his keeping up. Heiſter's Compend. Med. p. 83.

FEVERS, *ſlow*, are gentle, but durable ones: they conſume the patient by degrees. They uſually ariſe from diſorders in the lympha or pituita, whence Sylvius calls them *lymphatic fevers*.

The principal of theſe are the catarrhal, attended with a catarrh, cough, hoarſeneſs, &c. and the ſcorbutic *fever*, into which acute *fevers*, and ſometimes intermittent kinds degenerate. See *Nervous* FEVER and HECTIC.

The *ſlow fever*, or *febris lenta*, properly and diſtinctly ſo called, differs from the hectic *fever* in its origin; for it is generally produced by the degeneration of diary *fevers*, ſynochæ, or quotidians improperly treated, and by the common intermittents violently and injudiciouſly ſuppreſſed by aſtringents: but the hectic *fever* is connected with the terrible accidents of vomicæ, empyemas, and apoſtemations inflammations of the viſcera. Nor do they differ leſs in the continent cauſe; for in the *ſlow fever* there is not yet any actual hurt in the viſcera, but only a tendency toward it, and ſuch a diſpoſition as may naturally bring it on; but in the hectic there is always either an obſtinate ſcirrhus or an apoſtem, or a ſimple or ſiſtulous ulcer. Junker's Conſp. Med.

The ſymptoms of theſe diſeaſes differ alſo as much as their cauſes; for in the *febris lenta* they are all mild, and in the hectic all terrible and violent. The *febris lenta* never is ſo violent a diſeaſe as to confine the patient long to his bed, and uſually grows milder in the continuance than at firſt; but on the contrary, the hectic ever grows worſe by duration; and finally, the *febris lenta* in all caſes, except where it ariſes from the improper uſe of aſtringents in intermittent caſes, is attended with profuſe ſweats; whereas the hectic, unleſs when urged by medicines of a wrong kind, is a dry heat, and never throws out any ſweats till in the laſt ſtages. In *ſlow fevers* of this kind, the ſtools are thin, and not frequent, and uſually have a mucous matter mixed with them. In the hectic, when complete, there uſually come on violent diarrhœas, which carry off the patient. The *lenta febris* is ſubject to degenerate into other diſeaſes, and frequently

returns

returns into the diſtemper, from which it firſt aroſe; but the hectic is ſubject to no tranſmutations. And finally, the *lenta febris* often goes off happily of itſelf, nature making her way through the obſtruction, and completing the cure. The hectic is uſually fatal.

Signs of the febris lenta. Theſe are a preternatural heat often ſcarce ſenſible to others, but very troubleſome to the patient; a dryneſs of the mouth, and continual thirſt; a loſs of appetite, and waſting of the ſtrength; a general dullneſs of the face, except for a ſluſhing of the cheeks; a waſting of the fleſh; violent ſweats in the night; and a redneſs and foulneſs of the urine when firſt made, but afterwards a precipitation of a pale, red ſediment, and the remainder then is clear above.

Perſons ſubject to it. Theſe are principally young men who are of a plethoric habit, and who have had an ephemera or ſynocha, or ſome other *fever* of that kind, improperly treated with too hot medicines; and ſuch as in *fevers* of other kinds, where nature produced copious ſweats, have ſuppreſſed them either by medicines or by an improper regimen; and finally, people worn down and exhauſted by violent hæmorrhages.

Progreſs in it. This kind of *fever*, when it ariſes from an intermittent, and, in fine, returns into its old ſtate again, is attended with very little danger; but there is much more danger where it continues long in its own appearance, or where it degenerates, as it too frequently does, into an acute one. The degeneracy of this *fever* into a hectic, is of all other conditions of it the moſt dangerous; and this is not always readily diſtinguiſhed; this is, it may be ſuſpected, the caſe when the patient's appetite returns, and yet all the ſymptoms continue; eſpecially if there be added to them a ſhort cough, and difficulty of reſpiration; and when there is a ſenſation of a weight in the abdomen, and it is painful to lie otherwiſe than on one ſide, or in ſome particular poſture.

Method of cure. The firſt thing to be done is to attempt the reſolving of the ſtaſis, as by pimpernel and cleſcampe roots, by the gentle alexipharmics, and by the neutral ſalts, as the tartarum vitriolatum, and the like. The viſcid foulneſſes left by intermittent *fevers* are to be carried off by firſt attenuating and inciding them by the gums, as ammoniacum and the reſt; and the tone of the viſcera is to be finally re-eſtabliſhed by the gentler chalybeats and ſtomachics.

When the caſe ariſes from an acute *fever*, powders of tartar of vitriol, crabs-eyes, and diaphoretic antimony, with gentle cathartics in the intermediate days, will often complete a cure; when it ariſes from an intermittent, no happier means can be deviſed for the cure than the bringing it back to its old ſtate of the intermittent again. Etmuller ſays, that the volatile alkalis, ſuch as ſpirit of ſal ammoniac, have a great power this way; and Stahl propoſes to effect it by an habitual drinking an infuſion of elecampane, pimpernel, centaury, orange-peel, and ſena, with a ſmall quantity of rhubarb and black hellebore, in wine.

Finally, when this caſe has been brought on by violent hæmorrhages, the analeptics alone are to be depended upon, with the teſtaceous powders, to abate the ſweats, and the lighter tinctures of ſteel to reſtore the loſt tone of the ſolids. Junker's Conſp. Med. p. 384.

It is obſerved in the Periodical Eſſays of Edinburgh, that in the flow *fevers* which prevailed in and near that place, November 1731, attended with a violent pain in the head, a ſmall quick pulſe, deliriums, and watchfulneſs; ſeveral of the elder ſort died, but of the younger, many voided worms, and recovered. See Med. Eſſ. Abridg. vol. i. p. 66.

FEVER, *ſtationary*. See STATIONARY.

FEVER, *tanſy*. See DENTITION.

FEVER, *yellow*. See *Burning bilious* FEVER.

FEVER, in the *Manege*, is a diſorder to which horſes are very ſubject from a variety of cauſes. The ſymptoms which denote the horſe to be afflicted with a *fever* are great reſtleſſneſs, by reaſon of which he ranges from one end of the rack to another, beating of the flanks, redneſs and inflammation of the eyes, a parched and dry tongue; his breath is hot, and of a ſtrong ſmell; he loſes his appetite, and nibbles his hay without chewing it, and is frequently ſmelling to the ground; he dungs often, but little at a time; and his dung is uſually hard, and in ſmall pieces; he ſometimes ſtales with difficulty, and his urine is highly coloured; he is always craving for water, and drinks often, but little at a time; and his pulſe beats full and hard, fifty ſtrokes and more in a minute. The firſt part of the cure is bleeding; and the quantity, if the horſe is ſtrong, and in good condition, ſhould be two or three quarts: then give him four times a day a pint of the following infuſion: take baum, ſage, and chamomile flowers, each a handful; an ounce of liquorice root, ſliced, and three ounces of nitre; and pour on theſe ingredients two quarts of boiling water; when cold, ſtrain it off, and ſqueeze into it the juice of two or three lemons, and ſweeten it with honey; or an ounce of nitre mixed into a ball with honey may be given thrice a day inſtead of the drink, and waſhed down with any ſmall liquor. The horſe's diet ſhould be ſcalded bran in ſmall quantities, or dry bran ſprinkled with water, or a handful of picked hay may be put into his rack. His water ſhould be a little warmed, and given to him often, and in ſmall quantities; his covering ſhould be moderate. If the horſe refuſes to feed, in a day or two more blood ſhould be taken away, and the drinks continued, to which may be added two or three drams of ſaffron. If his dung continues hard and knotty, a clyſter may be given, prepared by boiling two handfuls of marſhmallows, one of chamomile flowers, and an ounce of fennel-ſeed, in three quarts of water, till it be reduced to two, and adding to the ſtrained liquor four ounces of treacle, and a pint of linſeed oil, or any common oil. This clyſter ſhould be repeated every other day; and on the intermediate day the following drink may be given: take of cream of tartar and of Glauber's ſalts, of each four ounces; diſſolve them in barley-water, and add an ounce or two of lenitive electary, or a dram or two of powder of jalap. By purſuing this treatment the horſe will begin to recover; and nothing more will be found neceſſary than to give him gentle exerciſe in the air, and plenty of clean litter in the ſtable. There is another *fever* to which horſes are ſubject, more dangerous than the former: this is a ſlow *fever*, attended with great depreſſion; the horſe is ſometimes inwardly hot, and outwardly cold, and at other times hot all over; his eyes appear moiſt and languid; his mouth is continually moiſt, ſo that he has no inclination to drink, and he is ſatisfied with very little. He eats little, moves his jaws in a feeble looſe manner, and grates his teeth; his body is commonly open, his dung ſoft and moiſt; his ſtaling irregular, ſometimes little, and at other times profuſe, and his urine pale, with little or no ſediment. Theſe *fevers* are attended with a running at the noſe, and the matter diſcharged is of a reddiſh or greeniſh duſky colour, and of a conſiſtence like glue. About three pints of blood ſhould be firſt taken away, and bleeding repeated according to the ſtrength and fulneſs of the horſe, the degree of his cough, or any tendency to inflammation. After this the nitre drink already preſcribed may be given, with the addition of an ounce of ſnake-root, and three drams of ſaffron and camphor diſſolved in a little ſpirit of wine.

The horſe's diet ſhould be ſcalded or ſprinkled bran, and the beſt hay, with which he ſhould be fed by hand, as he ſometimes cannot lift up his head to the rack. Drinking plentifully will greatly contribute to dilute the blood; but if the *fever* ſhould increaſe, balls of contrayerva root, myrrh, and ſnake-root, powdered, of each two drams; ſaffron, one dram; mithridate or Venice treacle, half an ounce, mixed with honey, ſhould be immediately given twice or thrice a day, with two or three horns of infuſion of ſnake-root ſweetened with honey; to a pint and a half of which may be added half a pint of treacle water or vinegar: if theſe balls produce no ſenſible effect, let a dram of camphor or of caſtor be added to each of them; or the following drink may be ſubſtituted in their ſtead for ſome days: take a dram of camphor diſſolved in one ounce of rectified ſpirit of wine; then gradually pour on a pint of diſtilled vinegar warmed, and give it at two doſes. If the horſe ſhould be coſtive, recourſe muſt be had to clyſters or the opening drink; and if he purges to a conſiderable degree, diaſcordium may be added to his drinks inſtead of the mithridate. The operation of medicines in this diſeaſe is much promoted by plentiful drinking: the horſe's ſtaling ſhould be reſtrained when it is conſiderable and weakening, by proper aſtringents, or by mixing lime-water with his drinks; and when he is remiſs in this reſpect, and ſtales ſo little as to occaſion a ſwelling of his body and legs, two or three of the following balls may be given at proper intervals, with a decoction of marſhmallows ſweetened with honey: take of ſal prunella or nitre, one ounce; juniper-berries and Venice turpentine, of each half an ounce; and make theſe ingredients into a ball with oil of amber. If with this treatment the horſe's ſkin feels kindly, his ears and feet are moderately warm, his eyes briſk and lively, his noſe becomes clean and dry, his appetite increaſes, he lies down well, and ſtales and dungs regularly, there is a fair proſpect of a ſpeedy recovery: but he ſhould be fed ſparingly, and his diet ſhould be light, and increaſed by degrees as he gains ſtrength.

If the *fever* ſhould intermit, give an ounce of Jeſuit's bark in the interval of the ſtaſis, and repeat it every ſix hours till the horſe has taken four or ſix ounces. Bartlet's Farriery, and Farmer's Dictionary.

FEVER-

FEVER-*root*, *trifolium*, in *Botany*. See *Folia* IPECACUANHA.

FEVER-*wood*. See ERYNGO.

FEVERFEW, *Matricaria*, in *Botany*, a genus of the *frutescentes polygamia superflua* clafs. Its characters are thefe: it hath a compound flower; the ray or border is compofed of female half-florets; and the difk, which is hemifpherical, of hermaphrodite florets: the female half-florets are tongue-fhaped, are indented in three parts at the end, and have a naked germen; the hermaphrodite florets are tubulous, funnel-fhaped, and cut into five parts at the brim; they have each five hairy fhort ftamina, and an oblong naked germen; the germen of both turns to fingle oblong feeds. There are two fpecies, comprehending feveral varieties. Linnæus enumerates feven fpecies.

Feverfew grows naturally on banks in feveral parts of England, but is frequently cultivated in phyfic gardens to fupply the markets.

The leaves and flowers of this plant, the *matricaria parthenium* of Linnæus, have always been allowed one of the firft places among the hyfteric and uterine plants, and hence it derives its name from *matrix*, *the womb*. It is prefcribed in powder from a fcruple to half a dram for the dofe; but the much better way is in a ftrong infufion made in the manner of tea. Taken in this eafy manner for a continuance of time, it will bring the menfes, though fubject to be interrupted and irregular, to their true period; and will remove a number of complaints, the natural confequence of fuch an irregularity.

It is alfo an agreeable, warm, aperient, carminative bitter. It ftrengthens the ftomach, and difperfes flatulences; and the expreffed juice is faid to kill worms. Some likewife commend it in diforders of the head, and in all nephritic complaints. Hoffman gives it great praifes, ufed as a febrifuge. There were formerly kept fimple water and fyrup of *feverfew* in the fhops; but at prefent they are wholly difufed, and the dried herb only kept ready for fomentations, and fometimes as an ingredient in clyfters. The virtues of *feverfew* are in fome degree fimilar to thofe of chamomile.

Many fpecies of this plant are cultivated in gardens for the beauty of their flowers. They are propagated by fowing them in March, on a bed of light earth: when they are come up, they fhould be tranfplanted out into nurfery-beds, at about eight inches afunder; and in the middle of May they fhould be removed into the flower-beds where they are to ftand. They flower in July and Auguft; but they fhould not be permitted to feed, which always weakens, and often deftroys the roots; fo that the ftalks fhould be cut down to the ground when the flower decays.

FEVERFEW, *baftard*, *parthenium*, in *Botany*, a genus of the *monœcia pentandria* clafs. Its characters are thefe: it hath a flower compofed of hermaphrodite florets and female half-florets, which are included in a common five-leaved fpreading empalement. The hermaphrodite flowers which form the difk have one tubulous petal cut into five parts at the brim; they have five hair-like ftamina, the length of the tube. The germen is fituated below the flower, and is fcarce vifible; fupporting a ſlender ſtyle, having two ſtigma: thefe flowers are barren. The female flowers which compofe the rays or borders are ſtretched out on one fide like a tongue; thefe have a large heart-fhaped compreſſed germen, with a ſlender ſtyle, crowned by two long ſpreading ſtigmata. Theſe flowers are ſucceeded by one heart-fhaped compreſſed ſeed. There are two ſpecies. Miller.

The firſt ſort grows wild in great plenty in the iſland of Jamaica, and in ſome other of the Engliſh ſettlements in the Weſt Indies, where it is called *wild wormwood*, and is uſed by the inhabitants as a vulnerary herb. The ſecond ſort grows plentifully in ſeveral parts of the Spaniſh Weſt Indies, from whence the ſeeds have been brought to Europe. Theſe plants make no great appearance, ſo are ſeldom cultivated but for the ſake of variety.

FEUILLANS, an order of religious clothed in white and going bare-foot, who live under the ſtrict obſervance of the rule of St. Bernard.

The name was occaſioned by a reform of the order of Bernardins, firſt made in the abbey of *Feuillans*, a village in France, five leagues diſtant from Thouloufe, by the ſieur Barriere, who eſtabliſhed it about the year 1580. It was approved of by pope Sixtus V. and the popes Clement VIII. and Paul V. granted it its particular ſuperiors. King Henry II. founded a convent of *Feuillans* in the Fauxbourgh St. Honore at Paris in 1587.

There are alſo convents of nuns who follow the ſame reform, called Feuillantes; the firſt of which was eſtabliſhed near Thouloufe in 1590.

FEUILLE *de Scie*, in *Heraldry*, expreſſes that an ordinary, as a feſſe, pale, or the like, is indented only on one ſide; becauſe it then looks like the leaf of a ſaw, as the French phraſe imports.

FEVILLEA, in *Botany*, the name of a genus of plants of the *dioecia pentandria* claſs, called by Plumier *chondrifolia*; the characters of which are theſe: it produces male and female flowers diſtinct on the ſame plant; in the male flower the perianthium is campanulated; it is compoſed of one leaf, and is round at the bottom, but expanded at the mouth, where it is divided into five ſegments; the flower conſiſts of one leaf, and is of the rotated kind; it is highly divided into five ſegments at the edge; theſe are convex and rounded, and the umbilicus is covered with a double ſtar; the ſtamina are five filaments; in the female flowers the cup is the ſame as in the male; the flower itſelf is alſo the ſame, but that the ſtar which cloſes the baſe, is compoſed of five cloſed leaves. The fruit is a very large fleſhy berry with a hard bark, and is of an oval obtuſe figure, and ſurrounded with the calyx. The ſeeds are flatted, and of an orbicular form. There are two ſpecies.

FEWEL. See FUEL.

FEWMET. See FUMET.

FIANTS, or FYANTS, the dung of a badger, fox, and other vermin.

FIARSING, in *Ichthyology*, a name given by the Swedes and Danes to the fiſh generally called the *draco marinus* and *araneus marinus*, the ſea-dragon, and the ſea-ſpider. It is a ſpecies of the trachinus, according to Artedi, and is diſtinguiſhed from the others by its lower jaw being longer than the upper, and without beards.

FIAT, in *Law*, is uſed for a ſhort order or warrant of ſome judge for making out and allowing certain proceſſes. Thus, if a certiorari be taken out in vacation, and teſted of the precedent term, the *fiat* for it muſt be ſigned by a judge of the court, ſome time before the eſſoin day of the ſubſequent term, otherwiſe it will be irregular. There is no need for the judge to ſign the certiorari itſelf, but only where it is required by ſtatute.

FIAT *juſtitia*, is an order granted on a petition to the king for his warrant to bring a writ of error in parliament, in which caſe he writes on the top of the petition *fiat juſtitia*, and then the writ of error is made out, &c.

FIATOLA, in *Ichthyology*, a name given by the Italian fiſhermen to the STROMATEUS.

FIBER, in *Zoology*, or *fiber caſtor* of Linnæus, *beaver*, has ſtrong cutting teeth, ſhort ears hid in the fur, blunt noſe, hair of a deep chefnut brown, tail broad, almoſt oval, compreſſed horizontally, and covered with ſcales; the foreſeet are ſmall, and the hind-feet large: the length of the animal, from noſe to tail, is about three feet; the tail is eleven inches long, and three broad. See BEAVER, and *Tab.* II. *Quad. fig.* 13.

FIBRA *aurea*. See EAR.

FIBRARIÆ, in *Natural Hiſtory*, the name of a claſs of foſſile bodies, the greateſt part of which have been very improperly called by the writers of foſſils, fibrous talcs; they being of a very different ſubſtance and ſtructure of parts from the talcs, and having none of their diſtinguiſhing characters.

The word is derived from the Latin *fibra*, *a fibre or filament*, theſe bodies being all compoſed of arrangements of parallel filaments or fibres. See *Tab. of Foſſils, Claſs* I. The *fibrariæ* in general are foſſils compoſed of parallel filaments, uſually remaining ſo diſtinct as to preſerve in the whole maſſes a thread-like texture, but ſometimes uniting ſo as to form plates or flakes reſembling thoſe of the talcs in external figure. They are bright, and in ſome degree tranſparent, not giving fire with ſteel, nor fermenting with, or ſoluble in acid menſtrua. Hill's Hiſt. of Foſſ. p. 88.

Of this claſs of bodies, there are two diſtinct orders, and under theſe four genera. To this claſs belong the amianthus, aſbeſtos, lachnides, and trichites.

FIBRE, in *Anatomy*, a ſimple part of the animal body, called alſo *filament*; and when very ſmall, *fibrilla* or *capillament*.

A *fibre* is a long, ſlender, white thread; which being variouſly interwove or wound up, forms the various ſolid parts of an animal body; ſo that the fibres are the ſtamen or matter of the animal.

Anatomiſts uſually diſtinguiſh four kinds of *fibres*, viz. *carneous* or *fleſhy*, *nervous*, *tendinous*, and *oſſeous* or *bony*; of one or other of which all the other parts conſiſt. See FLESH, NERVE, TENDON, BONE, MUSCLE, and SENSATION.

Fibres, again, are divided with reſpect to their ſituation into *erect* or *long-itudinal*, which proceed in right lines; *tranſverſe*, which cut or go acroſs the former at right angles; and *oblique*, which interſect or croſs them at unequal angles.

Some anatomiſts reduce the animal *fibres* to two ſpecies, viz. *motorious* or *motives*, and *nervous* or *ſenſitives*.

FIBRES, *nervous*, are the minute threads whereof the nerves are compoſed. They ariſe from the medulla of the brain, as that does from the cortex; and that again from the

the laſt fineſt ramifications of the carotid and vertebral arteries; ſo that, it is probable, theſe nerves are, in reality, only continuations of theſe arteries.

From every point of the cortex there ariſes a fine medullary *fibrilla*: theſe, uniting in their progreſs, form the medulla of the cerebrum, cerebellum, and oblongata; and *fibrillæ* ariſing from each point of theſe again, form the ſpinal marrow.

From the medullary ſubſtance of all theſe parts ariſe nerves, which are combinations, or aſſemblages, of a number of theſe minute medullary *fibræ* incloſed, after they are got out of the cranium, in a common membrane, or coat, from the pia mater; and it is probable, that, to each nerve, there concur *fibræ* from all three; as, alſo, that theſe *fibræ* are ſo many fine hollow tubuli, or canals, for the conveyance of a fine juice, or ſpirit, from the brain, throughout the body. See NERVE.

FIBRES, *muſcular*, are thoſe whereof the muſcles, or fleſhy parts of the body, are compoſed. Every muſcle is diviſible into other leſs ones; and theſe into others, ſtill leſs beyond all imagination. The laſt and ſmalleſt are the muſcular *fibres*; concerning which it is queſtioned, whether or no they be vaſcular.

Mr. Lewenhoeck ſays, that he could plainly diſtinguiſh the fibrils, of which each muſcular *fibre* is compoſed, to be vaſcular; for, if he cut across their length, the light appeared through the mouths of the veſſels; but if he cut them obliquely, no light was to be ſeen; and he alſo found that each fibril is inveſted with a minute membrane, which is only a congeries of blood-veſſels; conveying juices and nutrition to it, though their ſmallneſs renders them inviſible; and that the *fibres* are through their whole length encompaſſed with circular wrinkles. Phil. Tranſ. N° 367. Lewen. Op. tom. i. p. 49. tom. ii. p. 61, &c. ed. 1722.

That the muſcular *fibres* are vaſcular has alſo been ſuppoſed by Malpighius Borelli, Gorter, and Hooke, to whom they appeared like ſtrings of pearls; and alſo by Dr. A. Stuart, in his treatiſe De Motu Muſculorum, where from ſuch a ſtructure, and by the influx of the nervous fluid, he endeavours to account for the elaſtic force, the contraction, diſtenſion, and all the actions of the MUSCLES.

Now there are nerves propagated to every muſcule, and diſtributed through the body thereof; ſo that there is no aſſignable point wherein there is not ſomewhat of a nerve. Add, that all the nerves here diſappear; and that in other parts of the body, the extremities of the nerves are expanded into membranes. It is therefore probable, that the muſcular *fibres* are only continuations of the nervous ones.

The animal *fibres* have different properties; ſome are ſoft, flexible, and a little elaſtic; and theſe are either hollow, like ſmall pipes; or ſpongious, and full of little cells, as the nervous and fleſhy *fibres* above mentioned.

Others are more ſolid, flexible, and endowed with a ſtrong elaſticity, or ſpring; as the membranous and cartilaginous *fibres*.

A third ſort are hard and inflexible; as the *fibres* of the bones.

Of all theſe, ſome again are very ſenſible, and others wholly deſtitute of ſenſe; ſome ſo very ſmall, as not to be eaſily perceived; and others on the contrary, ſo big, as to be plainly ſeen; and moſt of them, when examined with a microſcope, appear to be compoſed of ſtill ſmaller *fibrillæ*.

Theſe *fibres* firſt conſtitute the ſubſtance of the bones, cartilages, ligaments, membranes, nerves, veins, arteries, and muſcles. And again, by the various texture, and different combination, of ſome or all of theſe parts, the more compound organs are framed; ſuch as the lungs, ſtomach, liver, legs, and arms; the ſum of all which make up the body.

The great property of *fibres* is elaſticity, or a power of contraction, after the diſtracting force is removed; upon the knowledge of which that of the animal mechaniſm greatly depends.

To underſtand this, it may be obſerved, that any membrane or veſſel may be divided into very ſmall *fibres*, or threads; and that theſe threads may be drawn out into a very conſiderable length, without breaking; and that when ſuch external force is removed, they will again reſtore themſelves to their proper dimenſions. It is farther alſo manifeſt, that this property is preſerved to them by a convenient moiſture; becauſe if one of theſe threads be dried, it immediately loſes it; ſo that upon the application of any force to ſtretch it, it will break; its lying ſoaked in liquor too much will, on the other hand, render it flaccid, and deſtroy all its power of reſtitution, when diſtended.

Now, ſome hints of that configuration of parts, upon which this property depends, Dr. Quincy maintains, may be had from the contrivance and properties of a ſyringe; with the reaſon why it is ſo difficult to draw back the embolus, when the pipe is ſtopped; and the neceſſity of any liquor's following it, wherein the pipe is immerſed. All that is neceſſary hereto, is, that the embolus be ſo exactly adapted to the inner ſurface of the barrel, as to prevent any air paſſing between them, when it is drawn up: it matters not what figure the barrel is of, ſo that the embolus be well fitted to it. A caſe of ſyringes therefore might be contrived, wherein every barrel may alſo ſerve as an embolus to the exterior one, which immediately includes it.

In this manner it is not difficult to imagine a continued ſeries of particles ſo put together, that they may be moved and drawn upon one another, without ſuffering the air immediately to enter into the interſtices made by their diſtraction; whereupon as ſoon as that force, which drew them, is removed, they will, for the very ſame reaſon as the embolus of a ſyringe, ruſh up again into their former contacts.

As ſuppoſe A B (*Tab. Nat. Hiſt. fig.* 6.) two particles touching one another in *e f*, and C D two others, covering the oppoſite ſides of their contacts. It is alſo to be ſuppoſed, that on the other ſides they are covered with other particles in the ſame manner, as by C D, ſo that the places of their contacts are on all ſides covered from the air, or the inſinuation of any fluid body.

If now A B by an external force, greater than that of their cohæſion, be drawn from each other, as far as G I and H K (*fig.* 7.); as ſoon as that force is removed, they will again run into their former contacts in *e f* (*fig.* 6.); that is, if they be not ſo far ſeparated as to bring their tranſverſe ſurfaces to coincide with C and D; for then the air, or circumambient fluid, will interpoſe, and prevent their re-union; ſo that by this contrivance, ſo much of A and B as is incloſed by other ſurrounding particles, is as the embolus of a ſyringe, and the particles ſurrounding them as its barrel. And therefore when A and B are diſtracted from their contacts in *e f*, it will be with ſome difficulty; and when the diſtracting force is taken away, they will again run into their former contacts; juſt as the embolus of a ſyringe, and for the ſame reaſon.

It is not rigidly contended, that this muſt exactly be the contexture of a *fibre*, but only ſomething like this; whereby the interſtices of the interior orders are covered by the exterior in ſuch a manner, that when the thread is diſtended, that is, when its conſtituent parts are drawn from their tranſverſe contacts, neither the air, nor any other external fluid, can get between them, ſo as to hinder their re-union as ſoon as ſuch force is withdrawn; that is, if their diſtraction, as was before ſaid, be not ſo far as to bring their tranſverſe ſurfaces to a coincidence with one another; for then the circumambient fluid will interpoſe, that is, the thread will be broke.

But beſides this peculiar arrangment of a determinate ſet of particles to compoſe the main ſubſtance of an animal *fibre*, endowed with the properties above mentioned; it ſeems not at all unreaſonable to conjecture, that into their compoſition there alſo enters a common capſula, or covering, which aſſiſts in the wrapping up, and holding together, thoſe faſciculi, or aſſemblages of particles already deſcribed, not much unlike the perioſteum of the bones; the contexture of which covering, reſembling that of a net, cannot any ways hinder either the tranſverſe, or longitudinal diſtractions of the other parts.

Supposing this, then, the contexture of a *fibre*, it will be neceſſary to conſider what farther requiſites are needful to put them into that ſtate which they are in, in a living body; to ſhew how they are maintained in continual motion, and what are the conſequences of it.

And, 1. It is neceſſary to take notice, that all the *fibres* in a living body are in a ſtate of diſtention; that is, they are drawn out into a greater length than they would be in, if ſeparated from the part, and taken out of the body; which is demonſtrable upon any ſolitio continui, as in the tranſverſe diviſion of a nerve, or artery; for immediately the divided parts run up, and leave a great diſtance between them; and the fluids contained between them, upon ſuch contraction, are ſqueezed out. This alſo ſhews, that their natural diſtractions are owing to ſome fluids being propelled into the veſſels which they compoſe, with a force greater than their endeavours of reſtitution, ſo far as to obtain a cloſe contact of all their tranſverſe ſurfaces, but yet leſs than that which is neceſſary to diſtract them, ſo as to bring them into a coincidence; for then the veſſels would break.

2. This ſtate of diſtraction muſt neceſſarily leave vacuola between all the tranſverſe ſurfaces; as between G I and H K (*in fig.* 7.) which may be repreſented by the ſe-

veral series of particles *fig.* 8. *b*, which vacuola will continue as long as the longitudinal surfaces of the component parts continue to close to one another, as to prevent the insinuation of any foreign matter, how subtile soever, between them.

For the same reason, therefore, as when the embolus of a syringe is drawn, and the pipe is stopped, there must be continually a *nisus repitendi*, or an endeavour of contraction. There is also this further necessity of their being continued in a state of distraction; because if they were closely to touch one another in all parts, they could not be put into, and continue in, those undulatory motions, which they are always in, in a living body, without being altered in their figures and contextures.

3. It being manifest, that all animal *fibres* are continued by the perpetual successive impulse of the fluids, in such undulatory motions; besides this necessity of their distraction, they must also necessarily be continually anointed with some convenient fluid; because otherwise their continual attritions against one another would wear them out, as well as render it difficult to move them; the fluid also, for this purpose, must be very soft and subtile, because otherwise it could not insinuate itself into all the interstices of the *fibres*, whereon to far separating their parts, as is inconsistent with that contexture and mechanism here laid down.

Upon this view there arises a very natural explication of several terms, much used by mechanical writers; such as *distention*, *contraction*, *vibration*, *undulation*, *tone* or *tension*, *crispation*, *relaxation*, *corrugation*, and *capacity* of the solids; all which are but different ways of expressing the various modifications and dispositions of those machinulæ, whereof all the *fibres* are composed.

Thus much being granted of the contexture of a *fibre*, and the requisites for its office, it is to be considered, how it comes first to be set in motion, and by what mechanism that motion is afterwards carried on. Suppose then the *fibre fig.* 8. *i* in such a state of distraction, as before mentioned; it is certain by *exp.* 2. that in all parts there is a *nisus repitendi*; where, then, any external impulse is made against it from R to S, successively, thrusting it from P towards Q, it is certain that against it, for instance, the thread will be more distracted than in any other part; and thus there will be a greater endeavour of restitution; and therefore the impulse passing on towards S, all the constituent machinulæ, 1, 2, 3, 4, will successively move one after another.

To make this matter still more plain, let a portion of an artery be represented by *fig.* 9. through which the blood is continually propelled in a direction parallel to its axis; nothing is more certain than that it it were not for the resistance of the sides of the artery at E, F, the blood setting out at A, B, would go on by the pricked lines C, D; and therefore it cannot but strike against the sides of the artery at E, F, and distract them more than any where else; whereby their endeavours of restitution will be there the greatest; and therefore, when the impulse of the blood has raised them to a certain measure, wherein their endeavours of restitution will exceed the impulse which raised or distracted them, their contractile powers will draw them again into the same dimensions; and consequently the blood will be thrust forward into the next section of the artery, and so on successively from one to another, through the whole course of its circulation: the contraction of one section of an artery being the true cause of the blood's impulse against, and raising the next. See MUSCLE and *Motion* MOTION.

FIBRE is also applied, in *Physics*, to those long, fine parts, or threads, whereof other natural bodies are composed, and which present their being friable or brittle.

Trees, plants, and fruits, have their *fibres*, or capillaments; which are modifications of their woody substance, penetrating and terminating in the parenchyma, or pith.

In the common sense, *fibre* is chiefly applied to the slender capillary roots of plants.

Keplervera gives *fibres* to the flame and explains several of their motions from the situation of their *fibres*.

FIBRILLA, a little FIBRE, or capillament.

FIBROUS *roots*, those which consist wholly of small fibres, such as the roots of the meadow-grass pinks, and several other flowers. When a *fibrous* root penetrates straight into the ground, it is called *perpendicular*; when it creeps under the surface *horizontal*; when somewhat thick, it is called *tuber*; when very thin, *capillary*; when it runs all the way undivided, *simple*; when divided, or when it sends off smaller roots, *branched*; when its surface is covered with extremely short and fine fibres, *hairy*. See ROOT.

FIBULA, in *Anatomy*, one of the bones of the leg, called also *peroneus*, *fora*, and *fusile minus*. See *Tab. Anat. (Osteol.) fig.* 3. *n.* 24. 24. *fig.* 7. *n.* 27. 27.

The *fibula* is the outer and slenderer of the two bones of the leg; and yet, notwithstanding its being more exposed, and its being much weaker, than the inner bone, or tibia, it is not so often broken, as being more pliant and flexible: whence the tibia often breaks, leaving the *fibula* entire.

The *fibula* is joined or articulated with the tibia, at both ends. It is divided into three parts. The upper extremity of this bone is a kind of tuberosity or head, obliquely flatted by a small cartilaginous plane, by which it is articulated with the cartilaginous surface, of the lower part of the external condyle of the tibia. It terminates backward by a kind of short blunt point called *styloid*. The lower extremity is broader, flatter, and more oblong than the upper; it is partly a continuation of the body of the bones, and partly an epiphysis in children; the marks of which are quite lost in a more advanced age. It has in a manner three sides, one round like a tuberosity, one flat, and the third narrow; when it is placed in the lateral cavity of the bone of the tibia, it makes the outer ankle opposite to the inner ankle.

In its natural situation, it reaches much lower down than the bone of the tibia, and runs in a point turned a little backward. The flat side is cartilaginous, and turned toward the cartilaginous side of the inner ankle, with which, and with the inferior side of the bone of the tibia, it completely forms the cavity by which the leg is articulated with the foot. The narrow side is turned backward, and near its lower part is a small, *oblong*, unequal fossula, formerly believed to be for the passage of a tendon, in which a small sesamoidal gland is lodged. The point by which the bone of the *fibula* ends, has a small smooth surface immediately below the narrow side, for the insertion of an annular ligament.

The body of this bone is long and small, more or less contorted, and irregularly triangular. Near the two extremities it contracts into a kind of neck, and a little below the middle it is often bent inward; but this curvature seems chiefly owing to the method of dressing children, for we sometimes meet with the bone very straight. It is distinguished in an irregular manner into three sides, and three angles, principally towards its lower part. The outside is the most considerable; the upper part of it is more or less hollowed; afterwards it grows round, and altering its direction, becomes almost posterior in the lower half. The posterior side is more or less convex toward the upper part, thence it grows flat, and forming in the same manner as the former, it becomes nearly internal toward the lower part. The inner side has likewise a turn near its middle, and becomes anterior from thence downward; and this turn is marked by an oblique line, which runs down on this side, from behind, forwards, and divides it into two. These sides serve partly for muscles to be upon, and partly for their insertions. The internal angle of the *fibula* answers to the external posterior angle of the tibia, and both serve for the insertion of the interosseous ligament of the leg; the other two angles are more or less acute, especially the anterior, which is sometimes like a kind of crista, and terminates below in a small triangular surface.

The internal structure of the *fibula*, though a very small bone, is like that of the other long bones; it is articulated by its upper extremity, with the inferior surface of the external condyle of the tibia; this articulation is an arthrodia, with a very small degree of motion. The inferior extremity is articulated by its cartilaginous side, partly with the lateral depression in the bone of the tibia and partly with the fifth bone of the foot, completing the gingiglimus between the leg and that bone. Winslow's Anatomy, p. 95.

FIBULA, *cartilages of the*. The *fibula* has two cartilages, one lying on the upper extremity of that bone, for its articulation with the small cartilaginous surface in the head of the tibia; the other cartilage covers the inside of the inferior extremity, or the outer ankle, near the point of which, posteriorly, there is a superficial cartilaginous incrustation for the passage of the tendons of the musculi peronæi. The cartilage at the upper extremity seems thicker than at the lower. Winslow's Anatomy, p. 128.

FIBULA, *ligaments of the*. This bone is joined to the tibia by nine ligaments, four at each end, and one in the middle, called the interosseous ligament. The four at the upper extremity are short, very strong, more or less oblique and compound; two of them are anterior and two posterior, and they lie on each other; the superior ligament surrounding the articulation more closely than the inferior which have a small void space, and are weaker than the former; they are all fastened to the capsular ligament, which runs in between them and the articulation, and they are inserted round the edges of the cartilaginous surfaces in each bone.

The ligaments of the lower extremity of the *fibula*, which runs below the tibia, and forms the outer ankle, are much ſtronger, thicker, more complex, broader, longer, and more oblique, than thoſe of the ſuperior extremity; and are like thoſe diſperſed, two before and two behind. They are fixed to the anterior and poſterior edge of the lateral depreſſion at the inferior extremity of the tibia, and from thence they run down on the lower end of the *fibula*. The two inferior ligaments are longeſt and they are fixed anteriorly and poſteriorly at the lower end of the outer ankle; the two ſuperior are fixed more cloſely, and nearer each other, but there is ſtill a ſmall ſpace between them, which is filled with fat. As the two bones touch each other only by the upper part of the cartilaginous ſurface of the outer ankle, and the ſmall cartilaginous border in the lower edge of the depreſſion of the tibia, the middle ſpace between them is filled by a capular ligament, which lines each ſide of the bones, and is continued down to the true articulation of the external ankle, with the inferior edge of the baſis of the tibia.

The middle or interoſſeous ligament of the two bones of the leg is called, becauſe it fills up all the ſpace left between them, being ſtretched from one to the other, is fixed along the poſterior external angle of the tibia, and the neighbouring angle of the *fibula*. It is made up chiefly of two planes of very oblique ligamentary fibres, which croſs each other, and at different intervals ſeem to be multiplied. It is perforated both above and below, and ſometimes in ſeveral places beſide, for the paſſage of the blood-veſſels and nerves. It is not a ligament intended for the tying of theſe two bones together, but is rather a ligamentary ſeptum for the inſertion of muſcles, ſupplying in this reſpect the place of a bone, and ſeeming indeed to be partly a continuation of the periofteum of the tibia and *fibula*. At the lower part of each ankle, there are commonly three ſtrong ligaments for the connection of the bones of the tarſus with thoſe of the leg; one of theſe runs downward, one backward, and one forward. Wenſlow's Anat. p. 130.

FIBULA, *luxation of the*. Sometimes the *fibula* is ſeparated by external violence from the thigh bone, and is then diſtorted either upwards or downwards: this generally happens, when the foot has been bended outwards. Whenever this happens the bone is to be firſt reſtored to its natural place, and then properly bound up, and left to the aſſiſtance of nature and reſt, till it be grown firm again to the tibia and leg. The patient in this and the like caſes muſt be always ſtrictly cautioned not to uſe or bear any ſtreſs upon the diſordered leg too ſoon; the conſequence of which may be worſe than the firſt misfortune. Heiſter's Surg. p. 172.

FIBULA, in *Natural Hiſtory*, a name given to a claſs of the *echinodermata*, which have their mouth in the middle of the baſe, and the aperture of the anus on one edge. Theſe are found principally among the ſoſſile kinds, and ſeem to have had their ſhells of the articulated kind, or compoſed of ſmall plates joined tranſverſely to one another. Of this claſs there are two genera, the CONDULI and DISCOIDEA.

FIBULA, in *Surgery*, an inſtrument in uſe among the ancients, for the cloſing of gaping wounds.

Celſus ſpeaks of the *fibula*, as to be uſed when the wound was ſo patent as not eaſily to admit of being ſewed. Op. lib. vii. cap. 25. apud fin.

Authors are ſomewhat at a loſs as to the form of the ancient *fibula*. Guido ſays they were iron circles, or ſemicircles, bent backwards both ways; the hooks whereof, being faſtened on both ſides to the wound, anſwered exactly to each other; but as this muſt have been an inſupportable pain to the patient, this deſcription is generally ſet aſide.

Fallopius, Sanctorius, and others, take the word *fibula* to have ſignified, in reality, no more than the ſewing up of the wound with a needle and thread, as uſed at this day.

FIBULÆUS, in *Anatomy*, a muſcle of the leg called alſo *peroeus-peronæus primus*.

FICARIA, in *Botany*, a name uſed by ſome authors for the ſmall celandine, pilewort, or figwort.

FICEDULA *cannabina*, in *Ornithology*, a name by which ſome authors have called the CANNAVARGLA, or leſſer SPARROW.

FICHANT, *Figure*, a French term, uſed in *Fortification*; that, a flank *fichant*, or a line of defence *fichant*, is a place, whence the flank made do not only take the oppoſite face to be defended, but alſo enter within it.

The word is formed of *ficher*, *to fix a thing in*.

FICHE, in *Heraldry*. See FITCHEE.

FICOIDES, a name uſed by different authors in botany for different plants; many underſtanding by it the *aizoum*, or Indian fig, as it is vulgarly called. See *Prickly* PEAR. And ſome, as Herman and others, making it the name of the muſa or PLANTAIN-*tree*.

FICTION. See FABLE.

FICTION *of a perſon in Rhetoric*. See PROSOPOPEIA.

FICTION *of law*, *Fictio Juris*. *Fictions* are allowed of in law, in ſeveral caſes, but muſt be framed according to the rules of law, nor what is imaginable in the conceptions of man; and there ought to be equity and poſſibility in every legal *fiction*. There are many of theſe *fictions* in the civil law; and by ſome civilians it is ſaid to be an aſſumption of law upon an untruth for a truth, in ſomething poſſible to be done, but not done. Godolphin and Bacon. The feiſin of the conuſee in a fine, is but a *fiction* in our law; it being an invented form of conveyance only. 1 Lilly's Abr. 616. And a common recovery is *fictio juris*, a formal act or deviſe by conſent, where a man is ſuppoſed to vouch off an eſtate tail, remainder, &c. 10 Rep. 42. The proceedings in ejectments are alſo grounded on a *fiction of law*.

FICUS, in *Botany*. See FIG-*tree*.

FICUS, in *Conchology*, a name given by authors to a peculiar ſpecies of ſea-ſhell. It is of the genus of the *ſolidum*, and has a remarkably depreſſed cluſter.

FICUS, in *Surgery*, a kind of fleſhy excreſcence, growing ſometimes on the eye, or eyebrows, or chin; but more uſually on the anus, or at the ſphincter ani.

It is alſo called *ſycoſis*, *ſycoma*, *ſycotes*, *ſycoſis tumor*, and *marciſca*.

FIDD, an iron pin uſed at ſea to ſplice or faſten ropes together; it is made tapering and ſharp at one end.

There are alſo *fidds* of wood, which are much larger than the iron ones.

The pin alſo in the heel of the topmaſt, which bears it upon the creſt-tree, is called a *fidd*.

FIDD-*hammer*, is uſed for a hammer, the handle of which is a *fidd*, or tapering into that form.

FIDDLE. See VIOLIN.

FIDDLE-*dock*, in *Botany*. See DOCK.

FIDDLE-*weed*. See CYTHNEZYLON.

FIDE-*inſtare aſſidui*. See ASSIDUUS.

FIDE-*juſſor*, in the *Civil Law*, is a ſurety, or one that obliges himſelf in the ſame contract with a principal, for the greater ſecurity of the creditor, or ſtipulator.

FIDEI-*Commiſſum*, in the *Roman Law*, the appointing of an heir, or bequeathing a legacy to a perſon, on this condition, that he ſurrender the inheritance or legacy to another perſon, for whom the ſame is originally meant; or it is an inheritance left in truſt with any one, for the uſe of another.

Fidei-commiſſa were much uſed among the Romans. In the French law the thing is become odious; as being, ordinarily, no other than an expedient in favour of perſons to whom the laws forbid any thing to be given. In order to this, ſome truſty friend is choſen to be made legal heir, under a tacit agreement, to deliver the inheritance to the perſon incapacitated by law. But of late times the ſame expedient has come in uſe with regard to perſons capable of inheriting; to whom the teſtator, for particular reaſons, does not care to leave the inheritance directly.

As it happened, that the *fidei-commiſſaries* did not always faithfully teſtore what was truſted to them, Auguſtus took proper meaſures to oblige them thereto: to this end a prætor was erected, whoſe buſineſs was reſtrained to the ſingle matter of *fidei-commiſſum*.

As a teſtament was void without the inſtitution of an heir; and it frequently happening, that the *fidei-commiſſary* refuſed to accept the truſt, upon which the teſtament fell to the ground; to engage ſomebody to accept it from a conſideration of advantage, the Pegaſian ſenatus conſultum decreed, that the *fidei-commiſſary* ſhould be at liberty to retain a fourth of the *fidei-commiſſum*.

FIDELES, in *Church Hiſtory*. See BELIEVERS.

FIDICINALES, in *Anatomy*, a name given to ſeveral muſcles of the fingers, called alſo LUMBRICALES.

FIDICULÆ, in *Antiquity*, is often uſed to ſignify the ſame with FIDULEUS, a kind of puniſhment uſed among the ancients.

FIDICULÆ, in a more proper ſenſe, denotes the cords wherewith the criminals limbs were ſtrained on the FIDULEUS.

FIEF, the ſame with *feud* or FEE.

FIELD, in *Agriculture*, a piece of land incloſed, and fit for tillage to bear corn, or hay, &c.

For the method of finding the contents of a *field*, ſee AREA, CHAIN, and SURVEYING.

FIELD-*ale*, or FILCTALE, in our *Ancient Cuſtoms*, a kind of drinking in the field, by bailiffs of hundreds; for which they gathered money of the inhabitants of the hundred to which they belonged. But this cuſtom has been long ſince prohibited.

FIELD, *Campus*, in *Antiquity*, is frequently uſed for a public place, or ſquare in a city, &c.

Such were the *Field* of Mars, *Campus Martius*; and *Field*

of

of Flora, *Campus Floræ*, in Rome; and the *Field* of May, *Campus Maii*, among our ancestors, &c.

FIELD *of Mars* was denominated from a temple of that deity, built therein; it was the scene, or place, of the assemblies called *comitia*. Tarquin the Proud at length appropriated it to his own use; but after the expulsion of the kings, the consuls Brutus and Collatinus restored it to the public use again, for assemblies and elections.

Originally it was no more than a meadow on the banks of the Tiber, where horses grazed, and the Roman youth were exercised to war. But it was afterwards erected into a magnificent square, adorned with statues, &c. See CAMPUS *Martius*.

FIELD *of Flora*, was the place where the laws, edicts, and constitutions, were published.

FIELD *of May*, see CAMPUS *Maii*.

FIELD *basil*, in *Botany*. See CLINOPODIUM.

FIELD *basil, American*. See MONARDA.

FIELD *basil, Syrian*. See BASIL.

FIELD, *close*, was anciently a place enclosed, or railed in with a barrier, for justs and tournaments to be performed in.

FIELD, *Elysian*. See ELYSIAN.

FIELD *fort*. See *Field* FORT.

FIELD *works*, in *Fortification*, are those thrown up by an army, in the besieging of a fortress; or else by the besieged, in defence of that place. Such are the fortifications of camps, highways, &c.

FIELD, in *Heraldry*, is the furface, or face of the fhield, or efcutcheon: thus called, as containing the atchievements anciently acquired in the *field* of battle.

The *field* is the ground whereon the colours, bearings, metals, furs, charges, &c. are repreſented. In blazoning a coat, we always begin with the *field*: he bears fable, &c.

Among the more modern heralds, *field* is leſs frequently uſed than fhield, or efcutcheon.

FIELD *colours*, in the *Military Art*, are ſmall flags about a foot and a half ſquare, which are carried along with the quarter-maſter-general for marking out the ground for the ſeveral ſquadrons and battalions of an army. They are placed on the right and left of the parade of a regiment when in the field; they are of the ſame colour with the facing of the regiment, and have the number of the regiment upon them. See FLAG.

FIELD-*marſhal* is the denomination of a modern military rank in England, but ſuperior to all others; having the chief command of the whole army.

FIELD *officers*. See OFFICERS.

FIELD-*fare*, in *Ornithology*, the Engliſh name of a bird of the thruſh kind, called by authors *turdus pilaris*. It is larger than the common thruſh, and is of a bluiſh grey colour on the neck; the head is ſpotted with black, and the ſhoulders and back are of a yelloviſh brown, variegated with black; the throat is variegated with black and yellow, the lower part of the belly is white, and but a little ſpotted; and on each ſide of the neck, and near each eye, it has a large black ſpot; thoſe on the neck are on its lower part near the inſertions of the wings; its wing-feathers are variegated with black, white, and a yelloviſh brown, and the tail is of a bluiſh black, with ſome variegations of black and white; the legs are black, and the talons very ſtrong. Theſe birds generally weigh about four ounces; their length is ten inches, and their breadth ſeventeen.

It is a bird of paſſage, and viſits us in England toward the end of autumn in vaſt flocks, and leaves us in ſpring; it is not certainly known where they breed. They feed on berries, particularly thoſe of the holly, and are a well taſted bird.

This bird is eaſily taken with water bird-lime in the following manner: take out a gun, and kill two or three *field-fares* with it; by that time the gun has been diſcharged two or three times, the reſt of theſe birds will be ſo fly, that there will be no coming near them; then tie one or two of thoſe that were ſhot to the upper branches of a buſhy tree, in ſuch manner, that they may ſeem alive and ſitting there. Then prepare two or three hundred twigs, covering them well with the water bird-lime, made warm for that purpoſe; take a good birchen bough, and in that place all the twigs; tie this faſt to the tree, juſt underneath where the other *field-fares* are tied, and let this be in a place where they come in a morning to feed, for they always uſe one haunt for feeding ſo long as there is any food left there. By this means the *field-fares* will ſettle in whole flocks, near thoſe which they ſee tied to the buſh; and two or three dozen may be in this manner taken at a time. See BIRD and LIME.

FIELD *of a painting*, &c. is more uſually called the GROUND thereof.

FIELD-*pieces* are ſmall cannon, uſually carried along with an army in the *field*: ſuch as one, one and a half, two, three, ſix, nine, and twelve pounders; which being light and ſmall, are eaſily carried.

The ſmall pieces differ in length and weight: the dimenſions of the others are exhibited in the following table.

Braſs field-pieces.

Calibre.	Length. Feet.	Inch.	Weight. C.	Q.	lb.
12	5	0	8	3	8
6	4	6	4	3	10
3	3	6	2	2	10

See CARRIAGE and GUN.

FIELD-*ſtaff*, is a ſtaff carried by the gunners, in which they ſcrew lighted matches, when they are on command; which is called arming the *field ſtaff*. See LINSTOCK.

FIELD *of vision*, in *Optics*, is that conical ſpace indefinitely extended before us, ſo as to include all objects that can be ſeen at one view, or without turning the eyes. The preciſe limits of this ſpace are not eaſily aſcertained. In looking at a ſmall diſtance, we have an imperfect glimpſe of objects through almoſt the extent of a hemiſphere, or at leaſt for above ſixty degrees each way from the optic axes; but towards the extremity of this ſpace, objects are very imperfectly ſeen; and the diameter of the *field* of diſtinct viſion does not ſubtend an angle of more than five degrees at moſt; ſo that the diameter of a viſible image on the retina is leſs than $\frac{1}{36}$ of an inch; but it is probably much leſs. See VISION.

FIELD-*book*, in *Surveying*, a book uſed for ſetting down angles, diſtances, and other things, remarkable in taking ſurveys.

The pages of the *field-book* may be conveniently divided into five columns. In the middle column the angles at the ſeveral ſtations taken by the theodolite are to be entered, with the diſtances from the ſtations. The diſtances taken by the off-ſet ſtaff, on either ſide of the ſtation line, are to be entered into the columns on either ſide of the middle column, according to their poſition with reſpect to that line. The names or characters of the objects, with proper remarks, may be entered in the columns on either ſide of theſe laſt mentioned.

FIELD, in *War*, the place where a battle was fought. The general remained maſter of the *field* of battle.

FIERI *facias*, in *Law*, a judicial writ, which lies at all times within the year and day, for him that hath recovered in an action of debt and damages: it is directed to the ſheriff, commanding him to levy the debt and damages on him againſt whom the recovery was had.

FIFE, in *Muſic*, a ſort of wind inſtrument, being a ſmall pipe.

FIFE-*major*. See MAJOR.

FIFE-*rails*, in a *Ship*, are thoſe that are place don baniſters on each ſide of the top of the poop, and ſo along with *hances* or rails. They reach down to the quarter-deck, and to the ſtair of the gangway.

FIFTEENTH, *Decimus quintus*, or *Quinzieme*, an ancient tribute, or impoſition of money, laid upon any city, borough, or other town, through the realm; not by the poll, or upon this or that man, but in general upon the whole city or town.

It is ſo called, becauſe it was ſuppoſed to amount to a *fifteenth* part of that which the city hath been valued at of old; or to a *fifteenth* part of every man's perſonal eſtate, according to a reaſonable valuation.

This was impoſed by parliament, and every town through the realm knew what a *fifteenth* for themſelves amounted to, becauſe it was always the ſame; whereas the ſubſidy, which was raiſed of every particular man's lands, or goods, muſt needs be uncertain.

The *fifteenth* ſeems to have been a rate anciently laid upon every town, according to the land or circuit belonging to it. Camden mentions many of theſe *fifteenths* in his Britan. viz. p. 171. *Hoth geldabat pro viginti hidis, quando ſcira geldabat*, &c. And p. 181. *Old Sarum pro quinquaginta hidis geldabat*, &c. Which rates are according to Doomſday. But in after-times the *fifteenth* came to be underſtood as impoſed only on goods and chattels, not on lands. It was firſt granted by parliament, 18 Edw. I. viz. *Computus quintæ decimæ regi, an. 18. per archiepiſcopos, epiſcopos, abbates, priores, comites, barones, & omnes alios de regno, de mobilibus bonis mobilibus conceſſus*. The city of London paid that year for the *fifteenth* 2860l. 13s. 8d. and the abbot of St. Edmund's 666l. 13s. 4d. which was by compoſition; and thereupon had all the temporal goods of their diſtrict diſcharged of the *fifteenth*.

In the 8th of Edw. III. it was reduced to a certainty, when, by virtue of the king's commission, new taxations were made of every township, borough, and city, in the kingdom, and recorded in the exchequer; which rate was, at the time, the *fifteenth* part of the value of every township, and the whole amounted to about 29,000*l.*

The way of collecting it was by two aldermen appointed in every county by the king, who appointed twelve more in every hundred to make a true valuation of every man's personal estate upon which the *fifteenth* part was levied.

FIFTH, in *Music*, one of the harmonical intervals, or concords.

The *fifth* is the third, in order, of the concords. The ratio of the chords that produce it, is 3 : 2.

It is called *fifth*, because it contains *five* terms, or sounds, between its extremes, and four degrees: so that in the natural scale of music it comes in the *fifth* place, or order, from the fundamental.

The ancients called this interval DIAPENTE.

The *imperfect*, or *defective fifth*, by the ancients called *semi-diapente*, is less than the *fifth* by a mean semitone.

FIG *tree*, *Ficus*, in *Botany*, a genus of the *polygamia frustranea* class. Its characters are these: it hath male and female flowers included within the skin of the fruit; so that they do not appear, unless the covering be opened: the male flowers are but few in number and are situated in the upper part of the fruit; the female flowers are numerous, and situated in the lower part. The male flowers sit each upon a separate foot-stalk, and have no petals, but three briftly stamina; the female flowers sit upon distinct foot-stalks; they have no petals but a germen, which afterward becomes a large seed, sitting in the emplacements. There are eleven species; some of which are cultivated in the gardens of England, but many more in those of France and Italy, where the fruit is in very high esteem, as it is also with the nicer palates here; though so much out of favour with the vulgar, that it stands safe on trees planted in places where every other species of fruit would be stripped by robbers.

One great discouragement to their more frequent propagation in England, is the unwillingness of the generality of our gardeners in their culture and management. To obviate which, it may not be amiss to say somewhat at large here, of the proper management of all the species of this tree.

The common method has been to propagate these trees by suckers from the roots of the old ones, but they are much more successfully raised from cuttings. These should be taken from the trees in autumn, and chosen from such branches as are compact, with their joints near each other; they should have a part of the former year's wood at their bottom, and the top of each should be left entire. They then should be planted, eight or nine inches deep, in a bed of loamy earth, warmly situated; the surface of the ground should be covered with old tanner's bark, three or four inches thick, and in severe frost their tops should be covered with straw, &c. which should be removed in the spring, but the tan should be suffered to remain. In the following autumn, they will be fit to remove. This is the proper season to transplant them; and the best soil is such as has a gravelly, chalky, or stony bottom, with a light surface; the tree will seem to flourish indeed more in a better soil, but in this poor one it will produce the finest and most splendid fruit. They should always be planted in a free open situation, not shaded by trees or buildings, and will never ripen their fruit well, unless against a good south, south-east, or south-west wall. They should be planted at twenty feet distance, and the height for the wall they stand against is about fourteen feet; the middle spaces between the trees may be planted with vines to fill up the vacant part of the wall till the *figs* are grown; and then these should be taken up. In the summer, as the branches shoot, they must be trained horizontally against the walls and no foresight shoots should be suffered to come, but the buds of such should be rubbed off as fast as they appear. At Michaelmas they should be always pruned and nailed up. The great care to be had in pruning the old trees, is always to have a supply of young branches for those only produce fruit. None of the shoots of the former autumn pruning must be shortened; for it is on the two year old wood, that the fruit is produced; the young branches must be always brought very close to the wall, and this will screen them from injuries by frosts, and much forward the early ripening of their fruit. The old branches should never be laid in too thick, which is a great fault among most gardeners; the distance ought to be at least a foot between branch and branch; and as the young ones grow strong, the old ones should be always cut away. In April, or the beginning of May, several of the leading shoots should be stopped, which makes them throw out side-branches. In autumn the trees may be loosened from the walls, and the branches may be laid down and tied to stakes, so as to keep them from the damp ground: and thus in very hard weather be covered with straw, pea-haulm, or the like; and that not to be removed till the weather is milder, and then not all at once, but only by a little at a time. In mild weather the covering should be removed; or else the *figs* will come out too early, and be damaged by the cold of April and May. In the spring, when the *figs* begin to push out, the trees may be fastened to the wall again. The higher the wood runs up the wall, usually so much the better suited to the fruit; and no trees succeed better in fruiting than those which are nailed up against chimnies, where, beside the height, they have some advantage from the heat.

Fig-trees are always planted as standards in warm countries; but in England they are generally planted against walls; however, since some of the varieties are found to ripen their fruit well upon the standards, and the crop of *figs* is often greater upon them than on those trees that are planted against walls, it is a desirable object to plant them either in standards or espaliers. The latter will be the most likely to succeed, if they are managed as in Germany, where they cover the *fig-trees* from the espaliers, and lay them down, covering them in winter with straw or litter; and this covering is gradually removed in the spring. They should not be fastened up again till the end of March.

The principal and most valuable varieties of the common sort of *fig* are the brown or chesnut-coloured Ischia *fig*, the black Genoa *fig*, the small white early *fig*, the large white Genoa *fig*, the black Ischia *fig*, the Malta *fig*, the Murrey or brown Naples *fig*, the green Ischia *fig*, the Madona *fig* commonly called here the Brunswick or Hanover *fig*, the common blue or purple *fig*, the long brown Naples *fig*, the yellow Ischia *fig*, the small brown Ischia *figs*, and the Gentile *fig*. The first, second, third, ninth, and tenth sorts, will ripen their fruits on standards, in a warm situation; but the others require the assistance of walls exposed to good aspects, otherwise their fruit will not ripen in England. Miller.

Figs contain a great quantity of phlegm, a little volatile, alkali salt, and a moderate quantity of oil.

They are moderately nourishing, grateful to the stomach, easier of digestion than any of the other sweet fruits and soften the asperities of the breast, &c. and accordingly are used in medicine, to make gargarisms against disorders of the throat and mouth; and as an ingredient in pectoral decoctions, and in lenitive clysters. They are also applied externally, to soften, digest, and promote maturation.

Figs are dried either by a furnace, or in the sun, having first dipped them in scalding hot ley, made of the ashes of the *fig-tree*. The Latins call them *sarcæ*, or *ficus passæ*, when thus dried.

In this condition they are used both as medicine and food; being both the wholesomer, and easier of digestion, when thus cleared of a quantity of their aqueous and viscid parts.

The best *figs* are the produce of Turky, Italy, Spain, Provence, &c. The islands of the Archipelago yield figs in great abundance; but they are much inferior in goodness to those of Europe. Yet the Greeks in those islands cultivate them with wonderful care and attention, as making the principal food, and a considerable part of the riches of the country.

They have two kinds of *fig-trees*; the first called *ornus*, or the *wild fig tree*; the second, the *domestic fig tree*.

The method of cultivating and ripening these *figs* makes a peculiar art, by the ancients called *caprification*; often spoken of among them in terms of admiration. Some of the modern naturalists have looked on it as a chimera; but Monf. Tournefort has assured us of the contrary, and given us that process, as he learnt it upon the spot. See CAPRIFICATION.

The generation of the *fig* is somewhat anomalous; the parts subservient to the office in other plants, i. e. the flower, not being here apparent. But the anatomy of the fruit helps us out of the difficulty.

Monf. de la Hire the younger, in the Memoirs of the French Academy, shews, that the *fig* is a flower, as well as a fruit. By dissection, it discovers all the essentials of a flower, viz. stamina, apices, and farina fœcundans.

The common dried *figs* afford two very curious phenomena; the one is, that within those which are somewhat decayed, and indeed often in those which appear most sound, there are a peculiar sort of mites, which live on the pulp of the fruit, and we eat millions of these unknowingly in this fruit.

These are different from the common mites, in that they are rounder bodied and more transparent, and are very beautiful little creatures when examined.

The other object is the seed, in which the plantula or animalcule is very elegantly to be seen. For this purpose the largest *figs* must be chosen, for the smaller are commonly such as are pulled off the tree before they are ripe. Out of one of these large and ripe *figs* a fair seed is to be selected; and on cutting this carefully, the whole pulpy part may be separated from the hard husk; and on examining it, there will be found lodged in it a very perfect, and beautiful little plant, consisting of two leaves, and of a part which is to be the root, and another which is to be the stalk; and is fine the true seed of the tree. The pulpy matter of this seed is covered with a delicate thin membrane, and this must be carefully taken off, before the plantule can be seen. After this, all the rest is only a sort of pith, destined to give place and nourishment to the young shoot, before it is committed loose to the earth.

Figured cloth of Otaheite, in the South Sea, is a coarse and harsh cloth, of the colour of the darkest brown paper, made of the bark of a tree which resembles the wild *figtree* of the West Indies. This cloth has the quality of resisting water; and the greater part of it is perfumed, and worn by the chiefs as a morning dress. For the method of manufacturing and colouring this cloth, see Cook's Hawkesworth's *Voyages*, vol. ii. p. 210, &c.

FIGS, in *Antiquity*, were used in divination. See Sycomantia.

FIG, in the *Manege*, is a sort of wart on the truth, and sometimes all over the body of a horse. The *figs* that appear in the truth or tole, make an evacuation of stinking malignant humours, that are very hard to cure.

FIG, *Indian*, in *Botany*. See Prickly Pear.

FIG, *infernal*. See Prickly Poppy.

FIG, *marygold*. See Mesembryanthemum.

FIG, *Pharaoh's*. See Plantain-tree.

Fig-insect, in *Natural History*, a name given by the English to the creature called by the French, after Mr. Reaumur, the *faux puceron*, or *fausse pucerou*, from its very much resembling the pucerou in external appearance, but being extremely different from it when nicely examined. These insects are, when at their full growth, of the bigness of the head of a pin of the largest size, but these are usually found among them several times smaller, down to such as are scarce perceptible to the naked eye. They are found in great plenty on the back, or underside of the leaves of the *figtree*, but they never are seen in clusters like the pucerou.

The body and breast of this insect are green, and the sides of the wings are white, and beset with hairs. This creature has two antennæ or horns, which it can exert at pleasure; but they usually are lodged under the furrows of the wings, and are not to be seen, unless the animal be turned belly upwards; the head also is bent downwards, and the eyes seem directed to look at objects only placed under them.

It has six legs, and a fine small trunk issuing from the extremity of the head; this is but short, and is of a lively green, it is terminated by a sharp point, and has a fine brown filament like a hair, which it thrusts out of the body of the trunk at pleasure, and which seems a sort of organ or organ destined to convey into the body the juices extravasated by the wound and suction of the trunk. The creature usually remains in perfect quietness on the leaf on which it is found; but has this peculiarity in its position, that it is always found with its head resting upon one of the sides of the leaf, and its body on the plain part; by this means the anterior part of the head is raised above the surface of the plain part of the leaf, and the creature can by that advantage move his trunk about at pleasure, and fix it into different parts of the leaf, while his body is perfectly still at the time.

These creatures throw off their skins many times in their growth, the furrows marking the places where their wings are, and the protuberances made by their calves are always large, however young they are examined.

In the months of May and June these insects all become winged, and appear a peculiar species of a four-winged fly, which is remarkable for hopping; but as its hinder legs are not greatly larger than the rest, it leaps but a little way at a time. The body of this fly is green, its wings are bordered with yellow, and its legs are white; it has a trunk of the same nature with that of the creature before its wings of flies, and with this it continues to suck the juices of the leaves of the *figtree* as it did before.

The manner in which these animals propagate their species is not yet known. The pucerons, to which they more approach in figure than to any other animals, have always young ones found within them; but these, if examined in whatever time, never have any such appearance, not even so much as eggs being found in them: it should seem that these eggs are too minute for one inspection, but that they are oviparous, not viviparous animals. Reaumur's Hist. vol. vi. p. 98.

Fig-shell. See Dolium.

Fig-wort, in *Botany*, *Scrophularia*, a genus of the *didynamia angiospermia* class. Its characters are these; the flower has a permanent empalement, and into the parts of the top it has one unequal petal, with a large globular tube; the limb is cloven, five shall parts, the two upper large and erect, the lower one open and spread; and the under one reflexed; it hath four stender declined stamens, two of which are the length of the petal, and two shorter, terminated by twin summits; and an oval germen supporting a single style, crowned by a single stigma; the pericarpium is a two-valved capsule, with two cells, which open at the top, and are filled with small seeds. Linnæus reckons fifteen and Miller eighteen species.

The root and leaves of *scrophularia* have been advised externally as a remedy for the piles, inflammation, scrophulous tumours, and cold ulcers. It is generally made into an ointment for these purposes; but some give it also internally in decoctions. At present they are both among us disregarded.

This root is of a very singular figure, by which it is easily distinguished at sight from all other medicinal roots. It is usually of the thickness of a man's finger, or more, of an oblong figure, nearly as thick at the one end as the other, and full of protuberances on the surface, resembling a kind of little tetticles; and between these there are a great many fibres which strike deep into the ground. The root itself has no great smell, but its taste is somewhat acrid and disagreeable.

Fig-worm worm, in *Natural History*, the name of an insect, which feeds on the leaves of the *scrophularia*, or *fig-wort*, and which is usually esteemed a caterpillar, but is one of those insects called by the French *faiseur chenilles*.

FIGHT. See Battle and Engagement.

FIGHTS, in *Ships*, are the walle-cloths which hang round about but in a fight, to hinder the men from being seen by the enemy.

FIGHTS, *close*, denote those bulkheads seen or made the ship which are pulled for men to stand secure behind, and fire on the enemy, in case of boarding. See Close.

FIGHTING, *running*, in a ship, those we have the enemy do not stand the battle, but are continually chased.

FIGHTWITE, *Fithwita*, in the Saxon times, signified a mulct for making a quarrel, to the disturbance of the peace. *Mulcta et commissum pugnum in perturbationem pacis, quæ in exercitu regis* to *fedderum erat*. Blount and Jacob in transcribing this passage, have inserted 120 tols.

FIGURAL, or Figurate *numbers*, such as do or may represent some geometrical figure, in relation to which they are always considered; as triangular, pentagonal, pyramidal, &c. Numbers.

FIGURATE, or Figurative, that which has a relation to figure, or that teaches under some obscure resemblance.

Thus a *figurative style* is that which abounds in figures. The *figurative* style, F. Bouhours observes, is neither the most just, nor the best. For this reason Cicero directs us to the ancients, who not having yet bethought themselves to use *figurative* expressions, but keeping to the most proper and natural way, have almost all wrote well. *Sunt tamen his veteres, qui nondum audere poterant ea, quæ dicebant, omnia prope pro colore locuti.*

Long use, say the grammarians, renders that proper in all languages, which at first was *figurative*. The same thoughts appear more lively when expressed by a figure, than when in simple terms. The reason is, that *figurative* expressions denote not only the principal matter, but also the emotion and passion of the person who speaks.

Figurative is also much used in speaking of the mysteries and figures of the old law. In this sense manna is said to be *figurative* of the eucharist.

Figurative is allowed in the Greek grammar for what we others use call characteristic, viz. a letter that characterizes certain tenses of the Greek verbs; or that distinguishes and specifies them.

In the first conjugation of the barytonous verbs, the φ is characteristic, or *figurative* of the praeter tense, and the ψ of the future.

Figurative, or Figurative *counter-point*, in *Music*, is that wherein there is a mixture of discords along with the concords. See Counter-point and Supposition.

Where the discords are used as a solid and substantial part of the harmony, the *counter-point* is properly called the harmony of discord.

FIGURE, Figura, in a general sense, denotes the surface or terminating extremes of a body.

All bodies have *some figure*; whence, figurability is generally ranked among the essential properties of body or matter. A body without *figure*, would be an infinite body.

The corpuscular philosophers account for every thing from the

the *figure*, bulks, and motions of the atoms, or primary corpuscles of bodies.

For the *figure* of bodies, considered as objects of sight, fee VISION.

The schoolmen dispute, whether or no the quality of *figure* be the same with that of form; and if they differ, what it is that conftitutes the difference? Boethius will have *figure* only predicated of inanimate bodies, and form of animate. Others extend *figure* to all natural things, and form to all artificial ones; whence the verfe,

Forma viventis, fitti fit figura.

Others apply *figure* indifcreetly to all kinds of bodies, but not in all relations. If only the bare circumference, or circumfcription, be confidered, they call it *figure*: but if the circumference be confidered as endowed with colour, they then call it FORM.

FIGURES, in *Architecture* and *Sculpture*, denote repreſentations of things made in ſolid matters; ſuch as ſtatues, &c.

We ſay, *figures* of brafs, of marble, of ſtucco, of plaſter, &c.

But, in this ſenſe too, the term is more uſually applied to human repreſentations than to other things. Thus we ſay, an equeſtrian *figure*, for a man on horſeback.

Daviler obſerves, that thoſe, either repreſented ſitting, as popes, &c. or kneeling, as on monuments, &c. or laid all along as rivers, &c. are more properly called *ſtatues* than *figures*.

Figures, in *Architecture*, are ſaid to be detached, when they ſtand ſingly, in oppoſition to thoſe compoſitions which are called ENGOURES.

FIGURES, in *Arithmetic*, are the numeral characters; or the characters whereby numbers are expreſſed, or written.

Thus the number of four hundred and fifty is written, or expreſſed, by three *figures*, 450.

The *figures* in authentic uſe are the nine digits, 1, 2, 3, 4, 5, 6, 7, 8, 9, and 0.

Theſe *figures* were firſt brought into Europe by the Moors of Spain, and into England, by Dr. Wallis apprehends, about 1130. See ARITHMETIC and CHARACTER.

However, from ſome ancient dates, ſuppoſed to conſiſt wholly or in part of Arabian *figures*, ſome have concluded, that theſe *figures*, originally Indian, were known and uſed in this country at leaſt as early as the tenth century. The moſt ancient date diſcovered by Dr. Wallis was that on a chimney piece, at Helmdon, in Northamptonſhire, M.133, i. e. 1133. Other dates diſcovered ſince, are 1090, at Colcheſter, in Eſſex, 1056, with the Roman M for a thouſand, at Widgel-Hall, near Buntingford, in Hertfordſhire, 1011 on the north front of the pariſh-church of Rumſey in Hampſhire, and 975 over a gate way at Worceſter. Dr. Ward has urged ſeveral objections againſt the antiquity of theſe dates. As no example occurs of the uſe of theſe *figures* in any ancient manuſcript, earlier than ſome copies of Johannes de Sacro Boſco, who died in 1256, he thinks it ſtrange, that workmen ſhould have made uſe of the *figures* ſo long before they appear in the writings of the learned; and he alſo diſputes the fact. The Helmdon date, according to him, ſhould be 1233; the Colcheſter date 1490; that at Widgel-hall has in it no Arabian *figures*, the 1 and 6 being I and C, the initial letters of a name; and the date at Worceſter, he ſuppoſes to conſiſt of Roman numerals, and to be really MXV. Martyn's Abridg. of Phil. Tranſ. vol. iv. p. 420, &c.

FIGURE, in *Aſtrology*, a deſcription, or draught, of the ſtate and diſpoſition of the heavens, at a certain hour; containing the places of the planets and ſtars, marked down in a *figure* of twelve triangles, called *houſes*.

This is alſo called a HOROSCOPE and THEME.

FIGURE, *of an eclipſe*, in *Aſtronomy*, denotes a repreſentation of the path or orbit of the ſun, and the moon, during the time of the eclipſe, upon paper; with the number of digits eclipſed, and the beginning, middle, and end, of darkneſs.

FIGURE *of the diameter*. The rectangle under any diameter, and its proper parameter, is in the ellipſis and hyperbola called the *figure of that* DIAMETER.

FIGURE, *or Deſcription*, of the full moon, ſuch as viewed through a teleſcope with two convex glaſſes, is of conſiderable uſe in obſervations of eclipſes, and conjunctions of the moon with other luminaries. In this *figure* of the moon are repreſented the macules, or ſpots, of the moon, marked by numbers, beginning with the ſpots, which uſually enter firſt within the ſhade at the time of the great eclipſes, and alſo emerge the firſt.

FIGURE, in *Conics*, denotes the rectangle, made under the latus rectum and tranſverſum, in the hyperbola and ellipſis.

FIGURE, in *Dancing*, denotes the ſeveral ſteps which the dancers make in order, and cadence; conſidered as they mark certain *figures* on the floor.

FIGURES, in *Fencing*, are the divers guards, poſtures, attitudes or diſpoſitions, of the body, arms, or ſword. See FENCING.

FIGURE, in *Fortification*, is the plan of any fortified place; or the interior ENCLOSURE, &c.

When the ſides and angles are equal, it is called a *regular* or *juſtum* inæquale, an *irregular figure*.

FIGURE, in *Geometry*, is applied to the extremes of points, lines, or numbers, thrown, or caſt at random, in the combinations or variations whereof the laws of this art found their fundamental demonſtrations.

FIGURE, in *Geometry*, denotes a ſurface included, or circumſcribed with one or more lines.

Such are triangles, ſquares, polygons, circles, ellipſes, &c.

Wallis defines *figure* a continuum terminated by a perimeter. In which ſenſe *figure* is applicable both to ſuperficies and ſolids. In the former caſe, the perimeter is of lines; in the ſecond, of ſurfaces.

Figures are either rectilineal, curvilineal, or mixt, according as the perimeter conſiſts of right lines, curve lines, or both.

The ſuperficial parts of a *figure* are called its *ſides*; the loweſt ſide, its *baſe*; and the angle oppoſite to the baſe, the *vertex*.

The height of a figure is the diſtance of the vertex from the baſe.

FIGURE, in *Grammar*, is an expreſſion that deviates from the common and natural rules of grammar: either for the ſake of elegance or brevity.

The beſt grammarians only reckon four *figures*; the ELLIPSIS, PLEONASM, SYLLEPSIS, and HYPERBATON.

Others add two more; viz. ANTIPTOSIS, and ENALLAGE.

FIGURE, in *Heraldry*, a bearing in a ſhield. Of theſe *figures* there is almoſt an infinite variety: ſome are natural; ſuch as the celeſtial *figures* of the ſun, moon, ſtars, &c. and their parts; the elementary ones, warmth, &c. and their parts; animals, as lions, dogs, ſtags, boars, &c. and their parts; birds, as eagles, ſwans, ſtarlings, pelicans, &c. and their parts; fiſhes, as dolphins, whales, ſturgeons, trouts, &c. and their parts; reptiles, and inſects, as tortoiſes, ſerpents, grashoppers, &c. and their parts; vegetables, as trees, plants, flowers, herbs, &c. and their parts; and ſtones, as diamonds, rubies, pebbles, rocks, &c. Theſe charges, as well as ordinaries, have divers attributes or epithets, which expreſs their qualities, poſitions, and diſpoſition. Thus, the lion is ſaid to be *in his glory, aſſiſted*, &c. the moon *in her complement, increſcent*, &c. Animals are ſaid to be *rampant, paſſant*, &c. Birds have alſo their denominations; fiſhes are deſcribed to be *hourſed, naiant*, &c. Beſides theſe natural *figures*, there are alſo artificial *figures*; the principal of which are warlike inſtruments, as ſwords, arrows, battering rams, gauntlets, helmets, ſpears, poleaxes; ornaments uſed in royal and religious ceremonies, as crowns, coronets, mitres, wreaths, croſiers; towers, caſtles, arches, columns, plummets, battlements, churches, portcullis, borrowed from architecture and fortification; and ſhips, anchors, rudders, pendants, ſails, oars, maſts, flags, gallies, lighters, &c. derived from navigation; all theſe bearings have different epithets, denoting their poſition, ſtructure, &c.

There are likewiſe chimerical or imaginary *figures* uſed in heraldry, that are the reſult of fancy and caprice; ſuch as centaurs, hydras, phœnixes, griffins, dragons, &c. Porny's Elem. Herald. p. 132, &c. 172, &c.

FIGURE, in *Logic*, denotes a certain diſpoſition of the terms of a ſyllogiſm; particularly of the medium, with regard to the extremes.

Hence it follows, that there are as many *figures* of ſyllogiſm, as there are different connexions of the extremes with the medium; ſo that, though the ſyllogiſm ordinarily only reckon three, yet a fourth might be admitted.

In the *firſt figure* the medium or middle term is the ſubject of the major propoſition, and the predicate of the minor. This contains four moods, and applies to the proof of all ſorts of queſtions, whether univerſal or particular, affirmative or negative. In the *ſecond figure* the middle term is the predicate of both the premiſes, and this contains four moods, admitting only of negative concluſions.

The *third figure* requires that the middle term be the ſubject of both the premiſes, and has ſix moods, admitting only of particular concluſions. The ſpecial rules of theſe three *figures* are the following: in the firſt, the major propoſition muſt always be univerſal, and the minor affirmative; in the ſecond alſo the major muſt be univerſal, and one of the premiſes, together with the concluſion, muſt be negative; in the third *figure* the minor muſt be affirmative, and the concluſion always particular.

In

In the *fourth figure*, called by the Peripatetics the *indirect*, and by others, the *Galenical figure*, as varying too much from the natural form, the middle term is predicated in the major proposition, and subjected in the minor. Some logicians will allow this to be nothing else but a mere inversion of the *first figure*. It has five moods. Watts's Logic, part iii. chap. 2 § 3.

FIGURE, in the *Manufactures*, is applied to the various designs represented or wrought on velvets, damasks, taffaties, fattins, and other ſtuffs and cloaths.

The moſt uſual *figures* for ſuch deſigns are flowers, imitated from the life; or groteſques, and compoſitions of pure fancy. Repreſentations of men, beaſts, birds, and landſkips, have only been introduced ſince the taſte for the Chineſe ſtuffs, particularly thoſe called *ſarſes*, began to prevail among us.

It is the woof of the ſtuff that forms the *figures*; the warp only ſerves for the ground. In working *figured* ſtuffs, there is required a perſon to ſhew the workman how he muſt raiſe the threads of the warp, to repreſent the *figure* of the deſign with the woof, which is to be paſſed acroſs between the threads that are raiſed. This ſome call *reading the* DESIGN.

For the *figures in tapeſtry, brocade*, &c. See TAPESTRY, &c.

For thoſe given by the *enamellers, printers*, &c. See CALENDER, &c.

FIGURE, *Figure, Type*, in the *Ancient Muſic*, is uſed for the different diſpoſitions of the tones and ſemitones in a conſonance.

FIGURE, *apparent, in Optics*, that figure, or ſhape, which an object appears under when viewed at a diſtance, being often very different from the true figure; for a ſtraight line viewed at a diſtance may appear like a point; a ſurface as a line; and a ſolid as a ſurface: and each of theſe of different magnitudes, and the two laſt of different *figures*, according to their ſituation with regard to the eye. Thus an arch of a circle may appear a ſtraight line; a ſquare or oblong, a trapezium, or even a triangle; a circle, an ellipſis; angular magnitudes, round; a ſphere, a circle, &c.

Alſo any ſmall light, as a candle, ſeen at a diſtance in the dark, will appear magnified, and farther off than really it is. Add to this that if ſeveral objects are ſeen at a diſtance, under angles that are ſo ſmall as to be inſenſible, as well as each of the angles ſubtended by any one of them, and that next to it; then all theſe objects will appear not only to be contiguous, but to conſtitute and form but one continued magnitude.

FIGURE, in *Painting* and *Deſigning*, denotes the lines and colours, which form the repreſentation of a man, or other animal.

But the term *figure* is in a more immediate and peculiar manner underſtood of human perſonages: thus, a painter is ſaid to be full of *figures*, when it abounds with repreſentations of men; and a landſcape is ſaid to be without *figures*, when there is nothing but trees, plants, mountains, &c.

FIGURE, is alſo applied to repreſentations, or images of things in prints, &c.

Some readers chuſe to have the *figures*, eſpecially the mathematical ones, in wood, for the convenience of having them immediately annexed to the matter they refer to: others rather chuſe to have the pains of turning over, and having recourſe to another part of the book, that they may have the *figures* more neat and accurate on copper.

The author of a collection of diſſertations, printed at Paris, in 1715, ſhews, in the firſt diſſertation on the Hebrew medals, p. 66. that the Jews were allowed to make any kind of *figures*, or images of trees, plants, flowers, buildings, &c. but not thoſe of animals, or of the ſun, moon, and ſtars.

FIGURES, *brimſtone*. See BRIMSTONE.

FIGURES, *caſting of*. See CASTING.

FIGURE *circumciſed, and uncircumciſed*. See CIRCUMSCRIBING, and INSCRIBED.

FIGURES, *equal*. See EQUAL.

FIGURE, *equilateral*. See EQUILATERAL.

FIGURES, *plain*. See PLAIN.

FIGURE, *regular* and *irregular*. See REGULAR and IRREGULAR.

FIGURES, *ſimilar*. See SIMILAR.

FIGURE, in *Rhetoric*, is a phraſe, or turn of ſpeech or diſcourſe, more beautiful and emphatical than what is uſed in common or ordinary ſpeaking.

Figures, by the Greeks called σχηματα, *ſchemata*, are the enrichments of diſcourſe, and we only uſe them when raiſed and moved with the conſideration of ſomething extraordinary.

There are two kinds of *figures*; the one of *ſentences*, and contained in the ſenſe itſelf, without any immediate dependence on any particular words; the other are only in the words themſelves.

FIGURES *of ſentence, or the*, ſame are principally adapted for reaſoning and inſtruction, and others to move the paſſions.

Among the ancients, Demoſthenes is moſt celebrated for expreſſing the force and energy of the former, and Iſocrates excelled in the beauties and delicacies of the latter.

Cicero lays ſo great ſtreſs on theſe *figures*, that he repreſents them as the brighteſt parts of oratory; and makes the power and efficacy of the art to depend in a great meaſure on a thorough knowledge and application of them.

Of the firſt kind the moſt conſiderable are ſix; viz. PROLEPSIS, or *anticipation*; SYNPHORA, or *ſubjection*; ANACOINOSIS, or *communication*; EPITROPE, or CONCESSION; *parabole*, or SIMILITUDE; and ANTITHESIS, or *oppoſition*. Thoſe of the ſecond kind are EPANORTHOSIS, or *correction*; PARALEPSIS, or *omiſſion*; PARRHESIA, or *reproachful*; APARITHMESIS, or *enumeration*; ENERGASIA, or *expreſſion*; HYPOTYPOSIS, or *imagery*; APORIA, or DOUBTING; APOSIOPESIS, or *concealment*; *erotefis*, or INTERROGATION; *ecphonefis*, or EXCLAMATION; EPIPHONEMA, or *acclamation*; APOSTROPHE, or *addreſs*; PERSONARIA, or *the fiction of a perſon*.

Of FIGURES *of words*, ſome are tropes, or tranſlations of words from their proper ſignification, to ſome more remote and extraordinary one. See TROPE.

Others are *figures of words*, more properly ſo called; and that tropes, being ſo inherent in the words, that upon changing of the words, or ſometimes only their ſituation, the *figure* is deſtroyed: as in *manners ſuit women*, where the *figure* would be loſt, if inſtead of *manners* you ſhould put *fruit*.

Thus alſo, *to live all reaſon of life, is in effect to live life*; the *figure* is loſt by changing the order of the words; as, *to live all reaſon of life, is to live life in effect*.

The principal of theſe verbal *figures* may be arranged into three claſſes; ſuch as conſiſt in a deficiency of words, in a redundancy, or a repetition. To the firſt claſs belong the ELLIPSIS and ASYNDETON. Under the ſecond diviſion are comprehended the PLEONASMUS and POLYSYNDETON. The third kind of verbal *figures* include thoſe by which the ſame word in ſound, or ſenſe, is repeated; or one of a like ſound or ſignification, or both. Of the firſt ſort in this diviſion there are ten, called ANTANACLASIS, FLUCE, EPIZEUXIS, CLIMAX, ANAPHORA, EPISTROPHE, SYMPLOCE, EPANALEPSIS, ANADIPLOSIS, and EPANODOS. To the ſecond claſs belong the PARONOMASIA, the HOMOIOTOTON, the SYNONYMIA, and DERIVATION; the two firſt of which reſpect words that are ſimilar in ſound only, the third in ſenſe, and the laſt in both. With regard to the proper uſe of *figures*, we may obſerve, that they ſhould always be accommodated to the ſentiments, and riſe in proportion to the images deſigned to be conveyed by them; it is alſo better, in general, to be nervous than copious, that the images, by their cloſer union, may impreſs the mind with greater energy, though in ſuch *figures* as are deſigned for ornament or illuſtration, a more diffuſive way of painting is ſometimes agreeable. The too frequent uſe of *figures* ſhould be avoided; and they ſhould be ſo interwoven in a diſcourſe as not to render the ſtyle rough and uneven, ſometimes high and at other times low; now dry and jejune, then pompous and florid. In every caſe they ſhould ſeem to riſe more from nature than *art*, to offer themſelves rather than to be the effect of ſtudy. Ward's Orat. Lect. 30, 31, 32, 33, 34.

Of theſe the principal are repetition, converſion, complexion, gradation, ſynonymy, polyſyndeton, and polyptoton, reticency, diſjunction, ſimilitude, paronomaſy, and tranſition. See each *figure* under its proper article, as METAPHOR, &c.

To FIGURES *of profody* belong the SYNALOEPHA, ECTHLIPSIS, CHASIS, SYNERESIS, DIERESIS, SYSTOLE, and DIASTOLE.

FIGURE is uſed, in *Theology*, for the myſteries repreſented or delivered obſcurely to us under certain types or actions in the Old Teſtament.

Thus manna is held a *figure* or type of the euchariſt; and the death of Abel a *figure* of the ſuffering of Chriſt.

Many divines and critics contend, that all the actions, hiſtories, ceremonies, &c. of the Old Teſtament, are only *figures*, types, and prophecies, of what was to happen under the New. The Jews are ſuppoſed to have had the *figures* or ſhadows, and we the ſubſtance.

FIGURE is alſo applied in a like ſenſe to prophanic matters as the emblems, enigmas, fables, ſymbols, and hieroglyphics, of the ancients.

FIGURED, in *Heraldry*, is an epithet applied to thoſe bearings which are depicted with a human face.

FIGURED, in the *Manufactures*. A *figured* CAMLET, ſtuff, tabby, &c. is that whereon there are divers deſigns of flowers, figures, branches, &c. impreſſed by means of hot irons.

FIGURED *ribbands* firſt came into faſhion about the year 1680. The method of performance was by ſucceſſively applying ſteel plates engraven with divers ornaments, as flowers, birds, groteſques, &c.

But one Chandelier, a ribband-maker of Paris, invented a much better and readier way of doing it, by a machine not unlike the flatter uſed in coining to flatten the pieces of metal, only much ſimpler.

The principal parts thereof were two ſteel cylinders, engraven with the figures intended to be repreſented. Theſe cylinders were placed over each other like the rolls of a rolling-preſs, having each of them, at one of its extremes a little dented wheel, one of which catching into the other, the whole was put in motion by means of a winch or handle faſtened to the firſt.

The machine thus prepared, the workman heats the cylinders, and places the ribband in the little place remaining between the two, which he contracts yet farther by a ſcrew that preſſes the upper part down upon the lower: then turning the rolls by the handle, a whole piece of RIBBAND was figured in leſs time than a ſingle yard could be done in the ordinary way.

FIGURED *velvet*. See VELVET.

FILACEOUS, in *Botany*, a term applied to ſuch roots of plants as are full of fibaments. See FILAMENT.

FILACIUM. *See* FILE.

FILAGO, in *Botany*. There are ſeveral ſpecies of this genus, ſome of which grow naturally on barren land in moſt parts of England. They are called by ſome cotton-weed; by others cud-weed, their leaves being white, and when broken, appearing to conſiſt of cottony threads. Moſt botaniſts have ranged them under the genus of *gnaphalium*. See CUDWEED. LINNÆUS makes the *filago* a diſtinct genus of the *ſyngeneſia polygamia neceſſaria* claſs, with a naked receptacle, no down, an imbricated calyx, and ſmall female flowers placed between the folds of the calyx.

FILAMENT, in *Medicine, Anatomy, Natural Hiſtory, &c.* a term uſed in the ſame ſenſe with FIBRE for thoſe fine threads whereof fleſh, nerves, ſkins, plants, roots, &c. are compoſed.

FILANDERS, in *Farkery*, a diſeaſe in hawks, &c. conſiſting of filaments or ſtrings of blood coagulated and dried, occaſioned by a violent rupture of ſome vein, by which the blood extravaſating, hardens into the figures above mentioned, to the great annoyance of the reins, hips, &c.

The word is French, *filandres*, formed from *fil, thread*.

FILANDERS are alſo a ſort of fine ſmall worms which greatly incommode the hawk in the gorge, and about the heart, liver, and lungs: but which, on ſome occaſions, are ſuppoſed to be of ſervice, and to feed on the ſuperfluities of certain parts. See BACK-*worm*.

There are four kinds of theſe *filanders* or *vermicels*. The firſt, in the gorge or throat; the ſecond, in the belly; the third, in the reins; the fourth are called needles, on account of their exceeding ſmenels. The ſymptoms that diſcover the diſeaſe are the bird's gaping frequently, ſtraining the fiſt or perch with her pounces, croaking in the night, ruffling her train, rubbing her eyes, wings, noſtrils, &c. As the worms are very reſtleſs, the bird is frequently endeavouring to caſt them up; and in opening its mouth, you will readily diſcover them. From the throat, &c. they will aſcend to the larynx, brain, &c. and finally over the whole body.

The ordinary cauſe is bad food. The proper remedy, they ſay, is not by killing them, for fear of impoiſoning from their corruptions; but chiefly by ſtupefying them, that they may be offenſive but ſeldom.

This is beſt effected by making the bird ſwallow a clove of garlic, after which the will feel nothing of the *filanders* for forty days. Others uſe rue, worm-ſeed, aloes, vetvain, ſaffron, &c.

FILAWS, among the modern Ægyptians, villages inhabited by the original natives of the country.

FILAZER, FILACER, FILIZER, an officer in the court of common pleas, ſo called becauſe he *files* the writs wherein he makes out proceſs.

Of theſe there are fifteen in the ſeveral diviſions and counties of England. They make out all writs and proceſs upon original writs, iſſuing out of the chancery as well real as perſonal and mixed, returnable in that court. In actions merely perſonal, where the defendants are returned ſummoned, they make out pones or attachments, which being returned and executed, if the defendant appears not, they make out a diſtringas, and ſo *ad infinitum*, or till he does appear.

If he be returned *nihil*, then proceſs of capias infinite if the plaintiff will; or after the third capias the plaintiff may proceed to outlawry in the county where his original is grounded, and may have an exigent with proclamation.

The *filazers* likewiſe make out all writs of view in real actions where the view is prayed; and upon replevins and recordatis, writs of returno habendo, ſecond deliverance, and writ of withernam. In real actions they make out writs of grand and petite cape before appearance.

They enter all appearances and ſpecial bails upon any proceſs made by them. They make the firſt ſcire facias upon ſpecial bails, writs of habeas corpus, diſtringas nuper vicecomitem vel ballivum, and alocer tectum; and all ſuperſedeaſes, upon ſpecial bail or appearance, &c. writs of habeas corpus cum cauſa upon the ſheriff's return that the defendant is detained with other actions, and writs of adjournment of a term, in caſe of peſtilence, war, or public diſturbance.

I till an order of court made 13 Jac. I. which limited the *filazers* to all matters and proceedings before appearance, and the prothonotaries to all after, they alſo entered declarations, imparlances, judgments, and pleas, whereto a ſerjeant's hand was not requiſite, and made out writs of execution and divers other judicial writs after appearance.

FILBERDS, or FILBUDS, the beſt ſort of ſmall nuts, proper for planting in orchards or gardens.

They are raiſed from nuts ſet in the earth, or ſuckers from the roots of an old tree, or they may be grafted on the common HAZEL-*nut*.

They delight in a fine mellow, light ground, but will grow almoſt any where, eſpecially if defended from violent and cold winds.

The tree is eaſily propagated, bears well, and is of two ſorts, the *white* and the *red*, but the former is the beſt.

FILE, an inſtrument of ſteel, cut in little hatches or furrows, uſed by the workmen in metals, to ſmooth, poliſh, and otherwiſe faſhion the ſame.

The word is French, *file*, literally ſignifying a long ſeries or ſucceſſion of any kind of things, of *fil, thread*.

Files bear a near reſemblance to raſps: the only difference between them is, that the former are cut with edged tools, and the latter are punched with pointed ones. See RASP.

The *file* is a principal inſtrument in all the kinds and parts of ſmithery. It ſhould be forged of the beſt ſteel; after which, rubbing it with greaſe, to make it more ſoft under the chiſſel, they cut it with chiſſels and a mallet, this and that way, and of this or that depth, according to the grain or tooth required.

After cutting the *file*, it remains to be tempered; which, being the principal myſtery of making the *file*, will deſerve to be particularly deſcribed.

Files then are tempered with a compoſition of chimney-ſoot, very dry and hard, diſſolved and worked up with urine and vinegar, to which is added common ſalt: the whole is to be reduced to the conſiſtence of muſtard.

The *files* being cut, and rubbed over with vinegar and ſalt to ſcour off the greaſe laid on for the forging, they cover them over with this compoſition; and having laid ſeveral of them together in a packet, and covered them in loam, they put them in a charcoal fire; from which they are taken out again by that time they have acquired a cherry-colour, which is known by a little reſt rod of the ſame ſteel put in along with them. Upon taking them out, they caſt them into the coldeſt ſpring water they can get.

Iron *files* require a more intenſe heat than ſteel ones. When the *files* are cold they clean them with charcoal, a rag, &c. to take away any of the ſoot or faces left in the cuttings; then drying them before the fire, they put them up carefully in a box of wheat bran, to keep them from ruſting.

Files are of different forms, according to the diffecent uſes and occaſions they are made for. Thoſe in common uſe are the ſquare, flat, triangular, half-round, round, thin *file*, &c. all which are made of different ſizes, as well as different cuts and degrees of fineneſs, to take place according as the work is more or leſs advanced, ſome cutting faſter, as the *rough-toothed file*, &c. others more ſlowly, as the *fine-toothed file*, &c.

FILE is alſo a thread of wire whereon writs or other exhibits in courts or offices are faſtened or filed, for the more ſafe keeping and ready turning to the ſame.

A *file* is a record of the court, and the filing of the proceſs of a court makes a record of it.

FILE, or *label*, in *Heraldry*, a bearing repreſented in *Tab. Herald. fig.* 23. though ſometimes of more, and ſometimes of fewer points, being the difference or diſtinction of the eldeſt ſon.

It is ſometimes alſo borne as a charge in a coat armour, of which Guillim gives many inſtances; but it is often the difference or mark of diſtinction which the elder bro-

ther bears in his coat during his father's life.

Some distinguish *file* and *label*, calling the *file* the upper horizontal line, and the *label* the points which issue from it.

FILE *of three*, or more, *labels*. See LABEL.

FILE, in a *Military Sense*, is a row of men ftanding one behind or below another from front to rear.

Or, *file* is a line or feries of foldiers, placed one before another, and thus compoſing the DEPTH of a battalion or ſquadron. The *files* which bind the right and left are called the flanks.

They ſay, *cloſe the files*; that is, bring the men nearer each other. *Double the files*; that is, double the depth of the battalion, and diminiſh its breadth or front by one half. The laſt or hindermoſt perſon is ſaid *to bring up the file*. To *file off*, is to wheel off from marching in a ſpacious front, and to march in length by *files*.

FILE-*leaders*, are the foremoſt men in each *file*.

FILE-*leaders*, *half*, are the men of the fourth rank; the fourth, fifth, and ſixth ranks being called the *rear half-files*, as the firſt, ſecond, and third are the *front half-files*.

FILIAL, ſomething belonging to the relation of a ſon.

The divines uſually diſtinguiſh between a ſervile and a *filial* fear. The moſt abandoned have a ſervile fear of God, ſuch as that of a ſlave to his maſter; but not a *filial* fear, i. e. a fear reſulting from love and reſpect.

FILICULA, in *Botany*. See *Dwarf* FERN.

FILIGRANE, or FILIGREE, *work* a kind of enrichment on gold or ſilver, wrought delicately in manner of little threads or grains, or both intermixed.

The word is compounded of *fil* or *filum*, *thread*, and *granum*, *grain*.

In Latin it is called *filorum elaboratum opus*, *argentum*, *aurum*.

We have vaſes, &c. of *filigree* work. The term has been lately applied, to ornamental works, formed, as fancy directs, of ſtrips of paper, differently coloured, rolled into various figures, and artfully combined.

FILING, one of the principal operations in ſmithery, &c. ſucceeding to forging.

The coarſer cut files are always to be ſucceeded by finer; and in all the kinds the rule is to lean heavy on the file in ſhuffling it forward, becauſe the teeth of the file are made to cut forwards; but in drawing the file back again for a ſecond ſtroke, it is to be lightly lifted juſt above the work, becauſe it cuts not coming back.

The rough or coarſe-toothed file (which, when large, is called a rubber) ſerves to take off the unevenneſſes of the work left by the hammer in forging.

The baſtard-toothed file is to take out the too deep cuts and file-ſtrokes made by the rough file; the fine-toothed file takes out the cuts or file-ſtrokes the baſtard-file made; and laſtly, the ſmooth file thoſe left by the fine file.

In this order the files of ſeveral cuts are to ſucceed each other till the work is as ſmooth as it can be filed; after which it may be made yet ſmoother with emery, tripoli, &c. See POLISHING.

FILIPENDULA, in *Botany*. See DROPWORT and SPIRÆA.

FILIUS *ante patrem*, q. d. the ſon before the father, a denomination applied by botaniſts and florifts to plants whoſe flowers come out before their leaves. Such are the ſeveral ſpecies of colchicum or meadow-ſaffron, the colt's-foot, butterbur, &c.

FILIX, in *Botany*. See FERN.

To FILL, in the *Sea-language*, is to brace the ſails in ſuch a manner, that the wind entering their cavities from behind, diſtends them, ſo as to advance the ſhip in her courſe, after the ſails had been for ſome time ſhivering or braced back.

FILLAR, or THILLER, *Horſe*. See THILLER.

FILLET, in *Anatomy*. See FRÆNUM.

The word is French, *fil*, formed of *filum*, *thread*.

FILLET, or FILET, in *Architecture*, denotes a little ſquare member or ornament uſed in divers places and on divers occaſions, but generally as a ſort of corona over a greater moulding. See *Tab. Arch.* fig. 21. N° 1.

The *fillet* is the ſame with what the French call *regle*, *bande*, and *bandelette*; the Italians, *liſtra*, or *liſtello*.

FILLET, in *Botany*. See THREAD.

FILLET, *tenicla*, in *Heraldry*, a kind of orle or bordure, containing only a third or fourth part of the breadth of the common BORDURE.

It is ſuppoſed to be withdrawn inwards, and is of a different colour from the field. It runs quite round, near the edge, as a lace over a cloak.

FILLET is alſo uſed for an ordinary drawn like the bar from the ſiniſter point of the chief acroſs the ſhield, in manner of a ſcarf; though it is ſometimes alſo ſeen in the ſituation of a bend, feſſe, croſs, &c.

According to Guillim, the *fillet* is a fourth part of the chief, and is placed in the chief point of the eſcutcheon.

FILLET is alſo uſed among *Painters*, *Gilders*, &c. for a little rule and reglet of leaf-gold, drawn over certain mouldings; or on the edges of frames, paunels, &c. eſpecially when painted white, by way of enrichment.

FILLETS, in the *Manege*, are the loins of a horſe, which begin at the place where the hinder-part of the ſaddle reſts.

FILLY, a term among *Horſe-dealers*, to denote the female or mare colt. See FOAL.

FILM, a thick ſkin or peliicle.

In plants it is often uſed for that thin woody ſkin which ſeparates the ſeeds in the pods, and keeps them apart.

FILM, *white*, on *the eye of a horſe*, may be removed by lifting up the eye-lid, after the eye has been waſhed with wine, and ſtroking it gently with the thumb with wheat-flour: common ſalt and ſalt of lead, beaten fine, and put into the eye, are proper to conſume a *film*; or the horſe's eye may be waſhed with the ſpittle in the morning, faſting, having firſt put a little ſalt into your mouth: but there is nothing ſo effectual as ſal ammoniac, beaten and put into the eye, and repeated every day till the *film* is gone.

FILTER, or FILTRE, in *Chemiſtry*, &c. a piece of woollen cloth, linen, paper, or other matter, ſome of which are in the form of bellow inverted cones, uſed to ſtrain or ſtrain liquors through.

The *ſtove* has the ſame uſe and effect with regard to liquids that the ſieve or ſearce has in dry matters.

Filtres are of two ſorts: the firſt are ſimple pieces of paper or cloth, through which the liquid is paſſed without farther trouble.

The ſecond are twiſted up like a ſkain or wick, and firſt wetted, then ſqueezed, and one end put in the veſſel that contains the liquor to be filtrated; the other end is to be out, and hung down below the ſurface of the liquor; by means hereof the pureſt part of the liquor diſtils drop by drop out of the veſſel, leaving the coarſer part behind.

This *filter* or *ſtrainer* acts as a ſiphon.

FILTER is alſo a charm, ſuppoſed to have a virtue of inſpiring love.

The word is derived from ποτος, which ſignifies the ſame thing, of πινω, *bibo*, *I drink*.

The Greeks, when their love was without ſucceſs, had ſeveral arts to procure the affections of their beloved. The Theſſalian women were famous for their ſkill in this, as well as other magical practices. The means whereby it was effected were of divers ſorts: it was ſometimes done by potions, called ποτα, which are frequently mentioned in authors of both languages. Juvenal ſpeaks thus:

Hoc magicis offert carmen, hic Theſſala vendit
Philtra, quibus valeant mentem vexare mariti.

Their operations are violent and dangerous, and commonly deprived ſuch as drank them of their reaſon. Plutarch and Cornelius Nepos report, that Lucullus, the Roman general, firſt loſt his reaſon, and afterwards his life by one of them. Lucretius, the poet, ended his life by the ſame way; and Caius Caligula, as Suetonius reports, was driven into a fit of madneſs by a *philtre* given him by his wife Cæſonia, which ſtory is mentioned by the ſame poet. Ovid likewiſe aſſures us, that this was the uſual effect of ſuch potions.

The ingredients they were made of were of divers ſorts, ſeveral of which, applied by themſelves, were thought effectual.

FILTRATION, the act of paſſing any liquor through a filtre, called alſo *colature*, *percolation*, and *tranſcolation*. See FILTER.

The end of *filtration* is of two kinds; the one to free fluids from any ſolid bodies of a feculent nature with which they are mixed; and the other to ſeparate any precipitated powder or other ſolid body from ſuperfluous fluids; and the means muſt be varied accordingly. Such liquors as are incorporated with particles that adhere to them are rendered capable of *filtration* by coagulating and collecting the heterogeneous parts. This is effected either by boiling or by mixing whites of eggs and boiling them with the turbid liquors. See CLARIFICATION.

The moſt commodious way of *filtrating* is by whited-brown paper faſtened over the mouth or aperture of a funnel; the ſmalneſs of the pores of this paper admits only the finer parts through, and keeps the reſt behind. There are alſo *filtrations* through ſand, pulverized glaſs, &c. Spirits of vitriol, ſalt, and nitre, are *filtrated* through a quantity of beaten glaſs in the bottom of a funnel.

Filtration is alſo performed by a woollen or linen bag, called Hippocrates's ſleeve: the choice of theſe muſt be directed by the liquor to be *filtered*.

Dr. Papin contrived a method by which *filtrations* through cap-paper might be made ſuddenly, and with great quantities of liquor, by the help of the air-pump. For this purpoſe he made uſe of the following contrivance: A A (*Tab.* II. *Hydraulics*, &c. *fig.* 9.) is a glaſs receiver,

ceiver, BB a cover fitted to it, CCC is a pipe forming the communication between the receiver AA and the air-pump, DD a shallow veſſel full of little holes, EEE a pipe that makes the communication between the veſſel DD and the receiver AA, FF a veſſel to contain the liquor to be filtrated, and GG the plate of the pump. When this inſtrument is uſed, the ſhallow veſſel DD ought to be tied about firſt with linen cloth, and then with cap-paper, ſo that no liquor may get into the holes of the ſaid veſſel but through the cap-paper, and linen cloth; this muſt be wholly placed within the liquor to be filtrated: let the air be extracted by means of the air-pump out of the veſſel AA. Then the liquor in the veſſel FF muſt be drawn through the cap-paper, and the linen cloth into the veſſel DD, and from thence through the pipe EEE into the veſſel AA; and this operation muſt be quick, on account of the great preſſure of the atmoſphere that drives the liquor; beſides, the ſediment of the liquor ſubſiding at the bottom of the veſſel FF will not be ſo apt to ſtop the pores of the cap-paper as in ordinary *filtrations*. Birch's Hiſt. of the Royal Society, vol. iv. p. 360, &c.

The ſecretion of the divers juices in the body from the maſs of blood ſeems to be little elſe but *filtration*. Pitcairn, and other late authors, hold that the diverſity of *filtration* does not depend on the different configurations of pores, but on their different ſizes or diameters.

Springs, alſo, ſeem to be raiſed from the ocean by the ſame principle of *filtration*.

FILTRATION, in *Pharmacy*, is chiefly concerned in tinctures; as when ſome portion is drawn from the ingredients or ſuſpended in the tincture which is not neceſſary thereunto, but diſturbs and renders the reſt unpleaſant both to the palate and ſight. Beſides this, there is a *filtration* which has much tortured the philoſophy of ſome ages to account for; this is that performed by the aſcent of the finer parts of a liquor up a cord or ſkein of cotton, or ſuch like matter, which is contrived to drop over another veſſel and leave the groſſer behind.

After the ſame manner it is, without doubt, that the humidity of the earth is drawn up into the ſubſtance of the roots of vegetables, which we know conſiſts of long and very minute fibres, ſo diſpoſed as to form a great number of tubular interſtices; theſe act in the nature of this ſort of *filtre*, and attract the juices and moiſture appointed for the nutriment and increaſe of the plant.

Some ſay, that the cauſe of this aſcent is becauſe the liquor ſwells thoſe parts of the filter that touch it, by entering into the pores of the threads which compoſe it, whereby they riſe up, touch, and wet thoſe next above them; and theſe again the next threads; and ſo on to the brim of the veſſel, when the liquor runs over, and deſcends in the other part of the filter which hangs down by its own natural gravity.

But this account is liable to many objections, eſpecially as liquors riſe after the ſame manner in glaſs tubes much above the ſurface of the liquor they are immerſed in, where the glaſs cannot be imagined thus to ſwell.

Others account for it, by conſidering every filter as compoſed of a great number of long, ſmall, ſolid bodies, which lie very cloſe together; ſo that the air getting in between them loſes much of its preſſure, and cannot gravitate ſo ſtrongly as it doth on the fluid without them; the conſequence is, that the parts of the water between the threads of the filter muſt be preſſed upwards, and aſcend till they come ſo high, as, by their weight, to counterbalance the general preſſure on the other parts of the ſurface of the water.

Laſtly, the retainers to Sir Iſaac Newton's philoſophy deduce the phenomenon from the principle of attraction. According to them, the cauſe of this *filtration* is, doubtleſs, the ſame with that whereby fluids aſcend up heaps of aſhes, ſand, &c. the ſame with that whereby water is raiſed in form of vapour, the ſap riſes in vegetables, and the blood circulates through the capillary arteries, and the extremely minute glandular ſtrainers. See ASCENT *of fluids*.

FILTRUM, in *Natural Hiſtory*, the name of a ſtone much in uſe in the eaſtern parts of the world, and ſometimes with us for the filtrating of water intended for drinking. The Japoneſe are extremely fond of this ſtone, and impute their uninterrupted health, and particularly, their being always free from the ſtone and gravel to their drinking the water thus cleared of all its heterogeneous and miſchievous particles. The people of this, and many other places thereabouts, have a fettled opinion, that moſt diſeaſes ariſe from impurities of water, and are well aſſured, that theſe impurities are all lodged in the ſtone-filtre, and left behind by the water in its paſſage.

The manner of uſing the ſtone is this; they form a ſort of mortars with very thick bottoms out of the largeſt pieces of it, and the water is poured into theſe, and the ſtone being of a very lax and ſpungy texture, it ſoon makes its way through, and is received into a veſſel placed underneath for that purpoſe. It being found, therefore, an eaſy thing for us to have our water filtered in the ſame manner that the Japoneſe have, it remains to try whether it will have all thoſe ſalutary effects which the people of that part of the world give it; and this ſeems not to be imagined from reaſon and analogy. We very well know that water is frequently impregnated with ſaline particles, and that it alſo frequently diſſolves by this means earthy and other matters which it otherwiſe could not do. But we alſo know, that ſalts diſſolved in water are not to be ſeparated by *filtration*; and it is equally certain, that earthy, ſparry, or other matter, that is ſuſpended in water when *clear*, will in like manner paſs through the filter with it.

Upon the whole, we are happy enough to have no occaſion for filtering ſtones, ſince our ſprings and rivers afford us water already pure enough to our hands; and in places where this is not the caſe, it is always poſſible to have rain-water, which will keep a long time with proper management, and is much purer than all the art in the world can make ſuch as has once been foul. Valentini Muſeum Muſeorum, lib. I. cap. 22.

The only inſtance in which a filtering-ſtone can be of real uſe, is, when there is no water to be had but that of ſome muddy river; in this caſe, the mud being a foreign body not diſſolved in, but only bearing among the water, it will be left behind in its paſſing the cloſe ſtructure in the ſtone; but this is always to be as well obtained by letting it ſtand a while to ſubſide. Ephem. Germ. Cent. iii. p. 76.

FILUM *Aquæ*, the thread or middle of the ſtream where a river parts two lordſhips: *Et hab. hor. ſtat. butter, ſique ad filum aquæ prædictæ. Filum mari, the high ſide of the ſea.* Rot. Parl. 11 Hen. IV.

FIMBRIÆ, *Fringes*. The extremities or borders of the tube Falloppiana were formerly thus called, the word ſignifying a *fringed border*, which that part reſembles. See *Tab. Anat.* (*Splanch.*) *fig.* 9. *lit. d d.*

FIMBRIATED, a term in *Heraldry*, ſignifying that an ordinary is edged round with another of a different colour.

Thus, he beareth, or, a croſs-pattee gules, *fimbriated* ſable.

FIN, *Pinna*, in *Natural Hiſtory*, the name of that part of a fiſh, which diſtinguiſhes it from other aquatic creatures, no animal but a fiſh having *fins* and wanting legs.

The *fin* is properly a part ſtanding out or hanging from the body of the fiſh, and conſiſting of a membrane ſupported by ſeveral rays or oblong bones, which are in ſome hard and firm, and in others cartilaginous.

This definition of a *fin* properly excludes all thoſe other parts of a fiſh which may be prominent from the body, and may be of a membranaceous ſtructure, and even bear the appearance of a *fin*, though they have none of the rays or little bony ſubſtances within them, and therefore cannot ſerve the creature in the office of a *fin* in ſwimming; for the cartilages or bones which ſupport the membranes of the *fins* are what give them their uſe and neceſſary ſtrength and firmneſs to bear againſt the water for the motion of the body of the fiſh; thoſe other membranaceous appendages to the bodies of fiſhes cannot do this; for wanting the ſupport of theſe rays, the ſimple and ſoft membrane has no more power of moving the water than the water has of moving it. Hence appears the uſe of the bones or rays ſupporting the *fins*, and the truth of the definition, that nothing is properly a *fin* which wants them.

The *fins*, by their differences, make very obvious diſtinctions among the ſeveral ſpecies of fiſh; and theſe differences are in regard to number, ſituation, figure, and proportion.

The number of the *fins*, including the tail, is very different in different fiſh. 1. In ſome there is only one *fin* to the whole fiſh: this is the caſe in the ophidium lumbriciforme, and in the murena. 2. The *fins* are two in number in others, as in the petromyzon, and the like. 3. There are many which have three *fins*, as the conger, the eel, the common ophidium, the Greenland whale, the ſea-cow, and the like. 4. Many have four *fins*; of the number of which are the dolphin, the phocæna, and the ſecond kind of the acus Ariſtotelis. 5. Several have five *fins*, as the ammodytes or ſand-eel, the ſword-fiſh, the lupus marinus, the mola or ſun-fiſh, and many others. 6. The lumpeſuh gives us an inſtance of ſix *fins*; for the ſeeming fifth *fin* on the back of that fiſh is not a real *fin*, but only a curious prominence. 7. Many fiſh have ſeven *fins*, as the gurgeon, the pleuronectes, the cyprinus, the clupea, the coregonus, the ſtomeri, the ſalmones, the cobites, the cloces, the cernua fluviatilis, the gaſteroſteus, the ſparus, the labi, the ſiu-

rus, the mugil alatus, the remora, the capriscus, the hippurus, the pompilus, and the acipenser. 8. Many fish also have eight *fins* each; of this number are some of the pearches, the clarea, the cottus, the mugil, the labrax, the sudis, the mullus, the ling, the trachurus, the scyrena, the trachinus, the uranoscope, and that little fish called the anguilla by the Venetians. 9. The scorpæna of Rondeletius gives us an instance of the *fins* being nine in number; and finally, the scombri and thynni give us instances of eleven *fins* in the same fish.

The differences in situation are less numerous than these as to number, but they are not less obvious and essential. 1. They are generally placed both on the back and belly, as we see in most of the species of fishes. 2. They are sometimes placed only on the back; this is the case in the petromyzon, the acus lumbriciformis, and some others. 3. Some have them, on the contrary, only on the belly: of this kind are the Greenland whale, the scolopax, and the like: and to this it is to be added, that the back and belly *fins* differ greatly in the several fish, in their being placed more or less backward or forward.

The differences of shape or figure in the *fins* of fishes are also very obvious. 1. They are in some nearly triangular, as in the cyprini, and salmons, &c. 2. Some few fish have them round. And 3. Some have them of an oblong square or parallelogram figure.

Finally, the difference in proportion is not to be omitted, for they are in some much shorter and smaller than the body, as is the case in the generality of fish; but in others they are of an equal length with the body. Of this kind are the pectoral *fins* in some of the lepri, and the ventral *fins* in the mugil alatus of Rondeletius and other authors. Artedi, Ichthyol. p. 4.

FIN-*fish*, the *balæna physalus* of Linnæus, is a species of WHALE, distinguished from the common whale by a *fin* on the back, placed very low and near the tail.

The office of the *fins* has commonly been supposed to be analogous to that of feathers in fowls, and to aid the fish in its progressive motion or swimming; but the latter naturalists find this a mistake.

It is the tail that is the greatest instrument of swimming; the *fins* only serve to keep the fish upright, and prevent vacillation or wavering. See SWIMMING *of fish*.

FINS, *whale*, are commonly taken for that part of the whale which the populace call WHALE-*bone*; but whence the mistake should arise is not easy to determine.

These *whale-fins*, as some have erroneously called them, are the most valuable part of the animal. See *Whale* FISHERY and WHALE-*bone*.

FINAL, that which terminates or comes last in any thing, as a *final* judgment, *final* sentence, &c.

FINAL *cause*, is the end for which the thing is done. The *final cause* is the first thing in the intention of a person who does a thing; and the last, in the execution. See CAUSE.

FINAL *letters* are those which close words.

The Hebrews have five *final* letters, which, when at the end of a word have a different figure from what they have at the beginning or in the middle thereof. These are the ך ם ן ף ץ *caph, mem, nun, pe, tsaar*, which every where but at the end of words, are wrote כ מ נ פ צ.

FINANCES, in the *French Policy*, denote the revenues of the king and state; much the same with the treasury or exchequer of the English, and the fiscus of the Romans. The word is derived from the German, *finantz, scraping, misery*; though Du-Cange chooses rather to deduce it from the barbarous Latin, *finantia, præstatio pecuniaria*.

FINANCES, *council of the*, corresponds to our lords commissioners of the treasury, the comptroller general of the *finances*, to our lord high treasurer, &c.

The French have a peculiar kind of figures or numeral characters, which they call *chiffre de finance*. See CHARACTER.

FINANCES, *British*. See FUND.

FINCH, in *Ornithology*. See FRINGILLA.

FINDERS, in our *Old Statutes*, are supposed to be the same with those we now call searchers, who are employed for the discovery of goods imported or exported without paying custom. Stat. 18 Ed. III. 14 Ric. II. 17 Ric. II. &c.

FINDER, among *Sportsmen*. See *Water*-DOG.

FINDING *of a bill of indictment in Law*. See INDICTMENT.

FINE, that which is pure, and without mixture. The term is particularly used in speaking of gold or silver. See GOLD and SILVER.

FINE, in *Law*, denotes a covenant made before justices, and entered of record, for conveyance of lands, tenements, or any thing inheritable, being *ab esse ad non esse*, in order to cut off all future controversies.

A *fine*, then, appears to be a concord, acknowledged and recorded before a competent judge, touching some hereditament or thing immoveable that was in controversy between the parties to the same concord; and for the better credit of the transaction, it is supposed to be made in the presence of the king, because levied in his court.

Hence it binds women covert, being parties, and others whom ordinarily the law disables to transact, only for this reason, that all presumption of deceit or evil-meaning is excluded where the king and his court of justice are supposed to be privy to the act.

Originally this *final* concord was instituted and allowed, in regard that by the law and ancient course of proceedings, no plaintiff could agree or end the cause without licence of the court; to that *fines* have been anciently levied in personal actions, and for no greater a sum of money than 13*l*.

But time has produced other uses of *fines*, viz. to cut off entails, bar dowers, and with more certainty to pass the interest or title of any land or tenement, though not controverted, to whom we think good, either for years or in fee; insomuch, that the pulling a fine in most cases now is but a *fiducia iuris*, supposing an action or controversy, where, in truth, none is, until to our only operating to a perfect bar and conclusion against the conusor or person who passes the *fine*, and his heirs; but at five years end, against all others, not expressly excepted, and not claiming (if it be levied upon good consideration, and without covin); as women covert, persons under twenty-one years, prisoners, or such as are out of the realm at the time of its acknowleging; and persons *non sanæ memoriæ*, who are allowed the same time after their malady is removed.

To this purpose a *fine* after the engrossing must be openly read and proclaimed in the court of common pleas, once in the term when they were engrossed, and once in each of the three succeeding terms, and a transcript of it sent to the justices of assize, and another to the justices of the peace of the county where the land lies, to be proclaimed there. The day and year of acknowleging a *fine* and warrant of attorney for suffering a recovery are to be certified with the concord; and an office hath been appointed for the inrollment of writs for *fines*; and the chirographer, on the fifth day of every term, is to fix in the court of C. B. or common pleas, a table containing the *fines* passed in the term before in every county, by stat. Eliz. cap. 3.

Every *fine* hath in it five essential parts: 1. An original writ, usually a writ of covenant. 2. The king's licence, giving the parties liberty to accord; for which he hath a *fine* called the *king's silver*, being accounted part of the crown revenue. 3. The concord itself, which begins thus, *Hæc est conventio talis*, &c. 4. The note or abstract of the *fine*, beginning thus, K. *tuor* R. *quorentem*, & S. & T. *tenentem ejus deforciantes*, &c. (where instead of *deforcientes*, anciently *impedientes* was used.) 5. The foot of the *fine* (*Hæc est finalis concordia facta in curia domini regis apud Westm. a die Paschæ in quindecim dies, anno*, &c.) concludes all, containing the day, year, and place, and before what justice the concord was made.

Fines are either with proclamations, called *fines* according to the statutes, which are the best sort, and most used; or without proclamation, called *fines* at the common law.

Fines are either *single* or *double*.

FINE, *single*, is that by which nothing is granted or rendered back again by the cognisees to the cognisors, or any of them.

FINE, *double*, contains a grant and render back, either of some rent, common, or other thing out of the land, or of the land itself, to all or some of the cognisors for some estate, limiting thereby remainders to strangers not named in the writ of covenant.

In this kind of *fine* called *sur* DONE, grant and render, both the *fines sur cognizance*, &c. and *sur concessit*, are formed into one, and it is partly executed and partly executory.

Sometimes also a *double fine* is when the lands lie in several counties.

Fines, with regard to their effect, are divided into *executed* and *executory*.

FINE *executed*, is such as of its own force gives a present possession (at least in law) to a cognisee; so that he needs no writ of *habere facias seisinam* for execution of the same; of which sort is a *fine sur cognizance de droit come ceo*, &c. that is, upon acknowlegment, that the thing mentioned in the concord is *jus ipsius cognitoris, ut ille quæ tenet habet de dono cognitoris*. Well. § 51. K.

The reason is, because the *fine* passeth by way of release of a thing which the cognisee hath already (at least by supposition) by virtue of a former gift to the cognisor, which is, in truth, the surest *fine* of all.

FINES *executory*, are such as of their own force do not exe-

cute

cute or give the poſſeſſion to the coniſee without entry or action, but require a writ of *habere facias ſeiſinam*; as a *fine for cognizance de droit tantum*, unleſs the party be in poſſeſſion of the lands. This kind of *fine* is commonly made uſe of to paſs a reverſion. There is alſo another executory *fine*, called *ſur conceſſit*, which is uſed to grant away eſtate for life or years, when the coniſor is ſeiſed of the lands contained therein, and the coniſor hath no freehold in it, but remains poſſeſſed by the *fine*.

Fines in England are now levied in the court of common pleas at Weſtminſter, in regard to the ſolemnity thereof, ordained by the ſtatute of 18 Ed. I. ſtat. 4. before which time they were ſometimes levied in the county-court, court barons, and in the exchequer, as may be ſeen in Origines Juridiciales, &c.

Fines are alſo taken by commiſſioners in the country, impowered by *dedimus poteſtatem*. 15 Ed. II. ſtat. *de fin.* Though by the common law all *fines* were levied in the court. *Fines* levied before the Juſtices in Wales, or in the counties palatinate of Cheſter, Durham, &c. have the ſame effect as thoſe that are levied before the juſtices of C. B. Plowden ſays, that there were *fines* levied before the Conqueſt: Fulbeck aſſures us alſo, that he has ſeen the exemplification of one of Henry the Firſt's time; though Dugdale affirms, there were none till Henry the Second.

FINE *adnullando levato de tenemento quod fuit de antiquo dominico*, a writ directed to the juſtices of C. B. for diſannulling a *fine* levied of lands in ancient demeſne to the prejudice of the lord. Reg. Orig. 15.

FINES *for alienation*, are reaſonable *fines* formerly paid to the king by his tenants in chief, for licence to alienate their lands; according to the ſtatute 1 Edw. III. cap. 12. but taken away by ſtatute 12 Car. II. cap. 24.

FINE *capiendo pro terris*, &c. a writ lying where a perſon upon conviction of any offence by jury hath his land and goods taken into the king's hands, and his body is committed to priſon, to be remitted his impriſonment, and have his lands and goods re-delivered him on obtaining favour for a ſum of money. Reg. Orig. 142.

FINE, *force*, is an expreſſion in ſtat. 35 Hen. VIII. cap. 12. denoting that a perſon is *forced* to do that which he can in no way avoid.

FINE *levando de tenementis tentis de rege in capite*, &c. a writ directed to the juſtices of the common pleas to admit of a *fine* for the ſale of land holden of the king *in capite*. Reg. Orig. 167.

FINE *non capiendo pro pulchre placitando*, a writ to inhibit officers of courts to take *fines* for fair pleading. Reg. Orig. 179.

FINE *pro redditione capiendo*, &c. a writ lying for the releaſe of one impriſoned for a redditeſſim, on payment of a reaſonable fine. Reg. Orig. 222.

FINES *le roy*, in *Law*, are all *fines* to the king. Under this head are included *fines* for original writs. Thus, for every writ of plea of land, if it be not of right patent, which is for the yearly rent of five marks; and for all original writs in debt and treſpaſs, where the debt or damage is 40*l.* a *fine* is due to the king of 6*s.* 8*d.* and more proportionably when the writ is for greater value.

FINE alſo, according to Cowel, ſignifies a ſum of money paid as an income for lands or tenements let by leaſe, anciently called *groſſuma*.

FINE is alſo uſed to denote an amends, pecuniary puniſhment, or recompence, for an offence committed againſt the king and his laws, or againſt the lord of a manor.

In which caſe a man is ſaid, *facere finem de tranſgreſſione cum rege*, &c.

In all the diverſities of the uſe of the word *fine*, it hath but one ſignification; and that is, a *final* concluſion, or end of differences between parties. In the laſt ſenſe, where it denotes the ending and remiſſion of an offence. it is uſed by Bracton, who ſpeaks of a *common fine* that the country pays to the king for falſe judgments or other treſpaſſes, which is to be aſſeſſed by the juſtices in eyre before their departure, by the oaths of knights and other good men, upon ſuch as ought to pay it.

There is alſo a *common fine* in courts leet.

FINE-*drawing*, or *reutering*, a very nice way of ſewing up or rejoining the parts of any cloth, ſtuff, or the like, torn or rent in the dreſſing, wearing, &c.

It is prohibited to *fine-draw* pieces of foreign manufacture upon thoſe of our own, as has formerly been practiſed. See RENTERING.

FINE-*ſtiller*, in the *Diſtillery*. That branch of the art which is employed on the diſtilling the ſpirit from treacle or other preparations or recruments of ſugar, is called *fine-ſtilling*, by way of diſtinction from malt-ſtilling; and the perſon who exerciſes this part of the trade is called a *fine-ſtiller*.

The operation in procuring the ſpirit from ſugar is the ſame with that uſed in making the malt ſpirit; a wath of the ſaccharine matter being made with water from treacle, &c. and fermented with yeaſt. It is uſual to add in this caſe, however, a conſiderable portion of malt, and ſometimes powdered jalap, to the fermenting backs. The malt accelerates the fermentation, and makes the ſpirit come out the cheaper, and the jalap prevents the riſe of any muſty head on the ſurface of the fermenting liquor, ſo as to leave a greater opportunity for the free acceſs of the air, and thus to ſhorten the work, by turning the ſoamy into a hiſſing fermentation. Shaw's Lect. p. 280.

FINERS *of gold and ſilver*, are thoſe who purify and part thoſe metals from other coarſer ones by fire and acids.

They are alſo called *parters*, in our old law-books, and ſometimes *departers*.

FINERY, in the *Iron-works*, is one of the two forges at which they hammer the ſow or pig iron.

Into the *finery* they firſt put the pigs of iron, placing three or four of them together behind the fire, with a little of one end thruſt into it; where, ſoftening by degrees, they ſtir and work them with long bars of iron, and expoſe at different times different parts to the blaſt of the bellows, in order to refine it as equally as poſſible, till the metal runs together with a round maſs or lump, which they call a *half-bloom*. They then take this out, and give it a few ſtrokes with their ſledges; afterwards they carry it to a great heavy hammer, raiſed by the motion of a water-wheel: where, applying it dexterouſly to the blows, they preſently beat it out into a thick ſhort ſquare. This they put into the *finery* again, and heating it red-hot, they work it out under the ſame hammer till it comes to be in the ſhape of a bar in the middle, but with two ſquare knobs at the ends, which they call an ANCONY. It is then carried into the other forge, called the CHAFERY. Phil. Tranſ. N° 137, or Abr. vol. ii. p. 559.

FINEERING. See VENEERING.

FINESSE, a French term, of late current in Engliſh. Literally, it is of no farther import than our Engliſh *fineneſs*; but among us it is chiefly uſed to denote that peculiar delicacy or ſubtlety perceived in works of the mind, and the neceſſ and moſt ſecret and ſublime parts of any ſcience or art.

It is ſometimes uſed to expreſs that kind of ſubtlety made uſe of for the purpoſes of deception.

FINGERS, *Digiti*, the extreme part of the HAND, divided into five members.

The *fingers* conſiſt of fifteen bones, diſpoſed in three rows or ranks, each *finger* having three bones.

The joints or jointures are called *condyli* and *internodia*; and their arrangement or rows, *phalanges*; the uppermoſt of which is the longeſt and largeſt; the ſecond leſs, but yet longer and larger than the third.

The firſt *finger* is called the *pollex* or the THUMB; the ſecond, *index*, ſometimes *ſalutarius* *digitus*, and ſometimes *numerarius*; the third, the middle *finger*, *infamis*, *obſcenus*, *impudicus*, and *fanaticus*, becauſe uſed in mocking and deriſion; the fourth, *annularis*, the ring *finger*, *medius pronubus* and *medicus*, becauſe the ancients uſed to ſtir and mix their medicines therewith; the fifth, the little *finger*, *auricularis*, becauſe the ear is picked therewith.

FINGERS, *bones of the*. The phalanges of the bones of the *four fingers* are all of nearly the ſame ſtructure, differing only in ſize. The firſt phalanges are made nearly in the ſame manner with the ſecond of the thumb, only that they are lower on their concave ſides, and more rounded at their convex ſides. They are alſo larger in proportion and the edges of the flat ſides have the ſame rough line as the ſecond phalanx of the thumb. Their baſes are more hollow for their articulations with the metacarpal bones, and their heads are formed like pullies. The ſecond phalanges are ſhorter, narrower, and thinner than the firſt; both phalanges are gently incurvated, and reſemble each other in ſtructure, except that the ſecond contract by degrees from their baſes to the heads, which are very ſmall, and that their bones have a double cavity for their articulation by ginglymus, with the heads of the firſt phalanges. Their flat ſides have all the before mentioned rough lines. The third phalanges are in every thing like that of the thumb (which ſee) but that they are ſmaller, each of them being proportioned to the *fingers* they belong to. It is to be obſerved of all the phalanges, that their baſes have ſmall tuberoſities; and their heads, except thoſe of the laſt phalanges, have on each ſide a ſort of roundiſh foſſula, bordered with ſmall eminences. Winſlow's Anatomy, p. 88.

Mr. Houſtoun has given us obſervations on the ſtructure and action of ſome MUSCLES of the *fingers* in the Mem. Acad. Sciences for 1720.

FINGERS, *ſuperfluous*. Infants are often born with ſuper-

fluous or super-numerary *fingers*, which are usually misshapen and misplaced; some of these are found to have nails and bones like the other fingers; others have none of these, but are mere mafles of fleth.

These fhould always be amputated in the infancy of the child; but if they are many in number, and the child but weakly, it may be better not to take them all off at one time, but to ftay fome time between each amputation, that one may be almoft well before another is taken off. They are to be cut off with the fcalpel or fciffars, and the hæmorrhage ftopped with dry lint or with the fame dipped in fpirit of wine, and afterwards healed as common wounds with vulnerary balfams. Heifter's Surgery, p. 330.

FINGERS, *carious*. The *fingers* when carious, or affected by a fphacelus ventofa, are to be amputated three ways. 1. By a pair of ftrong fciffars or fharp-edged pinchers. 2. By a chiffel ftruck by a leaden mallet, by which they are feparated at one blow; or laftly, by dividing the next found joint with a fcalpel, and drawing back a part of the fkin to wrap over the ftump that it may heal the fooner; and this is the beft method of all, as by this you are in no fear about any fplinters of the bone being left. Heifter's Surgery, p. 331.

FINGERS, *fractured*. When one or more of the bones in the *fingers* are broke, the furgeon's bufinefs is carefully to replace what has been removed, and to roll up the *finger* a little way with a narrow bandage, and then to bind it firmly to the next found *finger*. But it is much more proper, when the *finger* is mafhed fo as to give no hope of a good cure, to take it off at once. Heifter's Surgery, p. 129.

FINGERS, *luxated*. The bones of the *fingers* and thumbs are liable to luxations of each of their articulations, and that in feveral directions; but thefe are accidents, not only eafily difcovered, but very eafily remedied alfo; for the ligaments being not very robuft, the fat and mufcles thin, and the finufes of the articulations fhallow, the extenfion is very eafy, and the reduction of them into their former places not lefs fo. The beft method is to extend fufficiently the *finger* with one hand, and to replace the luxated bone at the fame time with the other, and to retain it by a proper bandage. Heifter's Surgery, p. 166.

FINGER'S *breadth*, a meafure, of two barley-corns in length, or four laid fide to fide.

FINGERY, in *fcheiology*. See BRANLIN.

FINGITES, a name given by fome of the barbarous writers of the middle ages to the phengites, a very tranfparent fort of marble ufed by the Romans in building.

FINGRIGO, *Pifonia*, in *Botany*, a genus of the *polygamia dioecia* clafs. Its characters are thefe: the male flowers grow upon different plants from the fruit. The male flowers are funnel-fhaped, the tube is fhort; the brim is expanded, and cut into five acute parts; they have five awl-fhaped ftamina, which are longer than the petal, terminated by obtufe fummits: the female flowers are of the fame form; they fit upon the germen, which is fituated under the receptacle, fupporting a cylindrical ftyle longer than the petal, crowned by five oblong fpreading ftigmas. The germen afterwards turns to an oval capfule, having five angles and one cell, containing one fmooth, oblong, oval feed.

We have but one fpecies at preſent in England, viz. the prickly pifonia, called *fingrigo* in the Weſt Indies. Theſe plants are very common in the favannas and other low places in the iſland of Jamaica; as alſo in ſeveral other iſlands in the Weſt Indies, where they are very troubleſome to any one who paſſes through the places of their growth, faſtening themſelves by their ſtrong crooked thorns to the cloaths of perſons; and their ſeeds being glutinous and hurry, alſo faſten themſelves to any thing that touches them; ſo that the wings of the ground-doves and other birds are often ſo loaded with the ſeeds as to prevent their flying, by which means they become an eaſy prey. Miller.

FINING. See REFINING.

FINING *of wines*. The uſual method of *fining* down wines, ſo as to render them expeditiouſly bright, clear, and fit for uſe, is this: take an ounce of iſinglaſs, beat it into thin ſhreds with a hammer, and diſſolve it by boiling in a pint of water; this when cold becomes a ſtiff jelly. Whilk up ſome of this jelly into a froth with a little of the wine intended to be fined, then ſtir it well among the reſt in the caſk, and bung it down tight; by this means the wine will become bright in eight or ten days. This method, however, is found to be beſt ſuited to the white wines; for the red ones, the wine coopers commonly uſe the whites of eggs beat up to a froth, and mixed in the ſame manner with their wines. The method by which theſe viſcous bodies act in the operation is this; they entangle themſelves among the flying lee or light faculencies that float in the wine, and thus forming a maſs ſpecifically heavier than the wine, they ſink through the body thereof like a net, carrying down all the foulneſs they meet in the way to the bottom; but when the wine is extremely rich, ſo that its ſpecific gravity is greater than that of the maſs formed by the ingredients uſed in *fining* and the dregs or lee; this maſs then riſes upward, and floats at the ſurface of the wine, which will in this caſe alſo draw off fine. See CLARIFICATION and FORCING.

FINIRE, in *Law*, was uſed to fine, or pay a fine upon compoſition and making ſatisfaction. It is the ſame with *finem facere*, mentioned in Leg. Hen. I. cap. 53.

FINISHING, in *Architecture*, &c. is frequently applied to the CROWNING of ACROTERIA over a piece of building, placed there to terminate and finiſh it.

FINITE, ſomething bounded or limited, in contradiſtinction to infinite.

The ſchoolmen make two kinds of *finite*.

The one as to *extenſion*, which is applied to things that have not all poſſible or conceivable extenſion.

The other as to *perfection*, applied to things which have not the laſt perfection.

To get an idea of a thing *finite* in point of perfection, we firſt conceive the thing as having certain perfections; and then conceive ſome other perfection which it has not, or ſome perfection in a farther degree.

After the ſame manner I conceive a room to be *finite*, by having an idea of extenſion beyond what is contained therein.

FINITO, in the *Italian Muſic*. A CANON or FUGUE is ſaid to be *finito* when it is not perpetual; but when at ſome certain places all the parts join or unite, after having followed one another for ſome time.

FINITOR, in *Aſtronomy*, the HORIZON; thus called, becauſe it finiſhes or bounds the ſight or proſpect.

FINNIKIN, the name of a particular ſpecies of pigeon, called by Moore the *Columba in tyrum ſtellens*. It is of the ſhape and ſize of the common pigeon. The crown of its head has ſomething of the reſemblance of a ſnake's head; and it is gravel-eyed, and has a tuft of feathers on the hinder part of its crown, which runs down its neck not unlike a horſe's mane. It is not feather-legged, and is in colour always either a black or blue pied.

They have their name from their ſingular manner of courting the female, which it always by riſing over her, and making three or four turns, flapping the wings, and then turning as many times round the other way.

FINOCHIA, in *Gardening*, the name of a plant which has of late years been introduced into the Engliſh gardens, and cultivated as a ſallad herb. See FENNEL.

The culture of it is this: good ſeeds muſt be firſt procured from Italy, for thoſe of Engliſh ripening are very apt to degenerate. In March ſome of theſe ſhould be ſowed for the firſt crop on a light rich earth, and in a warm ſituation. The manner of ſowing theſe ſeeds is firſt to take the bed very ſmooth, then draw a ſmall rill along it, and in this ſcatter them pretty thin, for the plants are not to ſtand nearer than ſix inches to one another; cover this with half an inch of earth, and at the diſtance of eighteen inches make another rill, and ſo on throughout the bed. In about a month the plants will come up, and they muſt be then cleared of weeds, and cut up to four inches diſtance; a month after this they muſt be thinned to ſix or ſeven inches diſtance; the ſtalks will now begin to ſwell to a large bulk juſt above the ground, this part muſt be earthed up in the manner of celery about a fortnight before it is uſed, which will make it eat very tender and criſp.

A ſecond crop ſhould be ſown three weeks after the firſt; and in that manner till July: every three weeks or month a new crop ſhould be ſown, to keep a conſtant ſupply for the table. The crops ſown in the hotter weather ſhould be watered and ſhaded from the great heats. *Miller*.

FINSCALE, an Engliſh name for the river fiſh, more uſually called the RUDD, the *rutilus lacus*, or *rubellio fluviatilis* of authors.

FINTO, in the *Italian Muſic*, ſignifies a feint, or an attempt to do ſomething, and not to do it; as *cadenza finta*, is when having done every thing proper for a true cadence, inſtead of falling on the right final, another note, either higher or lower, is taken, or perhaps a pauſe brought in.

FIOL, or FIAL. See PHIAL.

FIR-*tree*, *Abies*, in *Botany*, a genus of the *monoecia monadelphia* claſs. To this genus Linnæus refers the pine and larch trees, making them as well as the *fir-trees* only different ſpecies of the PINUS. Its characters are theſe: there are male and female flowers on the ſame tree; the male flowers are produced at remote diſtances from the cones on the ſame tree; they are compoſed of many ſtamina ſupporting great ſummits, and diſpoſed in a conical ſpike. The female flowers are collected in a ſcaly cone,

each ſcale covering two flowers, having no petals; but from the embryo there ariſes a ſingle ſtyle, covered with a blunt ſtigma; which embryo afterwards turns to an oblong ſeed or nut, incloſed between the pales of the cone, each ſcale having commonly two ſeeds under it. The diſtinguiſhing character of this genus is, that the leaves ariſe ſingly from their baſe, whereas the pines have two or more riſing from the ſame point. There are nine ſpecies now in the Engliſh gardens. The moſt common are the ſilver or yew-leaved *fir-tree* and the pitch-tree, or the Norway or ſpruce *fir*. The firſt grows in great plenty about Straſburgh and other parts of Germany, from whence the turpentine is brought to England; but the moſt beautiful of theſe trees grow on mount Olympus. The ſecond ſort is common in the woods of Norway, and affords the white deals. Of this tree there are two or three varieties; from this the pitch is drawn, whence its name. There are two ſpecies natives of America, one called the black ſpruce *fir*, and the other the white ſpruce *fir*, becauſe the leaves of both are uſed indifferently for making of SPRUCE-*beer*. Theſe two ſpecies alſo yield a fine clear ſtrong-ſcented turpentine, which the native Indians uſe to cure green wounds, and for ſome internal diſorders. The phyſicians of North America have lately adopted it into their practice. There is another ſpecies the native of America, called the balm of Gilead *fir*, becauſe it affords a clear fragrant turpentine, commonly ſold in England for the balm of Gilead.

The manner of propagating *fir*, pines, and other trees of that kind from ſeeds is this: the ripe cones of theſe trees are to be either expoſed to a gentle heat, or ſoaked for twelve hours in warm water; after which the ſeveral cells will open, and the ſeeds fall out.

Theſe ſeeds ſhould never be taken out till the time of ſowing them, which is the latter end of March. The ground they are to be ſown in muſt be carefully turned ſeveral times, to deſtroy the roots of weeds. For a large plantation, this is beſt done by ploughing ſeveral times; after this, the earth is to be levelled with a ſpade in ſmall ſpots at every ſix feet ſquare; in each of which ſpots ten or twelve ſeeds are to be ſown, and covered with ſome of the ſame mould broken fine, but not ſifted; then they are to be covered with a furze buſh or other ſuch covering; and this is to remain for ſome time after the plants are come up, but they muſt not be covered too cloſe by it; when this covering is taken off, a little looſe earth is to be drawn about the ſtems of the plants, and a little furze ſtuck about them, to keep off the too great heat of the ſun. Uſually from twelve ſeeds there are eight plants or thereabouts, and theſe may be left ſtanding together till the third year. In March or April, the third year after ſowing, the plants are to be removed to the place where they are to ſtand, and planted at eight foot ſquare diſtance, or greater, if deſired. Two plants ſhould, however, be left in the plantation in each cluſter, and great care taken not to injure the roots of theſe. The others alſo muſt be taken up with as much earth about their roots as poſſible. When they are ſet in the new plantation, there muſt be ſtakes fixt near them to tie them to, that the wind may not blow them down, and the roots muſt be covered with litter, and they muſt have a gentle watering to ſettle the earth to their roots. If the weather prove very dry, this may be repeated two or three times, but a little at a time; over-watering kills all new-ſet trees; and the cutting away of the heads or branches of thoſe of the reſinous kind is a very dangerous thing.

The Scotch pine delights in a chalky ſoil on the ſide of a hill, but will alſo grow in gravel, and in any ground that is not too wet.

The common *fir* loves a loamy ſtrong ſoil, and is a native of low flat grounds; and moſt of the American *firs* and pines love a looſe moiſt ſoil. The ſilver *fir*, and the manured pine, love a dry ſituation, but muſt have a deeper ſoil than the Scotch pine, and muſt be ſheltered from the north winds. The two trees left in each ſpot of the place where they were ſown may be left together ſeven years, then the leaſt flouriſhing tree is to be carefully removed. Miller.

FIR, *muſk upright*. See LYCOPODIUM.

FIR, *Scotch*, in *Botany*. See PINE.

FIRDFARE. See FERDFARE.

FIRDWITE. See FIRD-WIT.

FIRE, in *Phyſiology*. The moſt univerſal and ſenſible character of *fire*, and that which beſt defines and diſtinguiſhes it from every other thing, is, its giving *heat*.

Fire, therefore, may be generally defined to be whatever warms or heats bodies.

Again, as heat is ſomething whoſe preſence we beſt perceive by the dilatation of the air, ſpirit, or mercury in the thermometer; *fire* may be defined to be that whoſe preſence we perceive by the expanſion of theſe in the thermometer.

Whence it follows, that *fire* is an elaſtic body, compoſed of infinitely ſmall particles, fcarcely if at all adhering to each other, and a body in motion. Its motion is argued from its expanding the air, which is not effected without communicating motion thereto; and its corporeity is proved by experiment. For pure mercury being incloſed in a phial with a long neck, and kept in a gentle heat for the ſpace of a year, is reduced into a ſolid; and its weight is conſiderably increaſed; which increaſe, ſome have ſuppoſed, can ariſe from nothing but the acceſſion of *fire*. See the ſequel of this article, and CALCINATION.

Its ſolidity is alſo evinced by its reflection from burning-glaſſes; the ſmallneſs of its conſtituent particles by the facility with which it penetrates any body however denſe, or ſeparates itſelf from any ſuch body.

Fire makes one of the vulgar or Peripatetic elements, defined to be hot and dry; or it is that part or ingredient in all bodies which is hot in the higheſt degree, and dry in an inferior one.

What the ſchool-philoſophers add farther as to the nature of *fire* is, that it is a ſimple body, as not including any contrariety of qualities; and a body abſolutely light, as tending naturally upward; for which reaſon they hold its natural place to be above all the other elements, between the extremity of our atmoſphere and the moon; and the ſame of *fire* is ſuppoſed to reſide in that ſphere, which they call *elementary fire*.

Fire, according to the Carteſians, is an aſſemblage of the more ſolid, earthy particles, which, ſwimming in the rapidly fluid matter of the firſt element, become vehemently agitated thereby; and by this intenſe agitation or motion are diſpoſed to give the ſenſation of heat, light, &c.

Fire, according to Sir Iſaac Newton, is a body heated ſo hot as to emit light copiouſly; for what elſe, ſays that philoſopher, is red hot iron, but *fire*? And what elſe is a *fiery* coal than red-hot wood? By which he ſuggeſts, that bodies which are not *fire* may be changed and converted into *fire*.

It is a diſpute of ſome ſtanding among philoſophers, whether *fire* be any ſpecific ſubſtance, originally diſtinct from all other; or whether it be of the common matter of other bodies, only under certain peculiar modifications; i. e. whether *fire* be ſuch by its own nature, or by motion? See HEAT, under which article the reader will find this controverſy more largely ſtated and explained. See alſo *Theory of* ELECTRICITY and PHLOGISTON.

According to ſome of the lateſt philoſophers, *fire* is a certain ſubſtance or body, *ſui generis*, originally ſuch, and not producible by any motion or alteration of other bodies.

Theſe authors deſcribe *fire* as a very ſubtle, moveable, penetrating body, the cauſe or inſtrument of HEAT and LIGHT.

Some of them add, that when *fire* enters the eye in right lines it produces or excites the idea of light, which rectilinear motion they account abſolutely neceſſary to the idea of light.

Whereas, to produce heat, and the other effects of *fire*, ſuch rectilinear motion is not required; but on the contrary, an irregular, various motion is fitter to produce the ſame.

Others diſlike the uſe of the term *fire* as a conſtituent principle of natural bodies, becauſe in the general application of it heat has alſo been included; and therefore the term has become ambiguous, and it is neceſſary to diſtinguiſh continually between *fire* in a ſtate of action and inactive or quieſcent *fire*. They have therefore preferred the term PHLOGISTON for denoting one and the ſame unknown cauſe of certain well known effects. Prieſtley's *Exp. and Obſ. &c.* vol. i. p. 282, *&c.*

The nature of *fire* is ſo wonderful and abſtruſe, that the ancients generally revered it as a god: among the moderns we can ſcarce name one point in all philoſophy of more importance, or one that is leſs underſtood.

Fire, in effect, is the univerſal inſtrument of all the motion and action in the univerſe; without *fire* all bodies would become immoveable; as in a ſevere winter we actually ſee our fluids become ſolid for want thereof. Without *fire* a man would harden into a ſtatue, and the very air would cohere into a rigid maſs.

Fire, then, is the univerſal cauſe of all mutation or change; for all mutation is by motion, and all motion by *fire*.

Several authors have laboured to ſet this grand agent in its juſt light; and particularly the excellent Boerhaave, in a new courſe of experiments and lectures expreſſly on the ſubject, *De Igne*. The ſum of his doctrine we ſhall here ſubjoin:

Fire, then, is diſtinguiſhed into two kinds; as it is in itſelf

itself called *elementary fire*; and as it is joined with other bodies, called *culinary fire*.

FIRE, *pure* or *elementary*, is such as exists in itself, which alone we properly call *fire*, and has lately been denominated absolute HEAT.

FIRE, *common* or *culinary*, is that existing in ignited bodies, or excited by the former in combustible matters, the minute particles whereof joining with those of the pure *fire* constitute pure flame.

This latter is improperly called *fire*, in regard only a small part of it is real or pure *fire*.

Pure *fire* is such as collected in a burning-glass yields no flame, smoke, ashes, or the like; consequently, in ignited bodies, that which flames, smokes, &c. is not simply *fire*.

The effects, nature, properties, &c. of each shall be considered: 1. *Pure* or *elementary fire* of itself is imperceptible, and only discovers itself by certain effects which it produces in bodies, which effects are only learnt by observing the changes that arise in those bodies.

The first effect of *elementary fire* on bodies is heat, which arises wholly from *fire*; and in such manner as that the measure of heat is always the measure of *fire*, and that of *fire* of heat. So the heat is inseparable from *fire*.

The second is dilatation in most solid bodies, and rarefaction in all fluids.

That both these are inseparable from heat, is evident from numerous experiments. An iron-rod or bar being heated, increases in all its dimensions: and the more so as it is further and further heated: upon exposing it to the cold again, it contracts, and returns successively through all the degrees of its dilatation till it arrives at its first bulk, being never two minutes successively of the same magnitude. See HEAT and PYROMETER.

The like is observed in the heaviest of all bodies, gold, which, when fused, takes up more space than before; so mercury, the heaviest of all fluids, we have known to ascend in a narrow tube over the *fire* to above thirty times its height.

The laws of this expansion are, 1. That the same degree of *fire* rarefies fluids fewer, and in a greater degree than it does solids. Without this the thermometer would be of no use, since the cavity of the tube would then be dilated in the same proportion as the fluid is rarefied. 2. The lighter the fluid, the more it is dilated by *fire*. Thus air, the lightest of all fluids, expands the most, and next after air, spirit of wine. See THERMOMETER. Some substances are capable of a greater dilatation or diminution of their specific gravity than others by *fire*. Thus, certain matters are so much rarefied by even a moderate heat, that they seem to lose all their specific gravity, or become at least specifically lighter than all the surrounding bodies; hence these substances when heated to a certain degree, are raised as bodies would be without gravity. All substances which have this property are called in general volatile substances. See VOLATILISATION. Other bodies are so little dilatable by *fire* relatively to their density, that the greatest heat which can be given them produces almost an insensible diminution of specific gravity. These, being almost unalterable in this respect by *fire*, are called fixed bodies. See FIXITY.

The third effect of *fire* on bodies is motion; for *fire*, in warming and dilating bodies, must of necessity move their parts.

In effect, all the motion in nature arises from *fire*, alone; and, taking this away, all things become immoveable. Upon the absence of only a certain degree of *fire*, all oils, fats, waters, wines, ale, spirits of wine, vegetables, animals, &c. become hard, rigid, and inert; and the less the degree of *fire*, the sooner and more violently is this induration made.

Hence, if there were the greatest degree of cold, and all *fire* were absolutely taken away, all nature would grow into one concrete body, solid as gold, and hard as a diamond; but upon the application of *fire*, it would recover its former mobility.

Consequently, every diminution of *fire* is attended with a proportionable diminution of motion, and *vice versa*.

This *fire*, whose effects we have been relating, needs no air or pabulum to sustain or preserve it. For putting some calx of tin or lead in the exhausted receiver of an air-pump, and applying a burning-glass, so that the focus shall fall on the calx, the consequence will be a vehement dilatation of the calx from the center towards the circumference, whereby the receiver will be broken into a thousand pieces; and if a quantity of any essential aromatic oil be poured, *in vacuo*, upon spirit of nitre, there will immediately arise a violent *fire*, to the great danger of the by-standers.

All the above mentioned effects of *elementary fire* may be increased divers ways, viz.

1. By attrition, or a swift agitation or rubbing of one body against another. This is apparent in solids; a vehement attrition of a flint and steel, every body knows, will produce sparks. So also in fluids, cream, by long churning, to separate the butter, will grow sensibly warm; the barometer renders this effect still more discernible.

In effect, all the heat of an animal, says Boerhaave, is owing to the agitation and attrition of the parts of its juices against each other, and against the sides of the vessels.

The more solid, hard, and elastic, the bodies thus agitated are, the more points of contact they have; the more intense the force whereby they are struck against each other is, the greater is their motion; and the quicker the returns of their strokes, and the longer they are continued, the greater is the heat produced.

Thus, a piece of sponge rubbed lightly, and for a little while against another, acquires no sensible heat; but a large heavy piece of iron briskly rubbed against another in a cold season (when bodies are the densest) will presently acquire an intense heat sufficient to *fire* sulphur, gunpowder, or the like.

So a knife wetted briskly on a dry rough stone shall yield sparks of *fire*; but if oil, or any other fatty matter be interposed, no sensible heat shall arise; and the points of two needles rubbed against each other ever so strongly, or so long, will never grow warm, as only touching in a few parts. In New Holland they produce *fire* with great facility by means of two pieces of dry soft wood; one of which is a stick about eight or nine inches long, and the other is flat; the stick they shape into an obtuse point at one end, and pressing it upon the other, turn it nimbly by holding it between both their hands as we do a chocolate-mill, often shifting their hands up, and then moving them down upon it, to increase the pressure as much as possible. By this method they get *fire* in less than two minutes. Hawkesworth's Voyages, &c. vol. iii. p. 234. Hence, 1. The globules of the crude or red blood driven by the force of the heart against each other, or against the sides of the arteries, excite more heat than the globulus of the serum, or any other humour in the animal. Hence, 2. Those parts abounding most with these globules thus agitated, as the heart, liver, and head, will be the hottest of all others; and the denser the blood, *ceteris paribus*, the greater the heat, &c. 3. The quicker the contractions of the heart are repeated, the greater will the heat be. For the more probable cause of animal heat, see *Animal* HEAT.

The second manner of encreasing the effect of *elemental fire*, is, by throwing a quantity of moist or green vegetables, cut down while full of sap, into a large heap, and pressing them close down, the result of which is, that they grow warm, hot, smoke; and finally, will break out into flame.

The third way is by the mixture of certain cold bodies. Thus, water and spirit of wine first warmed, grow much hotter by the mixture; so any of the heavy, aromatic oils, as of cloves, cinnamon, saffafras, guaiacum, &c. mixed with spirit of nitre, grow exceedingly hot, and burst forth like volcanos; and the same may be said of spirit of nitre and steel-filings.

It is possible to produce *fire* and flame by the bare mixture of two cold liquors, in the following manner: take two drams of strong and fresh spirit of nitre prepared with oil of vitriol, and putting it into a clean and dry gallipot, set it under a chimney, then pour to it at once of the oil of cloves one dram, there will be immediately produced a loud noise and a considerable flame; and when that is gone, a dry resin is formed in the pot. See INFLAMMABILITY.

The like effect may be had from dry bodies. Thus, pure sulphur and steel-filings, well ground, and mixed in equal quantities, with water enough to make them into a dry paste, and laid an hour or two any where, even under ground, will smoke and emit flame, and that with the greater vehemence as it is more strongly pressed down.

The fourth is by PHOSPHORUS, which is a kind of fire-magnet prepared from the parts of animals, that imbibes and retains *fire* for many years.

But in all these ways it does not appear that any *fire* is excited or generated of what was not *fire* before; for if in a severe winter's day you rub a plate of gold briskly against another, they will both grow hotter and hotter by degrees, till at length they become red-hot, and at the point of melting; and yet all this time the plates lose nothing of their weight, but swell and grow bigger in all their dimensions.

Hence it follows, that the particles of the gold are not converted by the friction into *fire*, but that the *fire* existed before; and all the effect of the friction, &c. is to collect or bring together a quantity thereof before dispersed throughout the atmosphere.

In

In effect, there is no making or producing of *fire de novo*; all we can do is, of insensible, to render it sensible; i. e. to collect it out of a greater space into a lesser, and to direct and determine it to certain places. This is effected as above mentioned by *motion*, attrition, &c.

The sun also contributes very much to the bringing of *fire* to light, by means of his rapid motion round his axis, whereby the fiery particles every-where diffused are directed and determined in parallel lines towards certain places, where their effect becomes apparent.

Whence it is that we perceive the *fire* or heat when the sun is above the horizon; but when he disappears, his impression or preſſion being taken away, the *fire* continues diſperſed at large through the ethereal ſpace.

In effect, there is not leſs *fire* in our hemiſphere in the night-time than by day, only it wants the proper determination to make it perceived.

Another way of rendering it ſenſible, is, by collecting the parallel rays into a leſs compaſs, by means of convex glaſſes, or concave ſpecula. See BURNING-*glaſs*.

From theſe various ways of kindling *fire*, or producing heat in bodies, Dr. Franklin conjectures, that the *fire* exiſted in theſe bodies, though in a quieſcent ſtate, before it was by any of theſe means exerted, diſengaged, and brought forth to action and to view; and that it conſtitutes part, and even a principal part of the ſolid ſubſtance of bodies; ſo that kindling *fire* in a body is nothing more than diveſting the inflammable principle, and letting it at liberty to act in ſeparating the parts of that body, which then exhibits the appearances of ſcorching, melting, burning, &c. He alſo ſuppoſes that particles of *fire* joined to thoſe of air and water aſſiſt in raiſing vapours. See EVAPORATION. Franklin's Letters and Papers on Philoſophical Subjects, p. 412, &c. To the ſame purpoſe Boerhaave maintains, that this *elementary fire* is preſent every-where, in all bodies, in all ſpace, and at all times, and in equal quantities; for go where you will, to the top of the higheſt mountain, or deſcend into the loweſt cavern, whether the ſun ſhine or not, in the coldeſt winter, or the moſt ſcorching ſummer, by one or other, or all of the means above mentioned, may *fire* be collected. In a word, there is no aſſignable phyſical point without *fire*; no place in nature where the attrition of two ſticks will not render it ſenſible. So long as *fire* remains equable and undetermined in any place, it does not diſcover itſelf by any effect. In the ſevereſt weather we perceive no influence or effect of *fire*; when, at the ſame time, being collected and determined by attrition, it becomes manifeſt.

By changing *fire* out of its indeterminate ſtate, and impelling it in converging lines, its momentum is increaſed; witneſs the phenomena of burning-glaſſes.

But how attrition, crude vegetables, &c. contribute towards altering the direction, &c. of *fire*, does not eaſily appear.

On this *fire*, and the effects thereof above mentioned, depends all fluidity of humours, juices, &c. alſo all vegetation, putrefaction, fermentation, animal heat, and a thouſand other things.

2. But in what manner ſoever *fire* is collected in bodies, upon a ceſſation of the collecting cauſe, it ſoon diſappears again, unleſs it be ſupplied with a pabulum or fuel; and in this caſe it becomes *culinary fire*.

By pabulum or fuel of *fire*, we mean whatever receives and retains *fire*, and is conſumed, or at leaſt rendered inſenſible thereby.

The only pabulum of *fire* in all nature is the oil of ſulphur, or fat, or rather the phlogiſton of bodies; and bodies are only fuel, on account of the oil or phlogiſton they contain. For oil and ſulphur were names which the ancient chemiſts indiſcriminately gave to ſubſtances into the compoſition of which a great quantity of PHLOGISTON enters.

Hence, 1. All vegetables, not too moiſt, nor too dry, afford ſuch a pabulum, particularly thoſe which contain the greateſt quantity of oil, as balſamic and reſinous woods, &c. 2. All vegetable and animal coals are a proper pabulum for maintaining of *fire*, as being only the parts of vegetables and animals which have exhaled their water and ſalt, and retained the oil alone inhering in a black form in their earth. 3. All foſſil and bituminous earths, turfs, &c. 4. All mineral ſulphurs, whether pure, or joined with earth, ſtone, or metals, as pit-coal, &c. 5. The fat and dung of animals. And 6. Several productions of chemiſtry, as oils, inflammable ſpirits, *&c. alſo* a pabulum *for fire*. See COMBUSTION. This *fire* which burns combuſtible bodies requires air to ſuſtain it; which taken away, the *fire* is immediately diſſipated, as appears from the experiments *in vacuo*; except in the caſe of ſubſtances into the compoſition of which nitre enters; for theſe *will* burn *in vacuo*, in fixed air, and under water, as is evident in ſome rockets which are made for this purpoſe.

And yet *fire* does not immediately beat or endure the *air*, but always repels it, and by that means forms a kind of vault or aerial furnace all round, which by its weight, and the preſſure of the incumbent air, acts on all the particles or corpuſcles that would make their way through it, and thus retains the *fire*, and applies it to the combuſtible matter.

Hence, the heavier the air, the more vehement the *fire*; and accordingly, in ſtill cold weather we obſerve the *fire* to act with more violence than in warm weather.

But whether the air retains *fire* by its weight alone (which water itſelf would do) may be queſtioned; and whether its elaſticity does not contribute ſomething thereto; as alſo, whether there be not ſome farther unknown property in the air that has a ſhare in this effect may be doubted. Something of this kind one would ſuſpect from hence, that all air is not proper to maintain flame. Probably air is capable of receiving only a certain quantity of the phlogiſton or inflammable principle from bodies in a ſtate of combuſtion; and when it is ſaturated, it can no longer ſerve the purpoſe of maintaining flame. See AIR, *phlogiſticated*, and PHLOGISTON.

This *fire*, in a burning combuſtible matter, aſſumes a ſhining *fire* or flame, or both, according to the diverſity of fuel, and frequently alſo ſmoke, ſoot, and aſhes.

Shining or luminous *fire* ſeems to be *elementary fire*, attracted towards the part of the ſulphur or oil with ſuch force and velocity, as to move and ſhake them very violently, whirl them about, divide, and attenuate them, and thus render them volatile, and ready to be expelled; while in the mean time the air, making its vault all round, reſtrains and keeps them in, directs them to the ſulphur, and keeps them ſtill collected in their place or pabulum, while the combuſtible matter is diſſuſed all round. Flame ſeems to be nothing but a thin ſulphur, agitated, as before, by *elementary fire*; ſo that the *fire* is driven with a great motion around the revolving particles of the ſulphur. See FLAME.

Soot ſeems to be produced, when *fire* and ſulphur cannot break into a flame, being a ſort of coal conſiſting of a thick ſulphur, and an attenuated oil with earth and ſalt. See SOOT.

Smoke ſeems to be the combuſtible matter when it begins to be relinquiſhed by the *elementary fire*; for if this ſmoke be afterwards paſſed through a flame, it will itſelf become flame as *before*. See SMOKE.

Laſtly, aſhes are the earth and fixt which the *fire* leaves unhouſed. See ASHES.

Fire may be diſtinguiſhed into *ſhining* and *not ſhining*; for that there is *fire* which does not emit light, is evident hence, that a piece of iron taken out of the *fire* before it be red-hot ſhall yet give *fire* to ſulphur.

Shining fire, again, may be ſubdivided into two kinds: that which warms, as red-hot iron; and that which does not warm, as that obſerved in putrid fiſhes, rotten wood, &c. the oil whereof, beginning to be agitated and attenuated, produces light without any heat, ſo far as the thermometer may be a rule of judging.

Among the number of theſe lambent or innocent flames, is the ſhining of meat at certain times. It has been uſually ſuppoſed that this was owing only to the putrefaction of the meat, and that it never ſhone till ſtinking, or nearly ſo: but experience proves the contrary. We have in the Philoſophical Tranſactions an account of a piece of veal which was obſerved to ſhine the night after it was killed, and yet when eaten the day afterwards was perfectly ſweet; and a part of it that was kept by way of experiment continued good many days after. This is not of the nature of common *fire* or flame, and not only differs in not burning, but in this alſo, that it is not extinguiſhable in water. A perſon ſtriking this piece of veal had the flame covering his whole hand, and that continuing even when he had put it under water; but the wiping it with a towel turned it all off and deſtroyed it. It is not uncommon to find the guts of hogs when dreſſed for the making what they call chitterlings, and put into the pickle, ſhine in this manner. Some of the pieces while under this management uſually ſwim on the water, and others ſink in it. Thoſe which ſwim are the only ones that ſhine. The light upon them is as bright as the ſtrongeſt moonſhine, and may be communicated to a perſon's hand by rubbing the pieces on it, where it will continue to be bright a long time without any ſenſible heat. The face and hands of a perſon being rubbed over with one of theſe ſhining pieces of the chitterling, not only appear bright and ſhining, but are made to look conſiderably larger than they really are; and a perſon who had a mind to raiſe ſtories of ghoſts and apparitions might eaſily do it by covering the whole body of a man with this flame, and making him appear a *fiery* giant to all that ſaw him.

Mackrel in pickle will uſually become luminous in ſome degree a little before they ſtink, but it is rarely that the

light is great; and when it has once happened so, it is not eafy to hit the fame again on a fecond trial, though all the ingredients of the pickle are kept the fame in the ſtrongeſt manner. Worms are often found luminous on their ſurfaces in dark ſhells, yet the ſame worms are not always ſo; and what Pliny reports of the NYCTILA, and how far that has been found to be true, perhaps may not always hold, is future experiments. Philoſoph. Tranſ. N°174. ſee DACTYLOS.

One of the moſt regular kinds of lambent *fire* is that diſcovered at certain times on the ſea-water, and on other water in which there are fiſh or other ſea productions kept. We have in the Philoſophical Tranſactions an account of ſome water in which mackrel were boiled, and afterwards kept, which became blackiſh and thick after two or three days, and then would ſparkle on the touch of a finger. The fiſh alſo were luminous, eſpecially about the gills, and the water, when ſtirred about with the hand, would appear in bright ſtreaks over the whole ſurface, that the appearance was like that of water in motion, on which the moon ſhines very ſtrongly.

In the ſame manner the ſea-water in many places will ſparkle and ſhine on the breaking of its ſurface. Where a ſhip makes a good way in the night, at many ſeas, the whole breaking of the water will appear behind it as if on *fire*, ſparkling and ſhining all the way that it moves from the diſturbance in the wake of the ſhip. Philoſ. Tranſ. N°.

There does not always need the motion of a foreign body in the ſea to occaſion this ſort of phoſphorus, but the waves beating againſt one another will often occaſion it in great plenty; and ſometimes the waves waſhing againſt the rocks or againſt the ſhore, will yield a long courſe of light the whole night. This is no where to remarkable as at the Bahiſes, the ſhores there are often all on a *fire* to appearance, from the raſt cruſion of this luminous matter, as the waves waſh and break upon the ſhore.

This ſtreaming and ſparkling of the ſurface of the ſea is wholly owing to the peculiar quality of the water; and in general, the thicker and ſoulier the ſea is, the more light it affords on being ſtirred in the night. A cloth dipped in the ſea-water will ſometimes be ſticky as it dryſ in a ſolution of glue; in this caſe it will afford much brighter and more luminous ſparks in the drying: and this fat water will give much more *fire* from the motion of the ſhip than any other. In many places the ſurface of the ſea is found covered with fiery mattes of a reddiſh or yellowiſh colour, looking like ſaw-duſt, and ſeeming to be the ordure or excrement of ſome ſea-animals. This matter is always of a viſcous nature, and the ſea-water is viſcous and glutey wherever this is found, and gives more light on the moving than any other water. In the Northern ſeas there are ſometimes ſeen whole banks, as it were, of this matter, the ſurface of the ſea appearing wholly covered with it for ſeveral leagues; and this is often luminous all over in the night though not ſtirred by any ſhip, or even by the motion of any fiſh. Many of the ſea fiſh have a viſcous matter about their gills, eſpecially when they have been ſome time dead. Theſe, when kept in ſea-water, have ſo much of this luminous property, that all that part appears as ſoon as taken up of the brightneſs of a flaming coal, and gives a light which is eaſy to read by. A piece of ſtick rubbed on the gills of theſe fiſh will become luminous wherever it has touched them, and will continue ſo as long as it retains any of the moiſture, but as that dries the light will fade and go off; and it may be revived again on touching the fiſh a ſecond time. Obſerv. ſur l'Abe, p. 289. Jones's Abr. Philoſ. Tranſ. vol. v. part ii. p. 213. See a more particular account and explication of this phenomenon under the article *Luminouſneſs of the Sea*.

Of *ſhining*, and at the ſame time *warming fires*, the principal is that of the ſun, as it is called; though, whether the *fire* be really emitted from the body of the ſun, or whether it be only the common vague univerſal *fire* determined by the ſun, is not eaſy to ſay; this *fire* we more uſually conſider under the denomination of light. This ſolar *fire*, in calcining certain bodies, makes ſome addition to the weight thereof.

Thus, antimony expoſed in the focus of a burning-glaſs will ſmoke a conſiderable time, and the greateſt part of it will ſeem to evaporate in fumes; but, if afterwards tried by the balance, it will be found to have gained in weight; and if it be again applied in the focus of a larger glaſs, it will again emit fumes, and yet ſtill be increaſed in weight.

Du-Clos found, that a pound of regulus of antimony, finely powdered, and expoſed to the focus of a burning-glaſs, acquired in the ſpace of an hour an increaſe of weight equal to a tenth part of the former weight: the ſame fact was alſo obſerved by Homberg with regard to antimony, and by Du-Hamel in ſeveral other mineral.

Zumbochius found that lead liquified in the focus of a large ſpeculum, and afterwards calcined and converted into glaſs, gained an increaſe of weight, though part of it evaporated in ſmoke. Nor is this increaſe of weight peculiar to ſubſtances calcined by ſolar *fire*. It is well known that 100 lb. of lead calcined in a fierce *fire* yields 110 lb. of minium. Hellot, by reducing 4 lb. of zinc into a calx, obtained 5 lb. 14 ounces of very white and fine calx, 2 ounces and 5 drams of coarſer and whitiſh calx, and an ounce of earth, though in the mean while part of the metal had eſcaped in ſmoke. Geoffroy found that biſmuth acquires in calcination an increaſe of $\frac{1}{4}$th of its original weight. The calx of tin is alſo known to gain $\frac{1}{7}$th in weight. An ounce of filings of copper expoſed to a wheel-*fire* for the ſpace of three hours, and afterwards left to cool, had acquired an increaſe of 49 grains. Iron, according to the experiments of Mr. Scheffer, publiſhed in the Swediſh Tranſactions for the year 1757, receives by complete calcination an augmentation of one third of its weight; and it has been lately obſerved by Profeſſor Brugmans, in his Obſervationes Academicæ de Affinitatibus Magneticis, publiſhed at Leyden in 1778, that a quantity of the filings of iron which weighed one ounce or 480 grains before it was expoſed to the *fire*, after ſeven calcinations, increaſed in weight 140 grains; in the firſt calcination, which was the weakeſt, and in which all the filings were not red-hot in the crucible, the weight of the ounce increaſed 3 grains; in the ſecond, in which the phlogiſton was inflamed, and the whole maſs had a white heat, the weight of the ounce was increaſed during the ſpace of half an hour 34 grains; in the third, during a like interval, 50 grains; in the fourth, 18; in the fifth, 15; in the ſixth, 7; in the ſeventh, 6; in the eighth, 9; in the ninth, in a new crucible, 5; in the tenth and eleventh, in the ſame crucible, one each. From other experiments this learned profeſſor concludes, that the condition which is neceſſary in order to the augmentation of the weight of iron by *fire*, is, that the phlogiſton be previouſly conſumed; and he is of opinion, that the ſame rule holds with reſpect to the augmentation of weight in other metals. M. de Buffon, in the firſt volume of his Supplement to his Natural Hiſtory, 1774, recites ſome experiments which he had made on coherent maſſes of iron, and from which he inferred the ponderoſity of *fire*. In one of his trials he found a ball of iron, which weighed 49 lb. 9 ounces when cold, to weigh when heated to a white heat 49 lb. 11 ounces, which gives an augmentation of 19$\frac{1}{2}$ grains to the pound. Theſe concluſions of Buffon have been ſince invalidated by ſome experiments of Dr. Roebuck and Mr. Whitehurſt: the former uſed two accurate balances; one of which, with the weight of a pound, would turn with one-tenth of a grain; and the other with a weight of half an ounce in each ſcale, would turn with the one hundredth part of a grain. A piece of iron of nearly one pound weight having received a white heat, was found to have loſt ſcarce a grain when it was cold; and another piece of about five penny-weights weighed ſomewhat more when it was cold than when it was hot. By other experiments ſince made in the preſence of ſeveral members of the Royal Society, it appeared that a cylinder of iron brought to a white heat, and then weighing 55 pounds, on being ſuffered to cool, ſeemed gradually to acquire weight; and about twenty-two hours after it had begun to cool, was found to have increaſed in weight 6 penny-weights, 17 grains. The beam uſed on this occaſion was ſo nicely conſtructed, that, when it was loaded with the great weight above mentioned, the ſcale evidently turned with 4 grains.

The experiments of Mr. Whitehurſt were made with ſmall maſſes; but with a balance ſo nice as to be ſenſibly affected by the two thouſandth part of a grain. A penny-weight of gold made red-hot, and brought nearly to a ſtate of fuſion, became apparently lighter; but on cooling, its former weight was perfectly reſtored. The ſame quantity of iron likewiſe ſeemingly loſt weight on being equally heated; but its weight was viſibly augmented on becoming cold.

Mr. Whitehurſt accounts for the apparent fallacy in M. de Buffon's experiments, by ſuppoſing that the heat of the large maſs of iron employed by him had a greater effect on that arm of the beam from which it was ſuſpended than on the other; and that by expanding or lengthening the former in a greater degree than the latter, it produced the preponderancy on that ſide which M. de Buffon aſcribed to the particles of *fire* contained in the metal. Philoſoph. Tranſ. vol. lxvi. part. ii. art. 31. p. 509. art. 38. p. 575

M. Margraaf, in his experiments on PLATINA, found, that after expoſing 2 ounces of crude platina in a ſcorifying diſh under a muffle to a ſtrong *fire* for two hours, and ſuffering it to become cold, it weighed 2 ounces and 10 grains, or one part in ninety-ſix more than it did at firſt;

firſt; and an ounce of platina in a covered crucible, placed in a melting furnace, and expoſed between three and four hours in the ſtrongeſt *fire* of all the furnaces in his laboratory, weighed near 6 grains, or about one part in eighty more than at firſt. Acta Chemica, tom. ii. p. 113. M. Macquer put an ounce of platina into a German crucible, and expoſed it to a ſtrong *fire* for fifty hours; and on weighing the platina after the operation, it was found to be increaſed 14 grains, or allowing 576 grains to the French ounce, about one part in forty-one. The ſame platina ſubmitted to another ſimilar operation, received a farther increaſe of 2 grains; the augmentation in all being 16 grains, or one part in 36. This increaſe of weight he ſuppoſes to be owing to the calcination of ſome heterogenous ſubſtances mixed with the platina.

Dr. Lewis, having picked out from platina 360 grains of the larger and brighter particles, and the ſame quantity of the blackiſh duſt ſeparated from it by a ſieve, put the two parcels in two ſmooth ſcorifying diſhes, and kept them under a muffle in very ſtrong heat for five hours, and when cold the picked platina weighed with great exactneſs was found to have gained 2 grains, or one part in 180, while the duſt was increaſed near 9 grains, or one part in 40. Comm. Philoſ. Techn. p. 462. The concluſion which ſome philoſophers have drawn from theſe experiments, and others of a ſimilar nature, is, that *fire*, by adhering to certain ſubſtances increaſes their weight, and is therefore ponderous like other bodies; an opinion which ſeems to have been ſuggeſted even by the ancients. See Lucretius, lib. ii. v. 185. But howſoever the queſtion concerning the nature and gravity of *fire* may be determined, the increaſe of weight acquired by calcined ſubſtances is moſt ſatisfactorily accounted for by the modern diſcoveries withregard to fixed air. See CALCINATION and *Potential* HEAT. See on the ſubject of this article Boerhaave's Chemiſtry, vol. i. part 2. of *Fire*, and Muſchenbroeck's Introd. ad Phil. Nat. tom. ii. ſect. xxiii. p. 669. &c. ed. 1762.

Beſide the ſolar, there is likewiſe a ſubterraneous *fire*. This appears in digging under-ground; for the firſt globe next to the ſurface is warmed by the heat of the ſun, and as you go deeper you will find it colder; whence, even in hot countries, they have conſervatories of ice at ſome depth under-ground, till, arriving at a certain depth, viz. forty or fifty feet, it begins to grow warmer, ſo that no ice can there ſubſiſt, and at a yet greater depth, it is ſo hot as to take away reſpiration, extinguiſh candles, &c. and if the miner will venture farther, and carry a candle along with him, he frequently ſets the whole place in a flame, the ſulphureous fumes, rendered volatile by the ſubterraneous *fire*, catching flame from the candle.

Whence it is alleged by ſome that there is another ſource of *fire*, or, as it were, another ſun in the boſom of the earth which gives motion and life to every thing growing in or upon the globe, and even that the centre of the earth is mere *fire*, which *fire* is likewiſe argued to be perpetual, from volcanos or burning-mountains, which have been known to caſt up *fire* from the earlieſt account of time. See HEAT and VOLCANO.

There are two great *fires*, therefore, the higher or ſolar, and the lower or ſubterraneous.

The effects of this laſt ſeem wholly the ſame with thoſe of the common culinary *fire*; for burnt coals, cinders, and melted minerals are thrown out by the burning mountains; and hot ſprings, ſteams, vapours, &c. are found in ſeveral parts of the globe, riſing nearly in the ſame manner as if they were produced by the heat of a common furnace. Whence there is little room to doubt but that the ſubterranean *fires* are not like the celeſtial or ſolar but the culinary.

Martin in his Atlas, tells us, that there are pits of natural *fire* in China which are capable of dreſſing meat, but will not conſume wood; but we have no authentic teſtimony of any eye-witneſs to this ſtrange fact.

FIRE, in *Chemiſtry*, is the great inſtrument by which moſt of the operations of that art are performed.

The kind, degree, direction, &c. of *fire* are things the chemiſt is principally to attend to. The diverſity of *fire* makes a great difference in the reſult of the experiment; ſo that the ſame effect, *e. gr.* ſhall not ariſe, if an experiment be made with the *fire* of ſpirit of wine and that of pit-coal.

And to this cauſe Mr. Boyle, in his Treatiſe of the unexpected Failure of Experiments, attributes it, that a great many experiments ſucceſsfully tried by ſome have not ſucceeded with others.

The *fires* chiefly required by the chemiſts are ſuch as yield no faces or remains, no ſalt nor ſmoke; and ſuch alone are thoſe of the ſun and ſpirit of wine. Thoſe which come next in purity are oils diſtilled *per ſe*, which loſe their earth and ſalt by their boiling and agitation in the water, ſo that the oftener the diſtillation is repeated, the purer they are rendered. After theſe the beſt is tuſſ.

Indeed, the very manner wherein the *fire* is blown is found to have ſome effect. Thus, Acoſta, lib. iv. cap 5. relates, that in Peru, when they would melt and ſeparate their ſilver from the earth, &c. if the *fire* be blown up with bellows, the ſuſion will not ſucceed; nor will any other *fire* do but that blown by the wind ruſhing from the fall of ſome water; ſo that they are forced to have recourſe to large holes made to the feet of large mountains, where there are cataracts to convey the wind generated by the fall of water to their works.

The degree of *fire*, or the collection and direction of *fire* to the degree proper for each operation, conſtitutes almoſt the whole art of chemiſtry.

Now the greater or leſs force of *fire* depends altogether on a greater or leſs quantity thereof collected into a focus; for as to its motion it does not ſeem in our power to alter it, or to make any increaſe or diminution of the force of the *fire* on that account.

The chemiſts in all ages have been accuſtomed to ſpeak of the degrees of *fire*, which they uſually divide into four; but very little accuracy was found on this head till the method was diſcovered of applying the thermometer of Fahrenheit to the meaſurement of the progreſs of heat by certain and invariable rules. On this baſis Boerhaave has eſtabliſhed the chemical doctrine of the power of *fire*, and divided it into ſix degrees; and theſe are the degrees of *fire*, which our chemiſts allude to, when they now mention the force of *fire* in their operations.

The firſt degree is that by which nature performs the office of vegetation in plants, and by which chemiſtry imitates and does the like. This commences from the higheſt degree of cold, which in Fahrenheit's thermometer is marked at 1°, and ends at 86°, ſince in this whole interval vegetables of one kind or other give indications of life and growth; ſo that if all the plants with which we are at preſent acquainted be examined, by the degrees of heat contained within theſe limits, we ſhall find ſome plant or other that comes to maturity in almoſt every one of theſe intermediate degrees.

Hence it appears probable, that the chemiſt, by duly conducting this degree of heat in an artificial flow, might contrive to cheriſh and forward the vegetation of various plants; and in the offices of chemiſtry a furnace might be made for raiſing any degree of heat within theſe limits, on which a veſſel of water might be ſet, and a thermometer applied to it, the riſe or fall of which indicates the degree of heat required. Glaſs veſſels placed in the water thus temhered might be uſed for containing thoſe ſubſtances which are to undergo this degree of *fire*. Thus, the fragrant ſcent of roſes may be communicated to oil, by putting the inodorous and inſipid oil of olives in a tall clean chemical glaſs, and digeſting it in a heat of 56 degrees with the moſt fragrant roſes gathered laſt as they are opening in the morning: the application of a ſimilar degree of heat would impregnate alcohol with the pureſt ſpirit of ſaffron.

The ſecond degree of *fire* may be commodiouſly meaſured by the heat that is at ſome time or other obſerved in healthy bodies, and may be ſuppoſed to commence at the 40th degree of the thermometer, and to end about the 94th. Animals may ſubſiſt if their humours have any degree of heat in them between theſe limits. The eggs of inſects ſubſiſt unhurt during hard winters, and hatch in the ſucceeding ſpring. Fiſhes, both of the ſea and of rivers, live in water which is only 33 degrees warm; and fiſhes that have lungs, and all reſpiring animals in a ſtate of health communicate to their humours a warmth of 92 degrees; and therefore, the limits of this degree are fixed at 33 and 94. Within the compaſs of this heat are included the vital actions of animals, the fermentation of vegetables, and the putrefaction both of vegetables and animals; and likewiſe the generation, breeding, hatching, birth, and nutrition of animals. Some determine the ſtandard of this heat by applying a thermometer to a hen brooding on her eggs, and by keeping a *fire* continually to this degree, chickens have been hatched. This degree of heat is employed by chemiſts to prepare their elixirs, volatile alkaline ſalts, and their tinctures. However, it appears from later obſervations that the limits of *animal* HEAT are conſiderably greater than thoſe which the celebrated profeſſor has above ſtated.

The third degree of heat extends from the 94th degree of the thermometer to the 212th, at which water generally begins to boil. Through this ſpace the water and native ſpirits are ſeparated from all vegetables and animals, and the reſiduum becomes dry and durable. The eſſential oils of plants become volatile; the ſalts and oils in the freſh juices of animals are ſcarcely raiſed, but the

juices dry into a thick, hard, brittle, insipid, inodorous substance, which will keep for years without any considerable alteration. This degree of heat is for the distillation of oils and medicinal waters of vegetables. The sanguineous serous juices of animals coagulate in boiling water into masses that may be cut asunder; all their solids are converted into a thick tenacious liquid, and it is consequently destructive to all animals. See *Animal* HEAT.

The fourth degree of heat may be reckoned from the degree 212 to 600; within which limits all oils, saline lixivia, mercury, and oil of vitriol are distilled; lead and tin will alſo melt and mix together. The oils, ſalts, and ſaponaceous juices of animals and vegetables are rendered volatile and acrid, and become more or leſs alcaleſcent: their ſolid parts are calcined, and loſe their diſtinguiſhing qualities and proper virtues; and with this degree of *fire* boſh ſulphur and ſal ammoniac are ſublimed.

The fifth degree of *fire* is that which fumes the other metals, beginning at the degree 600, and terminating at the degree of heat capable of melting iron. Glaſs, gold, ſilver, copper, and iron remain long unchanged; all other fixed bodies become white with this heat, the fixed ſalts of vegetables and foſſils melt, loſe moſt of their oils, acquire an increaſing alcaline acrimony, and with ſand or flint are converted into glaſs. Lime-ſtones are calcined, and all other bodies either vitrify or become volatile, and are diſſipated into the air.

The ſixth and higheſt degree of *fire* is that produced either by a lens or a burning ſpeculum, which hardly any ſubſtance is able to reſiſt; and even the gold and diamond, and platina are conſiderably altered by it.

The moſt uſual effect of *fire* is the vitrification of fixed bodies; and this, ſays Boerhaave, the ancient magi of the Eaſt ſeems to have been appriſed of, as they predict the deſtruction of the world by *fire*, and its mutation into tranſparent glaſs. Boerhaave by Dallow, ubi ſupra, p. 241, &c.

This laſt degree was firſt diſcovered in the year 1690 by Mr. Tſchurnhauſen, whoſe burning glaſs rendered every thing, even gold itſelf volatile.

Beſides theſe ſix degrees, the chemiſts have ſeveral intermediate ones; all which, however, may be eaſily reduced to the former.

As the *digeſting fire*, or *water egal*, which is the heat of a dunghill.

The *balneum Mariæ*, *arenæum*, &c. explained under the article BALNEUM.

The *naked* or *immediate fire*, which is the common *fire* applied under a veſſel.

The *fire* of a lamp, which is moderate and equal, and may be increaſed by the addition of more wick, uſed by chamelters, &c.

The *ſolar fire*, which is lighted all round a crucible or other veſſel to heat it all alike.

That called by *ſuppoſition*, which is when the veſſel is not only encompaſſed round, but covered over with *fire*.

The *reverberatory fire*, when it is in a furnace cloſe at top by which the *fire* is reflected back, and all round upon the veſſel.

The *melting* or *faſing fire*, for the ſolution and calcination of metals and minerals.

The *glaſs-houſe fire*, for the vitrifying of the aſhes of vegetables.

And the *Olympic fire*, which is that of the ſun collected in the focus of a burning mirrour.

Heil-fire is a term denoting the greateſt degree of heat employed by the manufacturers of ſal ammoniac in Egypt.

To the ſeveral degrees of *fire* required, ſeveral forms of furnaces are accommodated; which ſee under the article FURNACE.

There are five principal ways of altering the degree of *fire*.

For *fire* differs 1. According to the weight of the pabulum or fuel, it being a rule, that the heavier the fuel or combuſtible matter is, the more vehement, *cæteris paribus*, is the *fire*. Thus, ſpirit of wine affords a weaker and leſs deſtructive *fire* than oil; and this than pitch, and ſo on: the heavier and groſſer, ſtill the fiercer.

2. According to the quantity of the pabulum or fuel.

3. According to the diſtance of the *fire* from the object; it being a rule, that the heat of the *fire* at different diſtances is reciprocally as the ſquares of thoſe diſtances.

4. By the introducing or blowing of air into the *fire*, it being a rule that the ſtronger the current of air or wind is, provided it be not ſo ſtrong as to break the vereal tumix or vault incumbent on the *fire*, the more is the *fire* increaſed. For a brisk blowing puts the minute parts of the pabulum into a greater motion; whence the greater attrition ariſes, and of conſequence more *fire* is collected.

5. According to the ſolidity or reſiſtance of the medium between the *fire* and the object; for the more ſolid the medium, the greater quantity of heat, *cæteris paribus*, does it receive from the *fire* and communicate to the object.

Thus, a vapour-bath communicates much leſs heat to the bodies diſtilled by it than a water-bath, and this again leſs than a bath of ſteel-filings; for all bodies expoſed to the *fire* grow hot in proportion to their ſpecific gravities. Thus, if a piece of metal be put in water, and both ſet over the *fire*, while the water only grows lukewarm the metal ſhall be ſo hot as to be paſt touching; and thus, a key in a perſon's pocket ſitting near the *fire* ſhall frequently be very hot, while his cloaths themſelves have not any ſenſible warmth. Indeed, this rule admits of ſome exceptions; for we have oils lighter than water, which yet admit of triple the degree of heat before they boil.

It is a great controverſy in chemiſtry, whether *fire* when applied to bodies only ſeparates and diſſolves them, or whether it does not alſo really and abſolutely change them.

Mr. Boyle, in his Sceptical Chemiſt, we think, has abundantly proved, that *fire* really alters bodies, and that the parts or elements procured from bodies by *fire* did not exiſt as ſuch in the bodies themſelves.

Add, that *fire* does not only ſeparate and decompound, but it alſo compounds and mixes different bodies ſo intimately together, that the new formed ſubſtance appears perfectly ſimple, and is not liable to any alteration from its power afterwards. Boerhaave.

FIRE, in *Medicine* and *Surgery*, is uſed in the ſame ſenſe with cautery. See CAUTERY and CAUSTIC.

Fire alſo gives the denomination to divers diſeaſes, as

FIRE, *St. Anthony's*, by phyſicians more uſually called *erypelas*. See ERYSIPELAS and ANTHONY.

FIRE, *walking*, called alſo *Will-with-a-wiſp*, *Jack-in-a-lantern*, *ignis fatuus*, &c. See IGNIS *fatuus*.

FIRE, in *Theology*, is frequently underſtood of the puniſhment of the wicked after death. See HELL.

It is ſuppoſed the world will periſh at laſt by *fire*. See CONFLAGRATION.

God has made ſeveral reveſtations of himſelf under the appearance of *fire*; he appeared to Moſes under the form of a *fire* burning in a buſh; the Holy Ghoſt deſcended on the apoſtles in tongues of *fire*; and the camp of the Iſraelites was guided and conducted in the night time by a pillar of *fire*.

The Perſians adored God under the image or repreſentation of *fire*, becauſe it is *fire* that gives motion to every thing in nature. They are ſaid to have in that empire *fires* ſtill ſubſiſting, which have burnt many thouſand years. See FIRE *everlaſting*, GABRES, and MAGI.

The Hebrews kept up the *holy fire* in the temple. This *holy fire* deſcended from heaven, firſt upon the altar in the tabernacle at the conſecration of Aaron and his ſons to the prieſt-hood, Lev. ix. 24. and after wards it deſcended anew on the altar in the temple of Solomon, at the conſecration of that temple. 2 Chron. vii. 1. And there it was conſtantly maintained by the prieſts day and night, without ſuffering it ever to go out; and with this all the ſacrifices were offered that required *fire*. This *fire*, according to ſome of the Jewiſh writers, was extinguiſhed in the days of Manaſſeh; but the more general opinion among them, is, that it continued till the deſtruction of the temple by the Chaldeans: after that it was never more reſtored; but inſtead of it they had only common *fire* in the ſecond temple.

The VESTALS were appointed expreſsly to keep up the ſacred *fire* of the Romans.

Vulcan was worſhipped among the ancients, and particularly the Egyptians, as the inventor of *fire*; and Boerhaave has made it highly probable, that the Vulcan of the heathens was the Tubal-Cain of the Hebrews, the firſt who appears to have known the uſe of *fire*, and to have applied it in the fuſion of metals, and other preparations of chemiſtry.

FIRE, in the *Manage*. To give the *fire* to a horſe is to apply the firing-iron red-hot to ſome preternatural ſwelling in order to diſcuſs it, which is oftentimes done by clapping the firing-iron upon the ſkin without piercing through. We give the *fire* to FARCY knots, by running a pointed burning-iron into the ulcers. We likewiſe give the *fire* for wrenches of the paſterns. See FIRING-*iron*.

FIRE, in the *Military Language*, is ſometimes applied to the *fires* lighted in an army in the night-time.

But the term *fire* or *firing* is more frequently uſed for the diſcharge of the *fire-arms*, or the ſhot made on the enemy from the artillery, &c. And accordingly it is uſed as a word of command to ſoldiers of all denominations to diſcharge their *fire-arms*, grenades, cannon, &c. The

fire of the infantry is by a regular discharge of their *fire*-locks, by platoons, divisions, &c. that of the cavalry with their fuzees and pistols; and that of the place besieged from their artillery. See EXERCISE and PLATOON.

In fortification, the *fire of the place* denotes the flank, or that part of the curtain where the line or defence terminates, from whence they *fire* to defend the opposite face of the bastion.

FIRE-*arrow* is a small iron dart furnished with springs and bars, together with a match impregnated with powder and sulphur, which is wound about its shaft. It is used by privateers and pirates to *fire* the sails of the enemy, and for this purpose is discharged from a musket or a swivel-gun. The match being kindled by the explosion, communicates the flame to the sail, against which it is directed where the arrow is fastened by means of its bars and springs. As this is peculiar to hot climates, particularly the West Indies, the sails being extremely dry are instantly set on *fire*, and the *fire* is conveyed to the ships, rigging, and finally to the cedar itself.

FIRE-*arms*. See ARMS.

FIRE-*ball*, a composition of meal-powder, sulphur, saltpetre, rosin, pitch, &c. about the bigness of a hand-grenade, made of an iron shell, filled and covered over with several coats of the above mixture, the last coat being of grained powder. Thick brown paper made into the form of a shell shaped to the size of the mortar, and filled with an equal quantity of sulphur, pitch, rosin, and meal powder well mixed and put in warm, will answer the purpose as well as any thing else. This is to be thrown into the enemies works in the night-time to discover where they are; or to *fire* houses, galleries, or blinds of the besiegers. The balls used for this intention are prepared with mealed powder, saltpetre, sulphur, rosin, fleet or iron filings, fir-tree saw-dust boiled in saltpetre ley, and birch wood charcoal, well tempered into a shell, having earthen balls filled with small barrels loaded with musket-balls, and immersed in melted pitch, rosin, and turpentine oil. They are sometimes armed with spikes or hooks of iron, that they may not roll off, but stick or hang where they are desired to have any effect. See BALLS.

FIRE-*hare*, in our *Old Writers*, is used for a beacon. *Quod sine dilatione levare & reparare fac, signa & fire-hares, super montes altiores in quolibet hundredo, ita quod vota patria per ista signa, quibuscunque incolis patriæ, præmuniri possit.* Ordin. 26 Edward. Temp. Edw. II.

FIRE-*barrels*. See BARRELS. Those used to FIRE *ships* ought to be of a cylindric form, as most suitable to contain the REEDS with which they are filled, and more convenient for throwing them between the sails in the *fire*-room. The inside measure should not be less than 21 inches, and 30 inches are sufficient for their length. The bottom parts are first well fenced with short double-dipped reeds pieced upright; and the remaining vacancy is filled with *fire-barrel* composition, being a mass of corned powder, pitch, and tallow, well mixed and melted, and poured over them. The proportion and quantity of ingredients for one barrel are 150 lb. corned powder, 60 lb. of pitch, and 10 lb. of tallow; and the priming composition for one barrel is 100 lb. of corn powder, 50 lb. of saltpetre, 40 lb. of sulphur, 8 lb. of rosin, and three pints of oil. There are five holes of three-fourths of an inch in diameter, and 3 inches deep, formed in the top of the composition while it is warm; one being in the centre, and the other four at equal distances round the sides of the barrel. When the composition is cold and hard, the barrel is primed by filling those holes with fuse-composition, which is firmly driven into them, so as to leave a little vacancy at the top to admit a strand of quick match twice doubled. The centre hole contains two strands at their whole length, and every strand must be driven home with mealed powder. The loose ends of the quick-match being then laid within the barrel, the whole is covered with a dipped CURTAIN, fastened on with a hoop that flips over the head of the barrel, to which it is nailed. These barrels should be made very strong, not only to support the weight of the composition before firing, when they are moved from place to place, but to keep them together whilst burning; for if the staves are too light and thin, so as to burn very soon, the remaining composition will tumble out and be dissipated, and the intention of the barrel, which is to carry the flame aloft, will be frustrated. Falconer's Mar. Dict. and Miscellaneous, vol. v. p. 301.

FIRE-*blasts*, in *Agriculture* and *Gardening*. See BLASTS, and Miller's Statics, vol. i. p. 36.

FIRE, *Isle*. M. Maubuel has a dissertation on the origin of *fire-arms*, wherein he endeavours to make it appear that they were unknown to the ancients, and consequently must be a modern invention.

He does not deny that the ancients had rejoicings on occasion of the conclusion of a peace or alliance, or the news of a victory's being obtained against their enemies, on the birth-day, proclamation, or marriage of their prince; as also when they recovered from a dangerous sickness; but according to him, the *fire* on all these occasions served only to burn the victims or the incense; and as these sacrifices were mostly offered in the night-time, the illuminations were only intended to give light to perform the ceremonies. Hist. Acad. Inscript. tom. ii. p. 430, &c.

FIRE *locks*, feel for necessary firings, which, by the common journals, tenants may take out of the lands granted to them.

FIRE-*locks*. Church-wardens in London, and within the bills of mortality, are to fix *fire-locks* at proper distances in streets, and written marks near them, and to keep in every house thus marked an instrument or key for opening the plug, and a large engine and hand-engine for extinguishing *fire*, under the penalty of 10*l*. The turn-cock whose water shall come first into a main pipe at a *fire* shall have 10*l*. the full engine that is brought first shall entitle to 30*l*. the second to 20*l*. and the third to 10*l*. 6 Ann. cap. 31. 13 Geo. III. cap. 78. To prevent *fires*, it is required that workmen in the city of London, &c. build all front and rear walls of brick or stone; and that the front walls be 18 inches above the gutter, and coped with stone, tiles or brick; and party walls between house and house, those belonging to houses the expence of building which is more than 120*l*. to be of the thickness of 2 foot 9 inches, or 21 bricks in the lowest story, and of 2 bricks, or 1 foot 5½ inches from thence to the garret floor; and from the garret upwards 1½ brick, or 13 inches, and to be carried up to the full height of 18 inches above the adjoining gutters; and it is also required, that no timbers, except the girders, binding and trimming joints, and the templers under the same, shall be laid into such party-wall; and that there shall be 5 inches of solid brick work left at or between the ends of all beams, wall-plates, and bond timbers. See BUILDING, and stat. 7 Anne, cap. 17. 11 Geo. I. cap. 28. 37 Geo. II. cap. 36. and 4 Geo. III. cap. 14. And on the breaking out of any *fire*, all the constables and headles shall repair to the place with their staves, and be aiding in putting out the same, and causing people to work, &c. No action shall be had against any person in whose house or chamber a *fire* shall begin, 6 Anne, 10 Anne, cap. 14. But if such *fire* happens through negligence of any servant, such servant shall forfeit 100*l*. to be distributed among the sufferers; or, in default of payment, shall be committed to some workhouse, there to be kept to hard labour for eighteen months. See ARSON.

All the laws relating to the prevention, &c. of *fire*, are reduced into one statute, and former statutes repealed by 12 Geo. III. cap. 73.

FIRE-*damp*, in *Natural History*. See DAMP.

FIRE-*eaters*. We have a great number of mountebanks who have procured the attention and wonder of the public, by eating of *fire*, walking on it, washing their hands in melted lead, and the like tricks.

The most celebrated of these was our countryman Richardson, much talked of abroad. He feared, as related in the Journals des Sçavans, of the year 1680, consisted in a pure spirit of sulphur, wherewith he rubbed his hands and the parts that were to touch the *fire*, which burning and consuming the epidermis, harden'd and enabled the skin to resist the *fire*.

Indeed, that is no new thing; Amb. Paré affures us he had tried on himself, that after washing the hands in urine, and with unguentum album, one may safely wash them in melted lead.

He adds also, that by washing his hands in the juice of onions he could bear a hot shovel on them while it melted lead.

FIRE, *electrical*. See ELECTRICITY.

FIRE-*engine* is a machine for extinguishing accidental *fires* by means of a stream or jet of water. The common squirting *fire-engine* consists of a sucking pump placed in a circular or cylindric vessel of water, and wrought by two levers that act always together. During the stroke, the quantity of water raised by the piston of the pump spouts with force through a pipe joined to the pump-barrel, and made capable of any degree of elevation by means of a yielding leather pipe, or by a ball and socket turning every way, screwed on the top of the pump. The vessel containing the water is covered with a strainer, which prevents the dirt and filth poured into it with the water from choaking the pump-work. Between the strokes of this engine the stream is discontinued

for want of an air-veſſel. However, in ſome caſes, engines of this conſtruction have their uſe, becauſe the ſtream, though interrupted, is much ſwifter than when the engine is made to throw water in a continued ſtream. The beſt engine of this latter kind is that of Mr. Newſham, formerly an engine-maker in London. A perſpective view of the whole engine ready for working is repreſented in *Tab. Hydraulics*, &c. *fig.* 3. This engine conſiſts of a ciſtern A B about three times as long as it is broad, made of thick oaken planks, the joints of which are lined with ſheet-copper, and eaſily moveable by means of a poſe and croſs bar C on the fore-part of the engine, which is ſo contrived as to ſlide back under the cover of the ciſtern, and of four ſolid wheels, two of which are ſeen at D and E. The hind axle-tree, to which the wheel E and its oppoſite are fixed, is faſtened acroſs under the bottom of the ciſtern; but the fore axle-tree, bearing the wheel D, &c. is put on a ſtrong pin or bolt ſtrongly faſtened in a horizontal ſituation in the middle of the front of the bottom of the ciſtern, by which contrivance the two fore-wheels and their axle-tree have a circular motion round the bolt, ſo that the engine may ſtand as firm on rough or ſloping ground as if it was level. Upon the ground next to the hind part of the engine may be ſeen a leathern pipe F, one end of which may be ſcrewed on and off upon occaſion to a braſs cock at the lower end of the ciſtern; the other end is immerſed in the water, ſuppoſed by a pond, for inſtance, &c. and the pipe becomes a ſucking pipe for ſupplying the pumps of the engine by its working, without pouring water into the ciſtern. To the hind part of the ciſtern is faſtened a wooden trough G, with a copper grate for keeping out ſtones, ſand, and dirt, through which the ciſtern is ſupplied with water when the ſucking pipe cannot be uſed. The fore part of the ciſtern is alſo ſeparated from the reſt of its cavity by another copper grate, through which water may be poured into the ciſtern. Thoſe that work the pumps of this engine move the handles viſible at the long ſides up and down, and are aſſiſted by others who ſtand on two ſuſpended benches, throwing their weight alternately on each of them, and keeping themſelves ſteady by taking hold of two round horizontal rails, H, I, framed into four vertical ſtands, which reach to the bottom of the ciſtern, and are well faſtened to its ſides. Over the hind bench there is an iron handle or key K, ſerving to open or ſhut a cock placed under it on the bottom of the ciſtern, the uſe of which we ſhall explain in the ſequel of this article. L is an inverted pyramidal box or caſe which preſerves the pumps and air veſſel from damage, and alſo ſupports a wooden frame M, on which ſtands a man, who, by ſtraddling, and turning about the ſpout N, directs the ſtream of water as occaſion requires. This ſpout is made of two pieces of braſs pipe, each of which has an elbow; the lower is ſcrewed over the upper end (ſee *fig.* 5.) of the pipe that goes through the air-veſſel, and the upper part ſcrews on to the lower by a ſcrew of ſeveral threads, ſo truly turned as to be water-tight in every ſituation. The conic form of the ſpouting-pipe ſerves for wire-drawing the water in its paſſage through it, which occaſions a friction that produces ſuch a velocity of the jet as to render it capable of breaking windows, &c. whilſt the valves and leathern pipes of the engine have ſufficient water way to ſupply the jet in its greateſt velocity. Leather pipe of conſiderable length may be ſcrewed at one end to the noſel of the engine, and furniſhed at the other end with a wooden or braſs pipe for guiding the water into the inner apartments of houſes, &c. Between the pyramidal box L and the fore-end of the engine, there is a ſtrong iron bar O, lying in an horizontal poſition over the middle of the ciſtern, and playing in braſſes ſupported by two wooden ſtands; one of which, P, is placed between the two fore-ſtands of the upper rails, and the other is hid in the incloſure over the hind part. Upon proper ſquares of this bar are fitted, one near each end, two ſtrong croſs bars, which take hold of the long wooden cylindrical handles, by means of which the engine is worked; and the handles by which they are aſſiſted are ſuſpended at each end by chains in the form of a watch chain, and receive their motion jointly with the handles that are on the ſame ſide, by means of two circular ſectors of iron faſtened together, and fixed upon proper ſquares of the middle horizontal bar; the two fore-ones may be ſeen at Q; the two hind ones, repreſented on a larger ſcale in *fig.* 4. differ from the former only in thickneſs; for the fore-ſectors are made to carry only one chain each, faſtened by one end to their upper part, and by the lower end to the treddles; whereas the pair of the two hind ſectors is wide enough to carry two chains each; one for faſtening like thoſe of the fore ones for the motion of the treddles; and the other two chains are faſtened by their lower ends to the lower part of theſe ſectors, and by their upper ends to the top of the piſton bars, in order to give them motion. See *fig.* 4. in which the hind ſectors and their apparatus are repreſented, as they would appear to a perſon, ſtanding between the two fore-wheels, and looking at the hind part of the engine. The ſquare over the letter A is the ſection of the middle bar, on which, right over the two barrels, are fixed the two ſectors b C A and D E A forged together. E G H K and *f g h k* are the two piſton rods; and the openings between the letters G, H, and *g*, *h*, are the ſpaces through which the hind parts of the two treddles paſs. L and M repreſent two ſtrong ſtuds riveted on the other ſide of the bars on which they are placed; and to each of theſe is faſtened a chain like a watch chain, fixed by their upper ends to the upper extremities D and B of the iron ſectors by which they are drawn up and down alternately. Theſe ſectors give alſo an alternate motion up and down to the piſton-rods, by means of two other chains left white in the figure, in order to diſtinguiſh them from the others: theſe are faſtened by their lower ends to the lower extremities of the ſectors E and C, and their upper ends terminating in a male ſcrew, are made right to the piſton rods at F and *f*, by two nuts. The ſhape of the piſton-rods, and the uſe and function of the chains that give them motion, are ſo contrived, that the vertical axis of the piſtons is exactly in the middle of the breadth of the perpendicular part of the chain, and of the upper part of the piſton rods taken together. P Q repreſents one of the two croſs bars through the ends of which paſs the long handles, to which the men apply their hands when they work the engine; theſe croſs bars are fixed on the middle bar at ſome diſtance from the ſectors.

The other parts of this uſeful engine may be underſtood by the help of *fig.* 5. which repreſents a vertical ſection taken through the middle line of the hind part of the engine, as alſo the ſection of the air veſſel, and that of one of the barrels, and likewiſe the profiles of the hind ſectors, and of ſeveral other parts. A B is the ſection of the bottom of the ciſtern, and C that of the hindmoſt axle-tree. D E is the vertical ſection of a ſtrong piece of caſt braſs or hard metal, (to work as to have a hollow in it, repreſented by the white part, and fixed to the bottom of the ciſtern: this reaches from the opening D through the cock W, and afterwards divides itſelf into two branches, ſo as to open under the two barrels; one of theſe branches is examined in the figure, and the other is exactly behind this. Through this channel, which may be called the ſucking-piece, water is conveyed to the pumps by the preſſure of the atmoſphere, either from the ciſtern itſelf, or from any place at a diſtance, by means of a leathern pipe F, *fig.* 3. which ſcrews on to the ſucking-piece at D, *fig.* 5. under the hind trough Z, the grate of which is repreſented by the horizontal ſtrokes. F G repreſents the vertical ſection of another piece of caſt braſs or hard metal that may be called the communication-piece, having two hollows for conveying the water from under the two piſtons to the two openings of the ſtanch of the air-veſſel: one of theſe hollows appears in the figure, the other lies exactly behind this, though not in a parallel direction. Between the ſection of the ſucking-piece D E and that of the communication-piece F G may be obſerved the ſection of one of the plates of leather, which makes all tight, and forms one of the two ſucking valves, of which there is another juſt behind this under the other barrel. R S T is the ſection of the copper air-veſſel, and T V that of the conduit-pipe; this veſſel is ſcrewed on to the hind part of the communication piece, and at top is faſtened by a collar of iron to a croſs piece of timber. Between the ſtanch of the air-veſſel and the communication-pipe may be obſerved the ſection of one of the plates of leather, making all tight, and ſcrewing one of the two forcing valves, of which there is another juſt behind this, exactly over the other opening of the communication from the air-veſſel. Theſe valves are loaded with a lump of caſt iron or lead, having a tail or tear let through the ſtap of the valve and croſs-pinned under it; and it is to be obſerved, that, though both the valves are repreſented open in the figure, they are never both open at the ſame time; for when the engine is not at work they are cloſed down by the weights on their upper ſurfaces; and when the engine works, two are ſhut, and the other two are open alternately by the motion of the piſtons and the action of the atmoſphere, together with the re-action of the air contained in the air-veſſel. H I is the ſection of one of the barrels of the two pumps which are both ſucking and forcing, as is evident from the poſition of the valves and the ſtructure of the piſtons, each of which is compoſed of two iron plates of two wooden trenchers, and of two flat pieces of leather turning one up and the other down. L K repreſents one of the piſton rods edge-wiſe, behind which is one of the

chains,

chains, the top screw of which, K, can only be seen. M is the end of the middle bar, and N a section of the hindmost of the two middle stands which support the middle bar. O represents the end of the profile of one of the treddles, passing through the rectangular holes of the pulley-rods, as in *fig.* 2. The weight on these treddles brings them and the pulley-rods down alternately, and they are raised up again by help of the other set of chains, one of which may be seen edge-wise in this figure, placed on the sole of one of the sectors, &c. See *fig.* 4. P Q is part of the cross bars which carry the handles, seen edge-wise; and X Y represents an iron handle, by the help of which the cock W may be placed in the several situations requisite for the use of the engine. The mechanism of the cock W may be understood by *fig.* 6, 7, and 8, which represent the horizontal section of it in three different situations. It has three holes that are left white in these figures. In *fig.* 6. the position of the cock is represented when the handle X Y or K is in a direction parallel to D E, or to the middle bar, as in *fig.* 5 and *fig.* 3. In this position, the water supplied by the sucking-pipe enters at D, and proceeds directly through the cock W to the valve under the two pistons; and there is now no communication from the barrels with the cavity of the cistern. In *fig.* 7. we have the position of the cock when the handle X Y is turned one quarter of a revolution towards the eye from the last mentioned situation, in which case there is no communication from the barrels with the outer extremity of the sucking-piece, but the water poured into the fore and hind trough, and passing from thence into the cavity of the cistern, enters the cock sideways at W, and turning at right angles through the cock towards E, proceeds to the barrels of the pumps. *Fig.* 8. represents the cock W when the handle is placed diametrically opposite to its last situation, in which case there is no communication from the under-side of the barrels with the cavity of the cistern or the outward end of the sucking-piece; but this situation affords a communication from the cavity of the cistern with the outside of the engine, and the water left in the cavity of the cistern may by this means be emptied when the engine has done working. These engines are made of five or six different sizes. See DeAguliers's Course of Exper. Philos. vol. ii. p. 508—518.

The principles on which this engine acts, so as to produce a command stream are obvious; the water being driven into the air-vessel, as in the operation of common sucking and forcing pumps, will compress the air contained in it, and proportionably increase its spring, since the force of the air's spring will always be inversely as the space which it possesses: therefore, when the air-vessel is half filled with water, the spring of the included air, which is its original state considered as the pressure of the atmosphere, being now compressed into half the space, will be equal to twice the pressure of the atmosphere; and by the action on the subsequent water will cause it to rise through the conduit pipe, and to play a jet of 32 or 33 feet high, abating the effect of friction. When the air-vessel is two-thirds full of water, the space which the air occupies is only one-third of its first space; therefore, its spring being three times as great as that of the common air, will project the water with twice the force of the atmosphere, or to the height of 64 or 66 feet. In the same manner, when the air-vessel is three-fourths full of water, the air will be compressed into one-fourth of its original space, and cause the water to ascend in air with the force of three atmospheres, or to the height of 96 or 99 feet, &c. as in the following table:

Height of Height of the Proportion of Height to which the water compressed in the air's spring the water will rise			
1	1	2	33 feet

See Martin's Philos. Brit. vol. ii. p. 69, &c.

FIRE-*engine* is also a name frequently given to a machine for raising water by steam, more properly called STEAM-*engine*.

FIRE, *everlasting*, in *Pagan Theology*, is a kind of reputed sacred *fire* worshipped by the GAVERS or GUEBRES in Persia. Dr. Mounter, formerly physician to the Czarina's army, has given the following account of it: this perpetual *fire* rises out of the ground in the peninsula of Abscheron, about twenty miles from Baku, and three miles from the Caspian shore. The ground is rocky, over which is a shallow covering of earth. If a little of the surface be scraped off, and *fire* be applied to the hollow, it catches flame immediately, and burns without interruption, and almost without consumption; nor is it ever extinguished unless some cold earth be thrown over it, by which it is easily put out. There is a spot of ground, about two English miles in extent, which has this property, where the earth continually burns; but the most remarkable part of it is a hole about four feet deep, and fourteen in diameter. This *fire* is worshipped, and is said to have burnt many thousand years. The cracks in the walls of the caravanseras, inhabited by the religious, are covered with flame, if a candle be held to them; and when there is occasion for a small light, no more is necessary than to stick one end of a piece of reed in the ground, and apply a lighted candle to the other; a flame will kindle at the top of the reed, and burn till it is extinguished by covering it. They burn flames into lime, by filling a hole in the ground with a heap of them, and bringing a lighted candle to the hole, upon which the *fire* kindles, and in about three days burns the flames sufficiently. The flame yielded by this *fire* has neither smoke nor smell. This sacred and natural phenomenon is nothing more than an inflammable vapour, which issues in great quantity out of the ground in this place, and is supplied by the naphtha with which the adjacent country abounds. Philos. Trans. vol. xlv. for 1748, p. 296.

FIRE, *extinguishing of*. The world has long been in an opinion, that a more ready way than that in general use might be found for *extinguishing* fires in buildings; and it has been generally attempted upon the doctrine of explosion. Zachary Greyl was the first person who put this plan into execution with any tolerable degree of success. He contrived certain engines, easily manageable, which he proved before some persons of the first rank to be of sufficient efficacy, and offered to discover the secret by which they were contrived for a large premium given either from the crown, or raised by a subscription of private persons. But this scheme meeting with no better success than things of this nature usually do, he died without making this discovery. Two years after this, the people who had his papers found the method; and it was shewn before the king of Poland and a great concourse of nobility at Dresden, and the secret purchased at a very considerable price. After this the same person carried the invention to Paris and many other places, and practised it every where with success. The secret was this: a wooden vessel was provided holding a very considerable quantity of water; in the centre of this there was fixed a case made of iron plates, and filled with gun-powder; from this vessel to the head of the larger vessel containing the water, there proceeded a tube or pipe, which might convey the *fire* very readily through the water to the gun-powder contained in the inner vessel. This tube was filled with a preparation easily taking *fire*, and quickly burning away; and the manner of using the engine was to convey it into the room or building where the *fire* was, with the powder in the tube lighted. The consequence of this was, that the powder in the inner case soon took *fire*, and, with a great explosion, burst the vessel to pieces, and dispersed the water every way; then was the *fire* put out in an instant, though the room was flaming before in all parts at once. The advantage of this invention was, that at a small expence, and with the help of a few people, a *fire* in its beginning might be extinguished; but the thing was not so general as at was at first expected that it would prove; for though of certain efficacy in a chamber or close building where *fire* had but newly begun; yet when the mischief had increased so far, that the house was fallen in, or the top open, the machine had no effect. This was the contrivance first discovered by Greyl, and from which our chemist Godfrey took the hint of the machine, which he called the WATER-*bomb*, and would fain have brought into use in England. Act. Erudit. ann. 1721. p. 183. Dr. Hales proposes to check the progress of *fires* by covering the floors of the adjoining houses with earth. The proposal is founded on an experiment which he made with a fir board, half an inch thick, part of which he covered with an inch depth of damp garden mould; and then lighted a *fire* on the surface of the mould; though the *fire* was kept up by blowing, it was two hours before the board was burnt through, and the earth prevented it from flaming. The thicker the earth is laid on the floors, the better, however, Dr. Hales apprehends, that the depth of an inch will generally be sufficient; and he recommends to lay a deeper covering on the flats, because the *fire* commonly ascends by them with the greatest velocity. Philos. Trans. vol. xlv. for 1748, p. 277.

Mr. Hartley made several trials in the years 1775 and 1776, in order to evince the efficacy of a method which he had invented for restraining the spread of *fire* in buildings.

ings. For this purpose thin iron plates are nail'd to the tops of the joists, &c. the edges of the sides and ends being lapped over, folded together, and hammered close. Partitions, stairs, and floors, may be defended in the same manner; and places applied to one side have been found sufficient. The plates are so thin as not to prevent the floor from being nailed in the joists in the same manner as if this preventative were not used: they are kept from rust by being painted or varnished with oil and turpentine. The expence of this addition, when extended through a whole building, is estimated at about *five per cent.* Mr. Hartley has a patent for this invention, and parliament has voted a sum of money towards defraying the expence of his numerous experiments. 14 Geo. III. cap. 87.

The same preservative may also be applied to ships, furniture, &c.

Lord Mahon has also discovered and published a very simple and effectual method of securing every kind of building against all danger of *fire*. This method he has divided into three parts, viz. under-flooring, extra-lathing, and inter-flooring. The method of under-flooring is either single or double: in single under-flooring, a common strong lath of oak or fir, about one-fourth of an inch thick, should be nailed against each side of every joist, and of every main timber, supporting the floor which is to be secured. Other similar laths are then to be nailed along the whole length of the joists, with their ends butting against each other. The top of each of these laths or fillets ought to be at 1¼ inch below the top of the joists or timbers against which they are nailed; and they will thus form a sort of small ledge on each side of all the joists. These fillets are to be well bedded in a rough plaster, hereafter mentioned, when they are nailed on, so that there may be no interval between them and the joists; and the same plaster ought to be spread with a trowel upon the tops of all the fillets, and along the sides of that part of the joists which is between the top of the fillets and the upper edge of the joists. In order to fill up the intervals between the joists that support the floor, short pieces of common laths, whose length is equal to the width of these intervals, should be laid in the contrary direction to the joists, and close together in a row, so as to touch one another; their ends must rest upon the fillets, and they ought to be well bedded in the rough plaster, but are not to be fastened with nails. They must then be covered with one thin coat of the rough plaster, which is to be spread even them to the level of the tops of the joists; and in a day or two this plaster should be trowelled over, close to the sides of the joists, without covering the tops of the joists with it.

In the method of double-flooring, the fillets and short pieces of laths are applied in the manner already described; but the coat of rough plaster ought to be little more than half as thick as that in the former method. Whilst this rough plaster is laid on, some more of the short pieces of laths, above mentioned, must be laid in the intervals between the joists upon the first coat, and be slipped deeper in. They should be laid as close as possible to each other, and in the same direction with the first layer of short laths. Over this second layer of short laths there must be spread another coat of rough plaster, which should be trowelled level with the tops of the joists, without rising above them. The rough plaster may be made of coarse lime and hair; or, instead of hair, hay chopped to about three inches in length may be substituted with advantage. One measure of common rough sand, two measures of slacked lime, and three measures of chopped hay, will form in general a very good proportion, when sufficiently beat up together in the manner of common mortar. The hay should be put in after the two other ingredients are well beat up together with water. This plaster should be made still; and when the flooring boards are required to be laid down very soon, a fourth or fifth part of quick-lime in powder, formed by dropping a small quantity of water on the lime-stone a little while before it is used, and well mixed with the rough plaster, will cause it to dry very fast. If any cracks appear in the rough plaster work, near the joists, when it is thoroughly dry, they ought to be closed by washing them over with a brush wet with mortar made: this wash may be prepared by putting two measures of quick-lime, and one of common sand in a pail, and stirring the mixture with water till the water becomes of the consistence of a thin jelly.

Before the flooring boards are laid, a small quantity of very dry common sand should be strewed over the plaster-work, and struck smooth with an hollow rule, moved in the direction of the joists, so that it may be rounding between each pair of joists. The plaster-work and sand should be perfectly dry before the boards are laid for fear of the dry rot. The method of under-flooring may be successfully applied to a wooden flair-case, but no sand is to be laid upon the rough plaster-work. The method of extra-lathing may be applied to ceiling joists, to sloping roofs, and to wooden partitions.

The third method, which is that of inter-securing, is very similar to that of under-flooring; but no sand is afterwards to be laid upon it. Inter-securing is applicable to the same parts of a building as the method of extra-lathing, but it is seldom necessary.

Lord Mahon has made several experiments in order to demonstrate the efficacy of these methods. In most houses, it is only necessary to secure the floors, and the extra-expence of under-flooring, including all materials, is only about nine pence per square yard; and with the use of quick-lime a little more. The extra expence of the method of extra-lathing is no more than six pence per square yard, for the timber-work all round partitions; but for the ceiling, about nine pence per square yard. But in most houses no extra-lathing is necessary. Philos. Trans. vol. lxvii. for 1777, part ii. art 40. p. 881, &c.

FIRE-*office*, in *Book-keeping*. See POSTHUMUS *entries*.

FIRE-*fly*, in the *History of Insects*. Among the flies of Guiana, there are two species of *fire-flies*. The largest is more than one inch in length, having a very large head, connected with the body by a joint of a particular structure, with which, at some times, it makes a loud knock, especially when laid on its back. This fly has two feelers, or horns, two wings, and six legs. Under its belly is a circular patch, which, in the dark, shines like a candle; and on each side of the head, near the eyes, is a prominent, globular, luminous body, in size about one-third larger than a mustard seed. Each of these bodies is like a rising star, emitting a bright, and not small light; since two or three of these animals, put into a glass vessel, afford light sufficient to read without difficulty, when placed close to a book. When the fly is dead, these bodies will still afford considerable light, though less vivid than before; and if bruised, and rubbed over the hands and face, they become luminous in the dark, like a board covered with phosphorus. They have a reddish brown colour, and live in rotten trees in the day, but are always abroad in the night. The other kind are not more than half as large as the former, and their light proceeds from under their wings, and is seen only when they are elevated, like sparks of *fire*, appearing and disappearing every second. Of these the air is full in the night, though they are never seen in the day. They are common, not only in the southern, but northern parts of America, during the summer.

FIRE-*lock*, or FUSIL, a small gun, which fires with a flint and steel. It is distinguished from an old musket or match-lock, which was fired with a match. The *fire-lock* is now in common use with the European armies, and carried by the foot soldiers. It is three feet eight inches in the barrel; and, including the lock, four feet eight inches, and carries a leaden bullet, of which twenty-nine make 1lb. In answer to the fifty-five hundredths of an inch, and three quarters, one and a fifteenth part of the *fire-locks* were made use of by the army, when marble locks were diffused; but the time of their invention is uncertain.

For the use of the *fire-lock*, *See* EXERCISE.

FIRE-*master*, in our *Train of Artillery*, is an officer who gives the directions, and the proportions of the ingredients for all the compositions of *fire-works* whether for service in war, or for rejoicings and recreations. He has a mate to assist him.

His orders are given to the *fire*-workers and bombardiers, who are obliged to execute them.

FIRE-*office*, an office of insurance from *fire*. See INSURANCE.

FIRE-*proof*. See CHINESE.

FIRE-*philosophers*, or *Philosophi per ignem*, a sanatical sect of philosophers who appeared towards the close of the fifteenth century, and made a figure in almost all the countries of Europe. The distinguishing tenet from which they derived this appellation was, that the intimate essences of natural things were only to be known by the trying effects of *fire*, directed in a chymical process. They were also called *Theosophists*, from their declaiming against human reason as a dangerous and deceitful guide, and representing a divine and supernatural illumination as the only means of arriving at truth; they were likewise denominated *Paracelsists*, from the name of Paracelsus, the eminent physician and chymist, who was the chief ornament and leader of this extraordinary sect. It was patronized in England by M. Robert Flood or Fludd, who endeavoured to illustrate the philosophy of Paracelsus in a great number of treatises; in France, it was zealously propagated by Rivier; in Denmark, by Severinus; in Germany, by Kunrath, an eminent physician of Dresden; and in other countries by warm and forceful votaries, who affected a thinking air of piety and devotion,

devotion, and propoſed to themſelves no other end than the advancement of the Divine glory, and the reſtoration of peace and concord in a divided church; accordingly they were joined by ſeveral perſons eminent for their piety, and diſtinguiſhed by their zeal for the advancement of true religion. One of the moſt celebrated of theſe was Daniel Hoffman, profeſſor of divinity in the univerſity of Helmſtadt, who, availing himſelf of ſome unguarded paſſages in the writings of Luther, extravagantly maintained, that philoſophy was the mortal enemy of religion; that truth was diviſible into two branches, the philoſophical and theological; and that what was true in philoſophy was falſe in theology. Hoffman was afterwards obliged, by the interpoſition of Henry Julius, duke of Brunſwick, to retract his invectives againſt philoſophy, and to acknowledge in the moſt open manner the harmony and union of ſound philoſophy with true and genuine theology. Moſheim's Eccl. Hiſt. by Maclean, vol. iv. p. 17, 18. 8vo. edit. 1768.

FIRE-*places* are contrivances for communicating heat to rooms, and alſo for anſwering various purpoſes of art and manufacture. For the latter kind, ſee FURNACE, and STOVE.

The principal objects with regard to the former are leſſening the charge of fuel and augmenting the benefit of *fire*. The general properties of air and *fire*, on which their conſtruction chiefly depends, are the following, viz. that air is rarefied by heat, and condenſed by cold; i. e. the ſame quantity of air takes up more ſpace when warm than when cold: air rarefied and expanded by heat is ſpecifically lighter than it was before, and will riſe to other air of greater denſity; ſo that a *fire* being made in any CHIMNEY, the air over the *fire* is rarefied by the heat, becomes lighter, and immediately riſes in the funnel, and goes out; the other air in the room, flowing towards the chimney, ſupplies its place, is rarefied in its turn, and riſes likewiſe; and the place of the air thus carried out of the room, is ſupplied by freſh air coming in through doors and windows, or, if they be ſhut, through every crevice with violence; or if the avenues to the room be ſo cloſed up, that no freſh ſupply of air can be obtained, the current up the funnel muſt flag; and the ſmoke, no longer driven up, float about in the room. Common *fire* throws out light, heat, and ſmoke; the light and heat move in right lines with great ſwiftneſs, but the ſmoke is but juſt ſeparated from the fuel, and moves only as it is carried off by the ſtream of rarefied air; and without a continual acceſſion of air, will remain crowded about the *fire*, and ſtifle it. Heat may be ſeparated from the ſmoke and light by means of a plate of iron; and the greateſt ſenſible heat is directly over the *fire*, where, beſides the rays of heat ſhot upwards, there is a continual riſing ſtream of hot air, heated by thoſe rays that are ſhot round on every ſide.

The *fire-places* moſt in uſe are, 1. The large open *fire-places*, that were commonly uſed in former times, and are ſtill continued in the country, and in kitchens. Theſe require a large funnel, conſume a great quantity of fuel, generally ſmoke, if the door be not left open, and contribute little to warm a room. Their ſpaciouſneſs is their greateſt convenience.

2. Inſtead of theſe old-faſhioned chimnies, the modern *fire-places*, eſpecially in towns, have been conſtructed with low breaſts and hearths, narrowed by jambs. *Fire-places* of this contracted form will keep rooms generally free from ſmoke; but the funnel requires a conſiderable quantity of air, which ruſhes in at every crevice, ſo as to render the ſituation of perſons continually expoſed to it uncomfortable, and dangerous. Many of the diſeaſes proceeding from colds may be aſcribed to ſtrong drawing chimnies, whereby, in ſevere weather, perſons are ſcorched before, while they are froze behind. Theſe *fire-places* are of little uſe in warming a room; becauſe the air round them, which is warmed by the direct rays of the *fire*, does not continue in the room, but is continually collected into the chimney by the current of cold air coming behind it, and is preſently carried off. Beſides, the greateſt part of the *fire* is loſt, being abſorbed by the back jambs and hearth, which are ſo dark and porous as to reflect very little, and the upright heat flies directly up the chimney. To remedy this inconvenience the Sieur Gauger, in his book entitled La Mechanique de Feu, publiſhed in 1709, and ſince tranſlated by Dr. Deſaguliers (ſee CHIMNEY), propoſed ſeven different conſtructions of. 3. A third ſort of chimnies, in which there are hollow cavities made by iron plates in the back, jambs, and hearth, through which plates the heat paſſing, warms the air in thoſe cavities, which is continually coming into the room freſh and warm. This conſtruction had many obvious advantages; but the expence and difficulty attending it diſcouraged the propagation of the invention. However, the upright heat was almoſt wholly loſt in theſe as in the common chimnies. 4. Another kind of *fire-place* is the Holland iron ſtove, with a flue proceeding from the top, and a ſmall iron door opening into the room. Theſe ſerve to warm a room, ſave fuel, and produce a conſtant change of air. But the *fire* is not ſeen, and little uſe can be made of it beſides that of warming the room. It is therefore rarely uſed in England, except in ſome work-ſhops. 5. The German ſtove is compoſed of five iron plates ſcrewed together, and fixed ſo as that the fuel may be put into it from another room, or from the outſide of the houſe. It is a kind of oven reverſed, its mouth being without, and body within the room that is to be warmed by it. This ſtove warms a room with little fuel, and is attended with no danger from the irruption of cold air; but the *fire* is not ſeen, and there is no change of air in the room heated by it. For an account of the Chineſe ſtove, ſee KANG.

6. Another kind of convenience for warming rooms is a charcoal *fire* kindled in pots and chaffing diſhes. This is chiefly uſed in the ſhops of handicraftſmen. But the ſulphureous fumes ariſing from the coals render this mode of giving heat diſagreeable and dangerous, and in a cloſe room ſometimes fatal.

The ingenious Dr. Franklin, whoſe name we have had frequent occaſion of recording in this work, having recounted the inconveniences and advantages of *fire-places* in common uſe, propoſes a new contrivance for this purpoſe, called the Penſylvania *fire place*. 1. This machine conſiſts of a bottom-plate or hearth-piece [*ſee Tab. Miſcellany, fig.* 6.] with a ſtiling moulding before for a feuder, two perforated ears F, G, for receiving two ſcrew-rods; a long air-hole, *ab*, through which the outward air paſſes into an air-box; and three ſmoke-holes repreſented by dark ſquares in BC, through which the ſmoke deſcends and paſſes away, beſides double ledges for receiving between them the lower edges of the other plates. 2. A back plate without holes, and furniſhed with a pair of ledges to receive, 3. The two ſide-plates, each of which has a pair of ledges to receive the ſide-edges of the front plate, with a ſhoulder on which it reſts; two pair of ledges to receive the ſide-edges of the two middle plates which form the air-box, and an oblong air-hole near the top, through which the air warmed in the box is diſcharged into the room, and a wing or bracket, as H, and a ſmall hole, as B, for the axis of the regiſter to turn in. See *fig.* 7. which repreſents one of theſe plates. 4. An air-box, compoſed of the two middle plates DE and FG, *fig.* 8. and 9. The firſt has five thin ledges or partitions caſt on it, the edges of which are received into ſo many pair of ledges caſt in the other: the tops of all the cavities formed by theſe thin deep ledges are alſo covered by a ledge of the ſame form and depth caſt with them; ſo that when the plates are put together, and the joints luted, there is no communication between the air-box and the ſmoke. In the winding paſſages of this box, freſh air is warmed as it paſſes into the room. 5. A front plate, which is arched on the under ſide, and ornamented with foliages, &c. 6. A top plate, with a pair of ears M, N, *fig.* 10.) anſwerable to thoſe in the bottom plate, and perforated for the ſame purpoſe. It has alſo a pair of ledges running round the under ſide to receive the top edges of the front, back, and ſide plates. The air-box does not reach up to the top-plate by 2½ inches.

All theſe plates are of caſt iron; and when they are all in their proper places, they are bound firmly together by a pair of ſlender rods of wrought iron with ſcrews, and the machine appears as in *fig.* 10. There are alſo two thin plates of wrought iron, viz. 7. The ſhutter, which is of ſuch a length and breadth as to cloſe well the opening of the *fire-place*, and ſerving to blow up the *fire*, and to ſecure it in the night. It is raiſed or depreſſed by means of two braſs knobs, and ſlides in a groove left between the foremoſt ledge of the ſide plates and the face of the front place. 8. The regiſter, which is placed between the back plate and air-box, and furniſhed with a key; ſo that it may be turned on its axis and made to lie in any poſition between level and upright. The operation of this machine, and the method of fixing it may be underſtood by obſerving the profile of the chimney and *fire-place* in *fig.* 11. M is the mantle-piece or breaſt of the chimney; C the funnel; B the falſe back, made of brick-work in the chimney, four inches or more from the true back, from the top of which a cloſing is to be made over to the breaſt of the chimney, that no air may paſs into the chimney except that which goes under the falſe back, and up behind it; E the true back of the chimney; T the top of the *fire-place*; F the front of it; A the place where the *fire* is made; D the air-box; K the hole in the ſide plate, through which the warmed air is diſcharged out of the

box into the room; H the hollow, formed by removing ſome bricks from the hearth under the bottom plate filled with freſh air, entering at the paſſage I, and aſcending into the air-box through the air-hole in the bottom plate near G, the partition in the hollow, deſigned to keep the air and ſmoke apart; P the paſſage under the falſe back, and part of the hearth for the ſmoke; and the arrows in the figure ſhew the courſe of the ſmoke. The *fire* being made at A, the flame and ſmoke will aſcend, ſtrike the top T, and give it a conſiderable heat; the ſmoke will turn over the *fire*-back, and deſcend between it and the back plate to the holes near G in the bottom plate, heating in its paſſage all the plates of the machine; it will then proceed under and behind the falſe back, and riſe into the chimney. The air of the room contiguous to the ſeveral plates, and warmed by them, becomes ſpecifically lighter than the other air in the room, and is obliged to riſe; but, being prevented by the cloſure over the *fire*-place from going up the chimney, is forced out into the room, and riſing by the mantle-piece to the ceiling, is again driven down gradually by the ſtream of newly-warmed air that follows; and thus the whole room becomes in a little time equally warmed. The air, alſo, warmed under the bottom plate and in the air-box, riſes and comes out of the holes in the ſide plates, and thus warming and continually changing the air of the room. In the cloſing of the chimney a ſquare opening for a trap-door ſhould be left open for the ſweeper to go up: the door may be made of ſlate or tin, and ſo placed, that by turning up againſt the back of the chimney when open, it cloſes the vacancy behind the falſe back, and ſhoots the ſoot that falls in ſweeping out upon the hearth. It will alſo be convenient to have a ſmall hole about five or ſix inches ſquare, cut near the ceiling through into the funnel, and provided with a ſhutter, by occaſionally opening which, the heated air of the room and ſmoke of tobacco, &c. may be carried off without incommoding the company. For a farther account of the manner of uſing this *fire-place*, the advantages attending it, anſwers to objections, and directions to the brick-layer in fixing it, the curious reader may conſult Franklin's Letters and Papers on Philoſophical Subjects, p. 284—318. edit. 1769.

FIRE-*pots*, in the *Military Art*, are ſmall earthen pots into which is put a grenade, filled with fine powder till the grenade be covered; and then the pot is covered with a piece of parchment, and two pieces of match laid acroſs and lighted. This pot being thrown where it is deſigned to do execution, breaks and *fires* the powder, and thereby *fires* the powder in the grenade, which ought to have no fuze, that its operation may be the quicker.

FIRE, *retreat* or *reſort*, is a *fire* from the artillery and ſmall arms directed in a line parallel to the horizon, or to thoſe parts of the works of a place that are defended.

FIRE, *running*, is when a rank or ranks of men drawn up *fire* one after another; or when the lines of an army are drawn out to *fire* on account of a victory; in which caſe each ſquadron or battalion takes it from that on its right, from the right of the firſt line to the left, and from the left to the right of the ſecond line, &c.

FIRE-*ſhips*, in the Navy, veſſels charged with combuſtible materials or artificial *fire*-works; which having the wind of an enemy's ſhip, grapple her, and ſet her on *fire*.

It is obſerved by Anderſon, in his Hiſtory of Commerce, vol. i. p. 432. that ſome Engliſh veſſels, filled with combuſtible matter, and ſent among the Spaniſh ſhips compoſing the Invincible Armada in 1588, are ſaid to have given riſe to the terrible invention of *fire-ſhips*. However, Livy informs us, that the Rhodians had invented a kind of *fire*-ſhips which were uſed in junction with the Roman fleet in their engagement with the Syrians in the year before Chriſt 190: cauldrons of combuſtible and burning materials were hung out at their prows, ſo that none of the enemies ſhips durſt approach them: theſe fell on the enemies gallies, ſtruck their beaks into them, and at the ſame time ſet them on *fire*. Liv. lib. xxxvii. cap. 30. tom. iii. p. 322. Ed. Crevier.

There is nothing peculiar in the conſtruction of a modern *fire-ſhip*, except the apparatus, by which the *fire* is inſtantly conveyed from one part to another, and from thence to the enemy: for this purpoſe the *fire*-room, in which the combuſtibles are incloſed, is built between decks, and extends from the bulk-head at the forecaſtle to a bulk-head raiſed behind the main-maſt. The train incloſed in this apartment is contained in a number of wooden troughs which interſect each other in different parts of the ſhip's length, being ſupported at proper diſtances by croſs-pieces and ſtanchions. On each ſide of the ſhip are cut out ſix or ſeven port-holes, in ſize about fifteen by eighteen inches, with their lips opening downward, and cloſe caulked up. Againſt each port is fixed an *iron*-CHAMBER, which, when the ſhip is fired, blows out the port-lid and lets out the flame. Under the main and fore-ſhrouds is fixed a wooden funnel, one end of which communicates with a FIRE-*barrel*, and deſigned to convey the flames to the ſhrouds. Between the funnels, called alſo *fire*-trunks, are two ſcuttles or ſmall holes in the upper deck, ſerving alſo to let out the flames. Both funnels and ſcuttles muſt be ſtopped with plugs, and have ſail-cloth or canvas nailed over them, to prevent any accident happening from above to the combuſtibles below. The port-holes, funnels, and ſcuttles, ſerve not only to communicate the flames to the outſide and upper works of the ſhip and her rigging, but likewiſe to open a paſſage for the inward air confined in the *fire*-room, ſo that it may expand itſelf without blowing up the decks. On each ſide of the bulk-head behind is cut a hole big enough to receive a trough of the ſame ſize as the others; leading troughs whoſe foremoſt ends communicate with other troughs within the *fire*-room, extend obliquely from theſe openings to ſally-ports cut through the ſhip's ſide: the decks and troughs are well covered with melted roſin. When either of the leading-troughs is fired, the flame is immediately conveyed to the oppoſite ſide of the ſhip, and both ſides burn together.

The cabbins of the lieutenant and maſter are behind the *fire*-room, one on the ſtarboard and the other on the larboard ſide. The captain's cabin is ſeparated from theſe by a bulk-head.

The ſtores for a *fire-ſhip* of 150 tons are 8 FIRE-*barrels*, 12 *iron*-CHAMBERS, 3½ priming compoſition barrels, 1 QUICK-*match* barrel, 30 dipped CURTAINS, 150 long REEDS ſingle dipped, 75 ſhort reeds ſingle dipped, 75 ſhort reeds double dipped, 200 bavins ſingle dipped, and 24 PORT-*fires*.

The quantity of compoſition for preparing the ſtores of a *fire-ſhip* is exhibited in the following table:

	petre. lb.	ſulph. lb.	corn pow. lb.	pitch. lb.	roſin. lb.	tall. lb.	tar. lb.	oil. pts.
For 8 barrels,	0	0	360	480	0	80	0	0
For 3½ ditto priming compoſition,	175	140	350	0	21	0	0	12
For the curtains, bavins, and reeds for the ſhip, and ſulphur for falling them,	0	200	0	350	175	50	25	0
Total.	175	340	1310	830	196	130	25	12

For reeds for the barrels, 160*lb.* being one-fifth of the whole of the laſt article.

When all the ſtores are provided, they are diſpoſed of in the following manner: four of the eight *fire*-barrels are placed under the four *fire*-trunks, and the other four between them, two on each ſide the *fire*-ſcuttles, where they are ſecurely cleated to the deck. The longeſt reeds are put into the fore and aft troughs, and tied down; the ſhorteſt reeds are laid in the troughs athwart, and tied down alſo: the bavins, dipped at one end, are tied faſt to the troughs over the reeds, and the curtains are nailed up to the beams in equal quantities on each ſide of the *fire*-room. The remainder of the reeds is placed in a poſition nearly upright at all the angles of every ſquare in the *fire*-room, and there tied down; and ſome of them are put round the *fire*-barrels and tied faſt. The priming compoſition is ſtrewed along all the troughs, and over the reeds and bavins; then lay the quick-match two or three ſtrands thick on the reeds, and about the *fire*-barrels and chambers, in order to communicate a general *fire* at once; let the plugs be taken out of the funnels and ſcuttles, the curtains covering the *fire*-barrels be cut and rolled back; and let the leading troughs be laid with four or five ſtrands of quick-match, and alſo the communication-trough, ſo that the *fire* may be communicated to the whole at once. Port-*fires*, which burn about twelve minutes, are frequently uſed for firing the ſhip in preference to matches. When two fleets commence an engagement, thoſe who have the care of the *fire-ſhips* prime and prepare their *fire*-works; and when they are ready for grappling, inform the admiral of it by a particular ſignal. Muſtler's Syſtem of Math. &c. vol. v. p. 99, &c. and Falconer's Mar. Dict.

FIRE-*ſtone* is a coarſe, harſh, duſty FREE-*ſtone*, of a moderately compact texture, of a pale greyiſh colour, nearly white, with a very ſlight greeniſh tinge. This ſtone is moderately hard and heavy, and ſlightly colours the hands: it is compoſed of a fine ſmall angular grit, cemented by an earthy ſparry matter, intermixed with numerous ſmall ſpangles of a ſilvery mica: it will not ſtrike *fire* with ſteel, and in the fire changes to a ſlight reddiſh hue. It is called alſo *Ryegate-ſtone*, from the place whence it is chiefly brought; it bears the *fire*, and is much uſed for chimneys, hearths, ovens, ſtoves, &c.

It does not bear the weather, and is therefore unfit for building.

FIRE-*water*, a name given to alcaheſt. See IGNIS *aquæ*.

FIRE,

FIRE, *wild*, is a kind of artificial or factitious *fire*, which burns even under water, and that with greater violence than out of it.

It is compoſed of ſulphur, naphtha, pitch, gum, and bitumen; and it is only extinguiſhable by vinegar, mixed with ſand and urine, or by covering it with raw hides.

Its motion or tendency is ſaid to be contrary to that of natural *fire*, and always following the direction in which it is thrown, whether it be downwards, ſidewiſe, or otherwiſe.

The French call it *Greek fire*, or *feu Gregeois*, becauſe firſt uſed by the Greeks about the year 660, as is obſerved by the Jeſuit Petavius, on the authority of Nicetas, Theophanes, Cedrenus, &c.

The inventor, according to the ſame Jeſuit, was an engineer of Heliopolis, in Syria, named Callinicus, who firſt applied it in the ſea-fight commanded by Conſtantine Pogonates againſt the Saracens, near Cyzicus, in the Helleſpont; and with ſuch effect, that he burnt the whole fleet therewith, wherein there were thirty thouſand men.

But others will have it of a much older date: and hold Marcus Graecchus the inventor; which opinion is ſupported by ſeveral paſſages, both in the Greek and Roman writers, which ſhew it to have been anciently uſed by both theſe nations in the wars. See Scaliger againſt Cardan.

Conſtantine's ſucceſſors uſed it on divers occaſions, with equal advantage, as himſelf: and what is remarkable enough is, that they were ſo happy as to keep the ſecret of the compoſition to themſelves; ſo that no other nation knew it in the year 960.

Hugh, king of Burgundy, demanding ſhips of the emperor Leo for the ſiege of Freſne, deſired likewiſe the Greek *fire*. Chorier, Hiſt. de Dauph.

F. Daniel gives us a good deſcription of the Greek *fire*, in his account of the ſiege of Damietta, under St. Louis. Every body, ſays that author, was aſtoniſhed with the Greek *fire* which the Turks then prepared; and the ſecret whereof is now loſt. They threw it out of a kind of mortar; and ſometimes ſhot it with an odd ſort of croſs bow, which was ſtrongly bent by means of a handle, or winch, of much greater force than the bare arm. That thrown with the mortar ſometimes appeared in the air of the ſize of a tun, with a long tail, and a noiſe like that of thunder. The French, by degrees, got the ſecret of extinguiſhing it; in which they ſucceeded ſeveral times.

FIRE-*works*, or *artificial* FIRES, are preparations made of gunpowder, ſulphur, and other inflammable and combuſtible ingredients, uſed on occaſion of public rejoicings, and other ſolemnities.

The principal of theſe are rockets, ſerpents, ſtars, hail, mines, bombs, garlands, ſetters, and other devices. See ROCKET, STAR, BOMB, &c.

The invention of *fire-works* is by M. Mahudel attributed to the Florentines and people of Sienna; who found out likewiſe the method of adding decorations to them of ſtatues, with *fire* iſſuing from their eyes and mouths.

The art of preparing and managing *fire-works* is called PYROTECHNY.

The making or ſelling of *fire-works*, or ſquibs, or throwing them about in any ſtreet, is, on account of the danger that may enſue to any thatched or timber buildings, declared to be a common nuſance, by 9 & 10 W. III. cap. 7. and puniſhed by a fine of 20*l*.

FIRE-*workers*, are ſubordinate officers to the *fire-maſters*, who command the bombardeers, and are ſecond lieutenants to the royal regiment of artillery.

Theſe receive the orders from the *fire-maſters*, and ſee that the bombardeers execute them.

FIRING, in the *Military Art*, denotes the diſcharge of the fire-arms; and its object is to do the utmoſt execution to the enemy.

The preſent method of *firing* by platoons is ſaid to have been invented by Guſtavus Adolphus, and firſt uſed about the year 1618; the reaſon commonly given for this method is, that a conſtant fire may be always kept up. There are three different ways of platoon *firing*; viz. ſtanding, advancing, and retreating. But previous to every kind of *firing*, each regiment or battalion muſt be told off in grand diviſions, ſubdiviſions, and platoons, excluſively of the grenadiers, which form two ſubdiviſions, or four platoons of themſelves. In *firing* ſtanding, either by diviſions or platoons, the firſt fire is from the diviſion or platoon on the right; the ſecond fire, from the left; the third, from the right again; and ſo on alternately, till the *firing* comes to the centre platoon, which is generally called the colour platoon, and does not fire, remaining as a reſerve for the colours. *Firing* advancing is performed in the ſame manner, with this addition, that before either diviſion or platoon fires, it advances three paces forward. *Firing* retreating varies from either of the former methods; for, before either diviſion or platoon fires, if they are marching from the enemy, it muſt go to the right about, and after *firing*, to the left about again, and continue the retreat as ſlow and orderly as poſſible.

In hedge-*firing* the men are drawn up two deep, and in that order both ranks are to fire ſtanding. Oblique *firing* is either to the right and left, or from the right and left to the centre, according to the ſituation of the object. The Pruſſians have a particular contrivance for this purpoſe; if they are to level to the right, the rear ranks of every platoon make two quick but ſmall paces to the left, and the body of each ſoldier turns one eighth of a circle, and *vice verſâ*. Parapet *firing* depends on the nature of the parapet over which the men are to fire, and alſo upon that of the attack made to poſſeſs it. This method of *firing* is ſometimes performed by ſingle ranks ſtepping on the banquette and *firing*; each man inſtantly handing his arms to the centre rank of the ſame file, and taking his back in the room of it: and the centre rank giving it to the rear to load, and forwarding the arms of the rear to the front rank; by which means the front rank men can fire ſix or ſeven rounds in a minute with exactneſs. Parapet *firing* may alſo be executed two deep, when the banquette is three feet broad, or in field works, where no banquettes are made. Square *firing* is performed by a regiment or body of men drawn up in a hollow ſquare, in which caſe each front is generally divided into four diviſions or *firings*, and the flanks of the ſquare, being the weakeſt part, are covered by four platoons of grenadiers. The firſt fire is from the right diviſion of each face; the ſecond from the left diviſion of each face, &c. and the grenadiers make the laſt fire. Street *firing* is practiſed in two ways; either by making the diviſion or platoon that has fired to wheel by half-rank to the right and left outwards from the centre, and to march in that order by half diviſions down the flanks on each ſide of the column, and to draw up in the rear, and go on with their priming and loading; or, to make the diviſion or platoon, after *firing*, to face to the right and left outwards from the centre, and one half rank to follow the other; and in that order to march in one centre file down on each ſide of the column into the rear, and there draw up as before.

FIRING-*iron*, in the *Manege*, is a piece of copper or iron, about a foot long, one end of which is made flat, and forged like a knife; the back of it being half an inch thick, and the fore edge about the fifth or ſixth part of this. When the farrier has made his *firing-iron* red-hot in his forge, he applies the thinneſt part to the horſes ſkin, and ſo gives the *fire* to the hams, or ſuch places as ſtand in need of it.

FIRKIN, an Engliſh meaſure of capacity, for things liquid; containing the fourth part of the barrel.

The *firkin of ale* contains eight gallons; and that of *beer*, nine; two *firkins* of beer make the kilderkin; two kilderkins the barrel; and two barrels the hogſhead.

The *firkins* of *ſoap* and *butter* are on the footing of the *firkins* of ale; viz. a gallon per *firkin* leſs than that of beer.

FIRLOT, a dry meaſure uſed in Scotland. The oat *firlot*, which contains 21½ pints of that country, is 10¼ inches in diameter both at top and bottom, being of a perfectly cylindrical form, and in depth 7½ inches. The wheat *firlot* contains about 2211 cubical inches, and the barley *firlot* 31 ſtandard pints; whereby it appears that the Scotch wheat *firlot* exceeds the Engliſh buſhel by 33 cubical inches.

FIRMAMENT, in the *Ancient Aſtronomy*, the eighth heaven, or ſphere; being that wherein the fixed ſtars were ſuppoſed to be placed.

It is called the *eighth*, with reſpect to the ſeven heavens or ſpheres of the planets, which it ſurrounds.

It is ſuppoſed to have two motions; a diurnal motion, given it by the primum mobile, from eaſt to weſt, about the poles of the ecliptic; and another oppoſite motion from weſt to eaſt; which laſt it finiſhes, according to Tycho, in 25412 years; according to Ptolemy, in 36000; and according to Copernicus, in 25800; in which time the fixed ſtars return to the ſame preciſe points wherein they were at the beginning. This period is commonly called Plato's year, or the great year. See PRECESSION *of the Equinox*.

In divers places of Scripture the word *firmament* is uſed for the middle region of the air. Many of the ancients allowed, with the moderns, that the *firmament* is a fluid matter; though they, who gave it the denomination of *firmament*, muſt have taken it for a ſolid one.

FIRMAN, in the Eaſt Indies, and particularly in the territories of the Great Mogul, is the paſſport, or permit, granted to foreign veſſels, to trade within their juriſdiction.

FIRMNESS, FIRMITAS, in *Philosophy*, denotes the consistence of a body; or that state, wherein its sensible parts cohere, or are united together, so that the motion of one part induces a motion of the rest. In which sense, *firmness* stands opposed to fluidity.

Some authors confound *firmness* with density; as thinking the same state or property of body implied by both; or at least, that *firmness* follows density; but this is a mistake. For mercury, the densest body in nature excepting gold, is yet one of the most fluid; and even gold itself, with all its density, when fused, wants *firmness*, or cohesion.

Many of the Cartesians, and others, hold *firmness* to consist in the mere quiet of the particles of the body, and their mutual immediate contact; arguing, that a separation of parts can only arise from some matter interposed between them, which is excluded by the notion of contiguity.

But the insufficiency of this hypothesis is evident: for mere simple rest has no force, either to act or resist; and consequently two particles only joined by rest and contiguity, would never cohere so as that a motion of the one should induce a motion of the other. This is obvious in the case of two grains of sand, which, however contiguous, and at rest, will never constitute a firm coherent body.

The *firmness* of bodies, then, depends on the connexion or cohesion of their particles. Now, the cause of cohesion, sir Isaac Newton, and his followers, hold to be an attractive force, inherent in bodies, which binds the small particles thereof together; exerting itself only at, or extremely near, the points of contact, and vanishing at greater distances.

The *firmness* of bodies, therefore, follows the laws of the COHESION of bodies.

Hence, *firmness* in all bodies must be as the surfaces and contact of the component parts: thus a body, whose parts are by their peculiar shapes capable of the greatest contacts, is most *firm*; and that, whose parts are capable of the least contact will be most soft.

In the former, the greatest requisite is to be as near to cubes as possible, and in the latter to spheres. And in the same manner are to be accounted for, not only all the intermediate degrees between the most *firm*, and the most soft bodies, but those different consistencies, which are distinguished by other names, as friable, tenacious, glutinous, and the like; for the greater are the solidities of the component parts of any body, in proportion to their surfaces, though that body, by the aptitude of the contacts, may be what we call *very hard*; yet it will be most friable or brittle. And where the surfaces of the component particles are much extended upon a small quantity of matter, the bodies they compose, though they may be light and soft, yet they will be tenacious or glutinous; for although the flexibility of their compounding parts admits of their easy changing of figure by any external force, yet by their touching one another in so many points, they are very difficultly separated.

The former is the case in crystallized salts, resins, and the like; the latter in turpentines, gums, and all of that sort.

FIRM-ORE, a kind of LEAD-ore.

FIRST *mover*, in the *Ancient Astronomy*. See PRIMUM *Mobile*.

FIRST-*fruits*, *Annates* or *Primitiæ*, the profits of a benefice for the first year after avoidance. See ANNATES and PRIMITIÆ.

The *first-fruits* were formerly estimated according to a rate or *value* made under the direction of pope Innocent IV. by Walter bishop of Norwich, in 38 Hen. III. and afterwards advanced in value by commission from pope Nicholas III. A. D. 1292, 20 Edw. I. which valuation of pope Nicholas is still preferred in the exchequer; and the tenths or *decimæ* were the tenth part of the annual profit of each living by the same valuation; claimed by the holy see on the authority of the precept recorded in Numb. xviii. 26. These papal usurpations were first introduced into this kingdom by Pandulph the pope's legate, during the reigns of king John and Henry III. in the see of Norwich, and afterwards attempted to be made universal by the popes Clement V. and John XXII. about the beginning of the fourteenth century. These claims were often opposed by the English parliament; but they continued till the Reformation in the reign of Henry VIII. at which period it was computed, that in the compass of 30 years 800,000 ducats had been sent to Rome for *first-fruits* only. This revenue was annexed to the crown by 26 Hen. VIII. cap. 3. confirmed by 1 Eliz. cap. 4. and a new *value beneficiorum* was then made, by which the clergy are at present rated. By these statutes all vicarages under ten pounds a year, and all rectories under ten marks, are discharged from the payment of *first-fruits*; and if the incumbent lives but half a year, he shall pay only one quarter of his *first-fruits*; if one whole year, half of them; if a year and a half, three quarters; and if two years, the whole. By stat. 27 Hen. VIII. cap. 8. no tenths are due to be paid for the first year; and by other statutes of queen Anne, in the fifth and sixth years of her reign, if a benefice be under fifty pounds per annum, clear yearly value, it shall be discharged of the payment of *first-fruits* and tenths. Queen Anne granted her royal charter, confirmed by stat. 2 Ann. cap. 11. whereby the whole revenue of *first-fruits* and tenths is vested in trustees for ever, to form a perpetual fund for the AUGMENTATION of poor livings, usually called queen Anne's bounty. Blackst. Comm. vol. i. p. 284, &c.

FIRST-*fruits*, *office of*, is kept in the Temple, under the direction of a remembrancer, receiver, and comptroller, and their deputies and clerks.

FIRUZINUS *color*, a term that frequently occurs in some of the old writers on gems, and has been mistaken by many to mean a ruby brown; and by others, black; but these are not colours to be sought after among the gems, and yet it is to those that this epithet is usually applied. We find it used for a blue kind of jasper by some authors, the same with the jaspis horeos of Pliny and Dioscorides, and by others for the sapphire, which some of the ancients, particularly Theophrastus, having called μέλας, that is, black in its deepest colour, authors have been led to suppose that this word stood for black; but as there are not, nor ever were any black sapphires, it is certain from this, as well as many other instances, that the ancients used this word, μέλας, for a deep blue, and in that sense *firuzinus color* does signify the same thing; it being the serinus color of the ancients, or what we call sky-colour, or a fine blue; such as the colour of the finest sapphires.

FISANELLE, in *Ornithology*, a name given by the Venetians to a water-fowl of the colymbus kind, called by authors the colymbus major, or great diver. Its general weight is about a pound, its beak is two fingers breadth long, and all its feathers are downy, soft, and very thick set together; its head and neck are brown, and its back is blackish; its sides and belly brown, and its breast of a silver white; it has no tail, and its wing-feathers are black and white; its feet are not webbed, but the toes are all widened by membranes. It is very common in the markets of Italy. Ray's Ornith. p. 256.

FISC, FISCUS, in the *Civil Law*, the treasury of a prince, or state; or that to which all things due to the public do fall.

The word is derived from the Greek φισκος, *a great basket*, used when they went to market.

By the civil law, none but a sovereign prince has a right to have a *fisc*, or public treasury. See ÆRARIUM.

FISCAL, something relating to the pecuniary interest of the king, the public, or a private person.

The emperor Adrian erected the office of *fiscal* advocate in the Roman empire.

FISCHERLIN, in *Ornithology*, a name given by many of the northern nations to a small species of the LARUS or GULL, called by Mr. Ray *larus piscator*, by Linnæus *larus minutus*, and in English, the lesser sea-swallow. It is smaller than the common black-bird. Its bill is yellow, tipt with black, its forehead and cheeks white; from the eyes to the bill is a black line. Its wings are long and grey, its feet short and yellow, its breast and belly are white, and of an exquisite gloss, the crown of its head black, and its back grey. They are very common on our coasts, and feed on small fish; but as they are delicate birds, and incapable of bearing the inclemency of the weather on our shores during winter, they quit their breeding places at its approach, and do not return till spring. Ray's Ornithology, p. 269.

FISGUM, a name used by some for the fish commonly called *usfgum*.

FISH, in *Natural History*, the fourth class of animals, including four orders, viz. *apodes*, *jugulares*, *thoracica*, and *abdominales*, which comprehend forty-seven genera, and four hundred species, in the Linnæan system; the characters of which are, that they have either a naked or scaly body, that they have no feet, and always have fins. According to the new Artedian system, *fish* in general are divided into five distinct orders. The generality of *fish* have the tail placed perpendicularly, but a few of them have it horizontally. Of those which have the tail perpendicular, some have the rays of the fins bony; and these either have the gills covered with a membrane, containing several bones, or they have no such membrane: of those which have this membrane, with the bones over the gills, some have the rays, though bony, yet not pungent; these are called the MALACOPTERYGII, or the soft-finned *fish*. Others have them with the rays

rays prickly; these are the ACANTHOPTERYGII, or prickly-finned *fish*. Those which have no bones in the membrane over the gills make only one genus, and are called the BRANCHIOSTEGI. The other kind, which have not bony, but cartilaginous rays in the fins, are called CHONDROPTERYGII. And finally, those *fish* which have the tail placed not perpendicularly, but horizontally, are called PLAGIURI.

Naturalists observe much wiſdom and deſign in the ſtructure of *fiſhes*, and their conformation to the element in which they are to reſide.

Their bodies are clothed and guarded in the beſt manner with ſcales, &c. ſuitable to their reſpective circumſtances, the dangers they are expoſed to, and the motion and buſineſs they are to perform.

The centre of gravity is placed in the fitteſt part of the body for ſwimming; and their ſhape is the moſt commodious for making way through the water, and moſt agreeable to geometrical rules.

They have ſeveral parts peculiar to themſelves; as fins, to balance and keep them upright. See FIN.

And an air-bladder, or *ſwim*, to enable them to riſe and ſink to any height and depth of water, at pleaſure.

They have alſo gills or bronchiæ, whereby they reſpire, as land animals do by the lungs.

The tail is the inſtrument of progreſſive motion, and ſerves to row them forward.

Their eyes are peculiarly formed to enable them to correſpond to all the convergencies and divergencies of rays, which their ariations of the watery medium, and the refractions thereof, may occaſion; in which reſpect they bear a near reſemblance to thoſe of birds.

Fiſh are diſtinguiſhed into *ſea*, or *ſalt-water fiſh*, *piſces marini*, as the whale, herring, mackrel, &c. *river*, or *freſh-water fiſh*, *piſces fluviatiles*, as the pike, trout, &c. and *pond*, or *lake-fiſh*, as the carp, tench, &c. to which may be added others which abide indifferently in freſh water or ſalt, as ſalmons, thaſl-fiſh, &c.

Ariſtotle, and after him Mr. Willughby, more accurately diſtinguiſh *fiſh* into *cetaceous*, *cartilaginous*, and *ſpinous*.

The cetaceous *fiſh* are thoſe whoſe tail is ſo placed, that when the *fiſh* is in its natural poſture, it ſtands parallel to the horizon. By this ſituation of the tail, they are enabled to force themſelves ſuddenly to the ſurface of the water to breathe, which they are frequently obliged to do. This ſpecies, like land-animals, breathe by means of lungs, being deſtitute of gills; for this purpoſe they have an orifice on the top of the head, through which alſo they eject water. They copulate alſo like quadrupeds, and conceive and bring forth their young, which they ſuckle with their milk. Many of theſe circumſtances induced Linnæus to place this tribe among his MAMMALIA. The cartilaginous *fiſh* are thoſe whoſe fins ſerving for ſwimming, are ſuſtained by cartilages in the place of the bony rays which ſupport them in the other, and which have alſo cartilages in the whole body, inſtead of bones. They breathe through certain apertures, generally placed on each ſide of the neck, but in ſome inſtances beneath, and in ſome above, and from one to ſeven in number on each part. Many of the cartilaginous *fiſh* are viviparous, being excluded from an egg, which is hatched within them; but ſome, as the ſturgeon and others, are oviparous. This diviſion comprehends the ſame genera to which Linnæus has given the name of AMPHIBIA *nantes*. Theſe are the characters of the two firſt claſſes; and all thoſe *fiſh* which have their fins ſupported by bony rays, which have their tails placed perpendicularly not horizontally, and which have bones, not cartilages in their bodies, are called the *ſpinoſe fiſh*.

The true characters of theſe two great claſſes of *fiſh*, the cetaceous and cartilaginous, are eaſily found; but the characters of the ſpinoſe kinds are to be ſought for deeper, and do not offer themſelves ſo readily. The multitude of theſe, and the great likeneſs between ſeveral of the different genera, render it no eaſy taſk to diſtinguiſh them one from another. Though it be a general rule that the generical characters of *fiſh* are to be taken from their external parts; yet in caſes where theſe external parts differ among themſelves in number, figure, and proportion, it is neceſſary that the primary character of the genus ſhould be taken from thoſe parts which are the leaſt variable of all others; and which are the moſt peculiar to the *fiſh* under conſideration, and the leaſt common to other genera. The utmoſt care and ſkill of the *ichthyologiſt* is neceſſary to the diſtinguiſhing of theſe characters; and on a firſt enquiry he will find, that thoſe parts which ſeem at firſt moſt proper to found diſtinctions on, are in reality leaſt of all ſo. The figure of the fins and tail in *fiſh* might ſeem one of the moſt eſſential characters for a generical diſtinction; yet a farther ſearch into their nature will ſhew that they can be of no uſe at all in this ſenſe. Almoſt all the ſpecies of the cyprini, a genus conſtituted on eſſential and invariable characters, and a truly natural one, have fins acute at the end, and have forked tails; yet had theſe been made characters of the genus, they would have excluded *fiſh* that are properly of it. Thus the tench and the carabſus have both obtuſe fins, and tails ſtraight or plain, not forked at the end. There are indeed many natural genera of *fiſh*, in which the fins and tail are alike in all, as the pearch, the mackrel, the conger. Theſe allow the fins and tail as very good collateral circumſtances of the diſtinctions; but even theſe could not well be diſtinguiſhed by ſuch marks alone, as they are common to many other genera beſides. The figure of the breaſt, the belly, and the back, and the whole figure of the body in regard to length and breadth, are alſo very obvious characters; but they are not eſſential enough to be of any uſe in the diſtinctions of the genera. The back in ſome of the cyprini is ſubacute, as in the common bream; whereas in almoſt all the others it is only moderately convex. This ſets aſide the uſe of the figure of the back as a generical character, ſince the bream notwithſtanding this difference from the reſt of the cyprini, is truly of that genus. The belly, in the far greater number of the cyprini, alſo is plane in the anterior part, and between the pinnæ ventrales and the anus is raiſed into a ridge; but in the tench, the whole belly from the head to the tail is flat. And to this it may be added, that the general figure of the body, as to length or breadth, is extremely different in the cyprini of various ſpecies, as witneſs the bream, the albumus, the ruthus, &c. ſome of which are properly flat, and others almoſt round.

The figure of the HEAD, the MOUTH, the EYES, the NOSTRILS, and other parts belonging to the head, are very different from thoſe variable parts; they are in general fixed and permanent, and are of the utmoſt conſequence in the diſtinctions; but as this figure is too common, and belongs to too many ſpecies equally, they are rather of uſe in diſtinguiſhing the orders, claſſes, and families of *fiſh*, than their genera. Thus the cheſne, the cotti, the corregones, and lumpenus of authors, have a plain general reſemblance in the form of their heads, and yet they are of very different genera.

The figure of the ſcales is generally always the ſame in the ſame genus, and therefore may be made a good collateral circumſtance in the diſtinctions; but as the ſame form is common to the ſcales of many genera, it is impoſſible to bring them to any great uſe in conſtituting the characters of the genera. As to the ſituation of the external parts, as that of the eyes, noſtrils, mouth, and anus, they are generally regular, and alike in all the ſpecies of the ſame genus, regard being had to the proportion; but as their ſituation, though alike in theſe genera, is not peculiar to each, the marks are too common to be uſed as diſtinctive characters for genera. The ſituation of the fins alſo is uſually very regular the ſame in all the ſpecies of the ſame genus; but the ſame objection lies againſt this as againſt the others, in regard to making generical characters from it. The number of TEETH can be of no uſe in making characters of genera; for this very often varies in the ſame ſpecies in different individuals, as in the pike, ſalmon, &c.

In regard to the other external parts of *fiſh*, there are ſome which are found in all the ſpinoſe *fiſh*, and differ in all the ſeveral genera, except thoſe little bones which are found on each ſide in the membrane of the head, which covers the gills. Theſe bones are found in almoſt all the fiſh that have any bones, though in ſome kinds the thickneſs of this membrane makes them leſs conſpicuous than in others. The number of theſe bones is much more regularly and conſtantly the ſame in the ſame genera, than that of the fins, as we may find by many obſervations. The four genera of the *ſcomber*, *gadi*, *perca*, and *ſparoides*, have the number of the fins very various in the ſeveral ſpecies of each genus; but in all theſe genera the number of the bones in the membrane that covers the gills, is regularly the ſame in every ſpecies. All the *gadi* have regularly ſeven bones on each ſide, and ſo on of the reſt. All the *cyprini* have three of theſe bones on each ſide; all the *enſes* have ſix on each ſide; all the *clupeæ* ſeven; all the *ſalmones* eight; all the *eſoces* fourteen; and ſo of the reſt. There are only two known genera of *fiſh*, that do not agree in all the ſpecies in the number of theſe bones; theſe are the ſalmon and the coregoni. In the firſt of theſe the number of the bones is in the ſeveral ſpecies ten, eleven, or twelve; and in the ſeveral ſpecies of the other, there are eight, nine, or ten, and ſometimes but ſeven. It is an obſervation, however, worthy the naturaliſt's conſideration, that nature has given this difference in the number of theſe bones in the ſeveral ſpecies only to thoſe genera in which all the ſpe-

cies have such a ſtrong external reſemblance in all parts, that ſcarce any thing more than the facies externa was neceſſary for knowing that they belonged to one another: for beſide that all the *ſalmon* and *coregoni* have a membranous appendage reſembling a fin on the hinder part of the back, the ſeveral ſpecies of each genus are ſo very remarkably like one another, that it is not eaſy to diſtinguiſh them in many caſes.

As to the number of the fins on *fiſh*, there are a vaſt number of genera which have all the ſame general number, as the *cyprini*, *ſalmones*, *coregoni*, *umbri*, *ſalmones*, *cobitides*, *ejecti*, *pleuronectæ*, *ſpari*, *lupi*, *gobii*, and *gaſteroſteï*; all have ſeven fins radiated with bony ribs. The ſame number of ſeven fins, and thoſe of the ſame kind, is common alſo to the ſeveral other genera; but on the contrary, though all the ſpecies of the ſame genus have conſtantly the ſame number of bones in the membrane that covers the gills, yet it is very rare that the different genera have the ſame number. The *perch*, the *gurnard*, the *ammodytes*, and the *ſcomber*, have indeed all ſeven on each ſide. The *cyprini* and the *gaſteroſteï* have each of them three on each ſide. The *acarus*, the *pleuronectes*, and the *mugil*, have ſix each: theſe, however, are generally ſo very different in their other characters, and in their *facies externa*, that there is not the leaſt danger of their being confounded one with another.

From this it appears very evidently, that the number of theſe bones in the *membrana branchioſtega*, affords the firſt and moſt eſſential of all characters for the diſtinction of the genera of the catheturous and oſteopterygious, or bony-finned *fiſh*. This however is not ſufficient alone, though it is a great aſſiſtant in determining the genera; but in order to bring *fiſh* to their proper genera, it is neceſſary firſt, that all of the ſame genus ſhould have the ſame number of bones in the gills; then, that they ſhould have in the genera the ſame external form and figure; after this, that they muſt have the ſame ſituation of the fins, provided that the number does not differ, which ſometimes has been found to vary in ſpecies truly of the ſame genus; but in general it is, and ought to be, the ſame in all.

The ſituation of the teeth alſo ſhould be the ſame, and this generally holds right in the different genera of *fiſh*, all the ſpecies having in each natural genus the ſame orders of teeth. After this, the ſcales are to be examined, and theſe ought to be of the ſame ſort, and to have the ſame ſituation. Theſe are the circumſtances neceſſary to be enquired into, in regard to the eſtabliſhing of juſt and natural genera. If all theſe agree in all the ſpecies, and, beſide this agreement, there be an analogy in the ſituation and form of the other internal and external parts, particularly in the ſtomach, and its appendices, in the inteſtines, and in the air-bladder, there will remain no doubt of the genus eſtabliſhed on ſuch foundations being perfectly juſt and natural.

It is not to be expected, however, that every one of theſe characters ſhould be found regularly in every ſpecies of the ſame genus in the ſame perfection; ſome will ſhew them more, others leſs, and others will want ſomething of them. But the three grand things that are eſſential to the fameneſs of the genus, are the ſame number of bones in the branchioſtege membrane, and the ſame general external face or figure, and the ſame ſituation of the fins. The other circumſtances are additional and confirmative. Upon the whole it appears, that the number of certain parts is the firſt great foundation of generical diſtinctions in *fiſh*; and that no one note or generical character can be ſo extenſive as to take in the whole at once, but that other characters leſs eſſential but more numerous muſt be in ſome caſes taken in for eſtabliſhing the whole ſeries of *ichthyological* diſtinctions. Artedi, Ichthyolog.

Willughby thinks it would be yet more proper to divide *fiſh* into ſuch as *breathe with lungs*, and ſuch as *breathe with gills*; and then to ſubdivide thoſe that breathe with gills, not into cartilaginous and ſpinous, but into *viviparous* and *oviparous*.

The *viviparous* kind that *breathe with gills*, he ſubdivides into *long*; ſuch as the *galei* and *canes*, or ſharks and dog-*fiſh*; and broad, ſuch as the paſſinaca, raja, &c. the ſubdiviſions of each whereof, he gives in his chapter of cartilaginous *fiſh* in general.

The *oviparous* kind that *breathe with gills* are the moſt numerous; and theſe he ſubdivides into ſuch as are what we uſually call *flat-fiſhes* and ſuch as ſwim with their back upright, or at right angles to the horizon.

The *plain* or *flat-fiſh* kind, called uſually *pleni ſpinoſi*, are either *quadrati*, as the rhombi and paſſeres: or *longiuſculi*, as the ſoleæ.

Such as ſwim *with their backs erect*, are either long and ſmooth, and without viſible ſcales, as the eel-kind; or ſhorter and leſs ſmooth; and theſe have either but one pair of fins at their gills, or elſe another pair of fins alſo on their bellies; which latter kind he ſubdivides into two kinds, 1. Such as have *no prickly fins on their backs*, but ſoft and flexible ones. 2. Such as have *prickly fins* upon their backs.

Thoſe *fiſh* which have only ſoft and flexible fins on their backs, may be divided into ſuch as have *three*, *two*, or but *one* ſingle fin there.

No *fiſh* but the alleſa have *three* FINS on their backs.

Fiſh with *two fins* on their backs are either the trutinaceous, trout kind; or the gobioniires, loch, or gudgeon kind.

Fiſh with but *one ſoft back-fin* are of three ſorts. The firſt kind have one long continued fin, from head to tail, as the hippurus of Rondeletius, &c.

The ſecond have their fins but ſhort, and placed juſt in the middle of their backs: and theſe are either *marine*, as the herring-kind; or *fluviat.le*, as thoſe which we call *leather-mouthed fiſh*: ſuch as carp, tench, &c.

Fiſh which have *prickly fins on their backs*, are of two kinds. 1. Such as have *two prickly fins on their backs*; and in theſe the anterior rads of their fins are always prickly. 2. Such as have but *one prickly fin* there.

The northern countries abound in large and delicate *fiſh* even to the extremeſt degrees of cold. Scheffer, in his Hiſtory of Lapland, gives us a wonderful account of the abundance and large ſize of the *fiſh* there.

The ſalmon grow to a larger ſize than we ever ſee them, and are caught in ſuch abundance that the natives who pickle them ſometimes export not leſs than thirteen thouſand tuns in a year; pike are very common, and grow to the length of ſix or ſeven feet, and a proportionable thickneſs.

The carp grow to an ell long, and often conſiderably more; and trout, barble, gudgeons, and pearch, grow to a proportionable ſize and fatneſs. The laſt of theſe *fiſh* have one thing very peculiar among them; they ſuck the ſkins in water, and then ſtripping off the ſcales, they add freſh water, and boil the ſkins down till wholly diſſolved: of this they make a very pure and beautiful ſort of glue, which is not inferior in ſtrength to our coarſe and ſlinking kind.

The coming of certain kinds of *fiſh* in ſhoals and infinite multitudes, to certain coaſts at certain times of the year, is a thing of great advantage to mankind, as it gives opportunities of taking them with great eaſe, and in vaſt quantities; but the reaſon of theſe periodical returns of the ſeveral kinds does not ſeem much underſtood, though a little obſervation would probably clear it up. There is a ſmall inſect common in many ſeas, but peculiarly plentiful on the coaſts of Normandy in the months of June, July, and Auguſt. This is well deſcribed by Rondeletius, under the name of the ſea-caterpillar; and at this time of the year it is ſo frequent in the place before mentioned, that the whole ſurface of the water is covered with it as with a ſcum. This is the ſeaſon of the year when the herrings come alſo in ſuch prodigious ſhoals to thoſe coaſts. The fiſhermen complain much of theſe naſty vermin, which diſturb their fiſheries; but they do not conſider that it is to theſe alone that their fiſheries are owing; for it is evident, that the herrings feed on theſe creatures greedily, by the vaſt quantity found in all their ſtomachs, and it is highly probable, nay ſcarce to be doubted, that the reaſon of thoſe *fiſh* coming up in ſuch numbers is to feed on them; probably, if obſervation was made, the ſame would be found to be the caſe in all the other places where the herrings come in the ſame ſort of plenty. The mackrel come down in the ſame numbers regularly at certain times of the year, and for the ſame ſort of reaſon. This *fiſh* is an herb-eater, and is particularly fond of that ſea-plant called by naturaliſts the narrow-leaved purple palmated ſea-weed; this grows in great abundance on the coaſts of England, and many other places, and is in its greateſt perfection in the beginning of the ſummer, though ſometimes later than others, according to the ſeverity or mildneſs of the winter.

The whole occaſion of theſe *fiſh* coming in ſuch quantities is to feed on this plant; and thoſe who would attend to its growing up, would know when to expect the mackrel better than thoſe who liſten for thunder for the ſignal of them. The tunnies come at certain ſeaſons to the coaſts of Provence and Languedoc, in the ſame ſhoals that herrings and mackrel do to other places. This ſeems to be on another occaſion: the *fiſh* called by the French the *empereur*, and by the ſame confounded with the ſword-fiſh, is the great enemy of theſe *fiſh*, and in ſummer is ſo pleniful in thoſe ſeas, that they find no way of ſaving themſelves, but by flying to the ſhallow waters where the other cannot eaſily follow them; hence they frequent the ſhores. The pilchards caught upon the coaſts of Britany, and making a conſiderable article of commerce for that province, are yet a ſtronger

proof

preed of the natural means that bring *fish* in shoals to certain places, than any other. These *fish* evidently come for food, and that not natural to the place, but prepared for them by the inhabitants.

The people of Brittany purchase from Norway the offal and entrails of all the large fish caught in the northern seas; this is of late years become a regular and considerable article of trade; they cut these to pieces, and strew them in vast quantities over the whole surface of the sea along their coasts, at times when the winds do not sit to as to blow it off.

This always brings together the pilchards in as vast shoals, as the herrings or mackrel come in other places; and the fishermen catch them in such quantities, as to be able to supply all the maritime places in the neighbourhood with them at a small price. The salmon, a *fish* bred in rivers, yet going at certain times to the sea, is another of those *fish* which come up at times in vast shoals. See SALMON.

Small *fish* may very well be kept in glass-jars with fresh water; and those of prey are very fit to be tamed by this means.

Some of these creatures often have no other sustenance than the animalcula of the water they are put in. Phil Trans. N° 478. p. 26. See DACE and RUFF.

Mr. Bovie speaks of a kind of *fish* on the coast of Ireland, the hearts of which are found inverted. Works abridg. vol. i. p. 27.

In the Philosophical Transactions, N° 463. sect. 1. we have a method of preparing *specimens* of *fish*, by drying their skins, as practised by Dr. Gronovius.

FISH, *black, of Aleppo*, or *Sciæna Angustaris* of Linnæus, is described by Dr. Russel as resembling, in its shape, the SILURUS *Remautis*, and like it having no scales. The head and back are black; the lateral line runs quite from the head to the tail, on the middle of the side; below which to the belly, the colour generally changes to a dark purple. The under part of the head is also of the same colour. The head is flat, and about five inches long; the body is round and near the tail becomes flat. The mouth is not to large in proportion as that of the silurus; it has no tongue, and the structure of the mouth and palate agrees exactly with the description of that *fish*. A small cirrus arises on each side from the edge of the postil, and two others twice as long, and much stronger, from the angles of the mouth. These are also four on the lower lip; the eyes are situated near the corner of the mouth; the branchiæ are four on each side, with a double row of sharp points. Near the branchiæ there are two fins, composed of seven radii; to the anterior part of which joins a pretty strong prickly bone. Above the anus are two smaller fins; a long fin extends from under the anus to the tail, and another from the neck along the back; neither of which join with the tail. This *fish* is found in the river Orontes, and in stagnant waters near it. The markets of Aleppo are plentifully supplied with it from November to March. The flesh is red like beef, and of a rank taste, and esteemed unwholesome, though for want of better much eaten. Hist. Aleppo, p. 73.

FISH, with regard to commerce, is distinguished into *dry*, *pickled*, *green*, and *red*.

FISH, *dry* or *salt*, is that which is salted and dried either by the heat of the sun, or by fire. Such principally are the cod, stock-fish, herring, and pilchard. See *Cod* FISHERY.

FISH, *green*, is that lately salted, and which yet remains moist: as green cod, &c.

FISH, *pickled*, is that boiled and steeped in a pickle made of salt, vinegar, &c. as salmon, cod, herring, mackrel, pilchard, anchovy, and oysters.

FISH, *red*, is some fresh *fish* broiled on the gridiron, then fried in oil of olives, and barrelled up with a proper liquor, as new olive oil, vinegar, salt, pepper, cloves, and laurel leaves, or other herbs. The best *fish* thus prepared are sturgeon and tunny.

FISH, considered as a food makes a considerable article in the furniture of the table; and the breeding, feeding, catching, &c. thereof, make a peculiar art of no small moment in the œconomy of a gentleman's house and garden.

To this relate the ponds, stews, &c. described in their proper places. See *Fish-pond*, STEW, &c.

FISH, *blowing of*, is a practice similar to that of blowing fowls, poultry, and pigs, and adopted for the same deceitful purposes. The method of blowing *fish*, especially cod and whitings, is by placing the end of a quill or tobacco-pipe at the vent, and pricking a hole with a pin under the fin which is next the gill; thereby making the *fish* appear to the eye large and full, which when dressed will be flabby, and little else than skin and bones. But this imposition may be discovered by placing the finger and thumb on each side of the vent, and squeezing it hard; the wind may be perceived to get out, the skin will fall in, and the *fish* appear lank and of little value.

FISH, *breeding of*. See FISH-*pond*.

FISH, *coffration of*, is a method first practised by Mr. Tull, in order to prevent the excessive increase of *fish* in some of his ponds, where the numbers did not permit any of them to grow to an advantageous size. But he afterwards found, that the caftrated *fish* grew much larger than their ufual fize, were more fat, and always in feafon. This operation may be performed both on male and female *fish*; and the moft eligible time for it is when the ovaries of the female have their *ova* in them, and when the veffels of the male, analogous to thefe, have their feminal matter in them; becaufe, at this time, thefe veffels are more eafily diftinguifhed from the ureters, which convey the urine from the kidneys into the bladder, and are fituated near the feminal veffels on each fide of the fpine; which, without fufficient attention may be miftaken for the ovaries, efpecially when thefe laft are empty. The time leaft proper for this operation, is juft after they have fpawned, becaufe the fifh are then too weak and languid to bear with fuccefs, fo fevere an operation; however, with fkill and care, it may be performed almoft at any time. When a *fish* is to be caftrated, it muft be held in a wet cloth, with its belly upwards; then with a fharp pen-knife, having its point bent backwards, the operator cuts through the integuments of the rim of the belly, taking care not to wound any of the inteftines. As foon as a fmall aperture is made, he carefully inverts a hooked pen-knife, and with this dilates this aperture from between the two fore-fins, almoft to the anus. He then, with two fmall blunt filver-hooks, five or fix inches long, and of this form [illegible], by the help of an affiftant, holds open the belly of the *fish*; and, with a fpoon or fpatula, removes carefully the inteftines from one fide. When thefe are removed, you fee the ureter, a fmall veffel, nearly in the direction of the fpine, and alfo the ovary, a larger veffel, lying before it, nearer the integuments of the belly. This laft veffel is taken up with a hook of the fame kind with thofe before mentioned, and, after detaching it from the fide far enough for the purpofe, divided tranfverfely with a pair of fharp fciffars, care being taken, that the inteftines are not wounded or injured. After one of the ovaries has been divided, the operator proceeds to divide the other in the fame manner: and then the divided integuments of the belly are fewed with filk, the ftitches being inferted at a fmall diftance from one another. Mr. Tull obferves farther, that the fpawning time is very various; that trouts are full about Chriftmas; perch in February; pikes in March, and carp and tench in May; and that allowance muft be made for climates and fituation, with regard to the fpawning of *fish*. When the *fish* are caftrated, they are put into the water where they are intended to continue; and they take their chance in common with other *fish*, as though they were not caftrated. With tolerable care, few die of the operation. Phil. Tranf. vol. xlviii. part ii. art. 106.

FISH, *eyes of*. See EYES.

FISH, *fecundity of*, has been taken notice of by various writers, who have furnifhed inftances of it in fome particular fpecies that have been thought furprifing. M. Petit is faid to have found in the carp 342,144 eggs; and Lewenhoeck in a cod of middling fize 9,384,000. But Mr. Harmer has lately purfued the inveftigation of this curious fubject with peculiar attention and accuracy, and extended his enquiries to a greater variety of fpecies than any other perfon. The method which he adopted was that of weighing the whole fpawn very exactly; he then took a piece weighing a certain number of grains, and carefully counted the eggs contained in it; and by dividing the number of eggs by the number of grains, he found, nearly, how many eggs there were in each grain. His computation of the number of eggs extended no farther than to thofe which he could diftinguifh with his naked eye; though by this limitation, he omitted many eggs, difcoverable by a microfcope, that might juftly have been counted. The weights he ufed were avoirdupois, and he reckoned 437½ grains to an ounce.

The following table exhibits the general refult of his enquiries: the firft column contains the names of the *fish* which he examined; the fecond, their weight; the third, the weight of their fpawn; and the fourth their fecundity; and the fifth the time of the year, when each fpecies of *fish* was examined. He has alfo added other columns, exhibiting the portion of fpawn weighed, and the number of eggs found in a grain, and the refult of examining feveral varieties of the fame fpecies of *fish*, of different weights, which the curious reader may conſult. See Phil. Tranſ. vol. lxii. for 1767. art. 30. p. 280.

Abstract of the Table.

Fish	Weight oz.	Weight dr.	Weight of spawn. Grains.	Fecundity. Eggs.	Time.
Carp	25	8	2571	203109	April 4.
Cod-fish	———		12540	3686700	Dec. 23.
Flounder	24	4	2200	1337400	Mar. 14.
Herring	5	10	480	30960	Oct. 25.
Ladder	38	0	1671	21069	Aug. 11.
Mackrel	18	0	12235	546081	June 18.
Perch	8	9	765½	28323	April 5.
Pike	56	4	5100½	40304	April 25.
Prawn	(127 grains)		———	3806	May 12.
Roach	10	6½	361	81586	May 2.
Shrimp	(39 grains)		7	6807	May 3.
Smelt	2	0	149½	38278	Feb. 21.
Soal	14	8	542½	100362	June 13.
Tench	40	0	———	383252*	May 28.

* N. B. Part of the spawn of this *fish* was accidentally loft, and therefore this number is considerably too small.

FISH, *feeding of*. 1. In a ſtew, thirty or forty carps may be kept from October to March, without feeding; and, by filling with trammels, or ſtews, in March or April, you may take from your great waters, to recruit the ſtews: but you muſt not fail to feed all ſummer, from March to October again, as conſtantly as cooped chickens are fed; and it will turn to as good an account.

2. The conſtancy and regularity of ſerving the *fish* conduces very much to their well-eating, and thriving.

The care of doing this, is beſt committed to the gardener, who is always at hand, and on the ſpot.

3. Any ſort of grain boiled is good to feed with, eſpecially peas and malt, coarſe ground; the grains after brewing, while freſh and ſweet, are alſo very proper; but one buſhel of malt, not brewed, will go as far as two of grains; chippings of bread, and orts of a table, ſteeped in tap-droppings of ſtrong beer, or ale, are excellent food for carps. Of theſe the quantity of two quarts to thirty carps, every day, is ſufficient; and to be ſo fed morning and evening, is better than once a day.

There is a ſort of food for *fish*, that may be called accidental, and is no leſs improving than the beſt that can be provided; and this is when the pools happen to receive the waſh of commons, where many ſheep have paſture, the water is thus enriched by the ſoil, and will feed a much greater number of carps than otherwiſe it would do; and farther, the dung that falls from cattle ſtanding in water in hot weather, is alſo a very great nouriſhment to *fish*. See farther on the method of feeding carp, and the advantages reſulting from it, under the article CARP.

The beſt food, to raiſe pikes to an extraordinary fatneſs, is eels; and without them it is not to be done, but in a long time. Setting theſe aſide, ſmall perches are the beſt meat. Breams put into a pike pond breed exceedingly, and are fit to maintain pikes; which will take care they do not increaſe overmuch; the numerous fry of roaches and rudds, which come from the greater pools into the pike quarters, will likewiſe be good diet for them.

The in all ſtreams, and carp in hungry ſpringing waters, being fed at certain times, will come up and take their meat almoſt from your hand.

The beſt feeding place is toward the mouth of the pond, at the depth of about half a yard; for by that means the deep will be kept clean and neat; the meat thrown into the water, without other trouble, will be picked up by the *fish*, and nothing will be loſt; yet there are ſeveral devices for giving them food, eſpecially peas; as a ſquare board like a trencher, ſupported by four ſtrings, one at each corner, with leads at the bottom for ſinking it, on which the food may be let down into the water.

When *fish* are fed in the larger pools or ponds, where their numbers are great, malt boiled, or freſh grains, is the beſt food. Thus carps may be fed and raiſed like capons, and tench will feed as well; but perch are not for a ſtew in feeding-time.

FISH, *generation of*. The general opinion of the world as to the generation of *fish*, is, that the female depoſits her ſpawn or eggs, and that the male after this ejects the ſperm or male ſeemen upon it in the water, by which it is fecundated. The want of the organs of generation in *fish*, gives an apparent probability to this; but Linnæus is greatly againſt it. He affirms that there can be no poſſibility of the impregnation of the eggs of any animal out of its body.

To confirm this, the general courſe of nature not only in birds, quadrupeds, and inſects, but even the vegetable world, has been called in to his aſſiſtance, as proving, that all impregnation is performed, whilſt the ova are in the body of the parent; and he ſupplies the want of the organs of generation by a very ſtrange proceſs, affirming that the males eject their ſemen always ſome days before the females depoſit their ova or ſpawn, and that the females ſwallow this, and have their eggs by that means impregnated by it.

He ſays, that he has often ſeen three or four females at this time frequently gathered about the male, and greedily ſnatching up into their mouths the ſemen he ejects: he mentions four of the cyprini, ſome pearch, and ſome of the cyprini, in which he has ſeen this proceſs. Mr. Hall aſſerts, that he has frequently ſeen *fish* in actual copulation; and that this is generally done before the ova arrive at maturity. Phil. Tranſ. vol. xlviii. part ii. art. 106. p. 873.

FISH, *generical names of*. See GENERICAL *name*.

FISH, *gilding of*. See GILDING.

FISH, *hearing of*. When the lapilli or bones in the heads of *fish*, which are truly their organs of hearing, are examined in the heads of the ſeveral kinds, it appears, that they differ from one another both in their ſtructure and ſubſtance. For in the cetaceous fiſh, whoſe ſkeletons are truly bony, and which in certain reſpects may be compared to truly lignéous trees, both the os petroſum, and the auditory organs, are in theſe as in other animals, perfectly oſſeous or bony; whereas the cartilaginous *fish*, whoſe ſkeletons are ciſtilic, and are cartilaginous rather than bony, may be compared to the keratophyta, or tough horny ſea plants; and theſe *fish*, inſtead of an os petroſum, have ſomething analogous; but it is cartilaginous not bony, and the auditory bones are of a tartareous kind of ſubſtance, being friable, and eaſily crumbled to pieces. See EAR.

It has been a diſputed point among the naturaliſts of many ages, whether *fish* hear or not; it is plain that the cetaceous *fish* have all of them auditory paſſages or ear-holes, but it has not been found, that any other *fish* have any appearance of them. Many authors have been fond of believing that all *fish* have hearing; but theſe arguments in general are inconcluſive.

Among the anciens, many authors appear to have been poſitive in the opinion, that *fish* had hearing, though they were by no means ſatisfied about the ways or paſſages by which they heard. Placentini afterwards diſcovered ſome bones in the head of the pike, which had very much the appearance of being organs of hearing, but he could never diſcover any external paſſages to them. Klein ſeems to be the only author who has improved upon this hint to any purpoſe; and he affirms and proves from experiments and obſervations, that all *fish* have the organs of hearing, and have alſo paſſages from without to thoſe organs, though in many ſpecies they are diſficult to be ſeen, and that even the moſt minute and obſcure of theſe are capable of communicating a tremulous motion to thoſe organs from ſounds ariſing from without; nor does the water appear on ſerious conſideration to be any impediment, but rather a proper medium for the conveying of the ſounds to ſuch organs; and it appears no way more ſtrange, that they ſhould hear through the water, than that a man ſhould hear in one room the words pronounced in another, though there is a partition between them.

The organs of hearing in *fish* are indiſputably the little bones commonly called lapilli, and found in the heads of all *fish*; theſe are conſtituent and eſſential parts in the head of *fish*, and are generated with the brain itſelf; not an accidental thing as ſome have believed them to be. They are always found to differ in magnitude according to the ſize of the *fish* they belong to; and they are more eaſily diſtinguiſhed in the heads of the ſpinoſe *fish*, than in any other kind. There are in all kinds of *fish* three pair of them; the firſt are the two largeſt bones, and are eaſily enough found, but the greateſt difficulty lies in diſcovering the other two pair, which are ſmall, and lie enveloped in diſtinct little bags compoſed of a fine membrane. Theſe ſeem to be the auditory organs, and to anſwer to the incus, malleus, and ſtapes, in other animals; and by a diligent and careful inſpection, the age of a *fish* may be determined by the number and thickneſs of the lamine and fibres of theſe bones, in the ſame manner as the age of a tree is known by the number of circles of the wood. The paſſages by which a tremulous motion is conveyed from without to theſe internal organs are to be diſcovered with care in moſt *fish*, and in particular in the pike; though Placentini could not diſcover them there. A cloſe examination of the head of this *fish* will ſhew ſeveral holes into which the bridles may be thruſt, and theſe will be found to go directly into the internal auditory organs; and in diſſecting the head of a ſturgeon, the auditory duct is eaſily traced as far as the membranous body, in which the three ſets of little bones are placed. Curious figures of theſe auditory ducts, and of the great variety of theſe officials of

lapilli, are exhibited in Klein's Hiſtory of *Fiſh*, to which we refer, as much more expreſſive than any form of words can be. See an account of Klein's book in Phil. Tranſ. abr. vol. ix. p. 114, &c.

Mr. Baker aſcribes to the exquiſite ſenſibility of the organs of ſight and feeling in *fiſh* thoſe effects, which others have urged as arguments of their poſſeſſing the faculty of hearing, in Phil. Tranſ. vol. xiv. art. 4. p. 153 However, M. Camper has more lately endeavoured to ſhew, that *fiſh* are really endowed with this ſenſation, and deſcribed the organs adapted to this purpoſe in ſome particular ſpecies. Mem. de Mathem. & Phyſ. Roy. Acad. Sc. Paris, vol. vi. 1774. And the abbe Nollet has long ſince evinced, by diving under water for this purpoſe, that water is capable of receiving and tranſmitting to the animals contained in it, thoſe peculiar impreſſions that conſtitute ſound. Mem. de l'Acad. 1743.

FISH, in *Heraldry*. See HERALDRY.

FISHER, in *Zoology*. See SABLE.

FISHERY, a commodious place for *fiſhing*; or a place wherein great quantities of *fiſh* are caught.

The principal *fiſheries* of Europe for ſalmon, herring, cod, and mackrel, are along the coaſts of England, Scotland, and Ireland; for cod, on the banks of Newfoundland; for whales, about Greenland; for pearls, in the Eaſt and Weſt Indies, &c.

FISHERY alſo denotes the commerce of *fiſh*; more eſpecially the catching of them for ſale. The *fiſhery* makes a principal branch of the Britiſh commerce. A great quantity of veſſels and ſeamen are employed therein; and beſides what is ſpent at home, large ſums are yearly returned, merely for herring, cod, and pilchards, exported to Spain, Italy, and ſeveral parts of the Mediterranean, and the iſlands of the Archipelago.

Yet are our countrymen reproached, and with a good deal of juſtice, for their remiſſneſs in this branch of trade. The advantageous ſituation of our coaſts might be of immenſe benefit to us, did not we let our neighbours overreach us therein. The Dutch, French, Hamburghers, &c. come yearly in large ſhoals, and not only take the fiſh from our own coaſts, but ſell them to us for our money, when they have done.

Scotland ſuffers incredibly on this ſcore: no country in Europe can pretend to rival it in the abundance of the fineſt fiſh, wherewith its numerous harbours, loughs, rivers, &c. are ſtored. In the river Dee, it is ſaid, an hundred and ſeventy head of ſalmon is not very extraordinary for a ſingle draught of a net; and the pickled ſalmon ſent hence is allowed the beſt in Europe. The Scottiſh iſlands, eſpecially thoſe on the weſtern ſide, do certainly lie the moſt commodiouſly for carrying on the fiſhing-trade to perfection.

King Charles the firſt began the experiment in 1630 and 1633, in conjunction with a company of merchants; but the civil wars ſoon ſet it aſide. King Charles the ſecond, in 1661, made a like attempt; but having preſſing occaſion for money, he was perſuaded to withdraw what he had employed in the *fiſhery*; at which the merchants, joined with him, being diſpleaſed, did the like themſelves.

Since the Union, ſeveral efforts have been made to retrieve it; and in 1750 there was a corporation ſettled on that footing by parliament, called the *Free Britiſh Fiſhery*, for the term of twenty-one years, under the direction of a governor, preſident, vice-preſident, council, and other officers, who were empowered to make byelaws, &c. and to raiſe a capital of 500,000*l.* and the Scotch *fiſhery*, encouraged by fiſhing chambers, erected in ſeveral cities, is likely to be put on a very advantageous baſis. See *Herring* FISHERY.

FISHERY, *anchovy*. See ANCHOVY.

FISHERY, *cod*. The cod is a fiſh of paſſage, pretty large, with a great head, and teeth in the bottom of the throat; its fleſh white; its ſkin browniſh on the back, white under the belly, and covered with a few thin tranſparent ſcales. See COD.

It eats excellently when freſh: and, if well prepared and ſalted, will keep a long time. This fiſh, thus prepared, is commonly eaten among us in Lent, &c. under the denomination of *ſalt-fiſh*, or *ſtock-fiſh*.

There are two kinds of *cod-ſea*; the one called *green*, or *waſhes*; and the other *dried*, or *corned*; though it is the ſame fiſh, only differently prepared.

They are alſo diſtinguiſhed by the places from whence they are brought, as well as by the manner of curing, into Aberdeen-fiſh, Iceland-fiſh, green-fiſh, ſtock-fiſh, North-ſea cod, poor Jack, and barrelled cod.

Green cod.—The chief *fiſheries* for *green cod* are in the bay of Canada, on the Great and Little Bank, near the coaſt of Newfoundland, the iſle of St. Peter, and the iſle of Sable; and thither veſſels are yearly ſent from divers parts both of America and Europe.

The veſſels uſed herein are from a hundred to a hundred and fifty tons burden; and theſe will bring thirty or thirty-five thouſand fiſh a-piece.

The moſt eſſential articles in this *fiſhery* are the perſons who know how to open the fiſh, to cut off the heads, and to ſalt them; upon the ability of which laſt the ſucce of the voyage chiefly depends.

Several authors will have it, that the Biſcayans, in purſuing their whales, made the firſt diſcovery of the Grea and Little Banks of *cods* at Newfoundland, Canada, &c. a hundred years before Columbus's time; and that it was a Biſcayan Newfoundlander that gave the firſt intimation thereof to Columbus.

Others ſay, that the Great Bank was diſcovered by a native of St. Malo's, named Cartier. But be the diſcoverer of what name or nation he may, the diſcovery is certainly highly valuable; there is not a trading nation in Europe, but allows the commerce of *cod-fiſh* one of the moſt ſecure and gainful that is known.

The beſt, largeſt, and fatteſt *cod* are thoſe taken on the ſouth-ſide of the great Bank, which is a kind of ſubmarine mountain, one hundred and fifty miles long, and fifty broad, and at the diſtance of twenty-five leagues from Newfoundland: thoſe on the north-ſide are generally much ſmaller.

The beſt ſeaſon is from the beginning of February to the end of April; at which time the *cod*, which during the winter had retired to the deepeſt part of the ſea, return to the Bank, and grow very fat.

Thoſe caught from March to June keep well enough; but thoſe taken in July, Auguſt, and September, ſoon ſpoil. The fiſhing is ſometimes done in a month, or ſix weeks; and ſometimes it holds four or five months. As Lent draws on, if the fiſhermen have but half their cargo, they ſtrive who ſhall make homeward the firſt; the market being then the beſt.

Some will thus make a ſecond voyage, before others have got loading for the firſt. Each fiſher only takes one cod at a time; and yet the more experienced will take from three hundred and fifty to four hundred *per day*; but this is the moſt; for it is very fatiguing work, both on account of the weight of the fiſh, and of the extream cold which reigns on the Bank.

The wages uſually allowed the captain and ſailors, is one third of the *coſt* they bring home ſound.

They ſalt the *cod* on board. The head being cut off, the belly opened, and the guts taken out, the ſalter ranges them in the bottom of the veſſel, head to tail; and having thus made a layer thereof, a fathom or two ſquare, he covers it with ſalt; over this he lays another layer of fiſh, which he covers as before: and thus he diſpoſes all the fiſh of that day, taking care never to mix the fiſh of different days together.

By that time the *cod* has lain thus to drain three or four days, they are moved into another part of the veſſel, and ſalted afreſh. After this, they are no more to be touched, till the veſſel have its burden.

Sometimes they put them up in barrels, for the conveniency of carriage.

Dry cod.—In the fiſhing of *dry cod*, veſſels of all ſizes are uſed; though ſuch are generally choſen, as have large holds, becauſe this ſort of fiſh incumbers more than it burdens.

As *cod* is only to be dried by the ſun, the European veſſels are obliged to put out in March, or April, to have the benefit of the ſummer for drying. Indeed, we ſend veſſels for *cod* in June and July; but thoſe only buy what had been ſalted and prepared by the inhabitants of the Engliſh colonies of Newfoundland, and the neighbouring parts; in exchange for which, we carry them meal, brandies, biſcuits, pulſe, melaſſes, linen, &c.

The principal *fishery* for *dry cod* is along the coast of Placentia, from Cape Rose, to the Bay des Experts; in which compass there are divers commodious ports for the fish to be dried in.

The fish intended for this use, though of the same kind with the green cod, is yet much smaller; whence it is the fitter to keep, as the salt more easily penetrates it.

The method of fishing is much the same in both; only this latter is the more expensive, as it takes up more time, and employs more hands; and yet scarce half so much salt is spent in this, as in the other.

When several fishing vessels meet, and intend to fish in the same port, he whose shallop first touches ground, becomes entitled to the quality and privileges of ADMIRAL; he has the choice of his station, and the refusal of all the wood on the coast at his arrival.

As fast as the captains arrive, they unrig all their vessels, leaving nothing but the shrouds to sustain the masts, and in the mean time the mates provide a tent on shore, covered with branches of fir, and sails over them; with a scaffold, fifty or sixty feet long, and about one third in breadth.

While the scaffold is making ready, the crew are fishing; and as fast as they catch, they bring their fish, open them, and salt them on moveable benches; but the main salting is performed on the scaffold, called PLAKE.

When the fish have taken salt, they wash them; and to drain them again, lay them in piles on the galleries of the scaffold; when drained, they range them on hurdles, a fish thick, head against tail, with the back uppermost; observing, while they lie thus, to turn and shift them four times every twenty-four hours.

When they begin to dry, they lay them in heaps of ten or twelve a-piece, to retain their warmth, and continue to enlarge the heap every day, till it becomes double its first bulk: at length they join two of these heaps into one, which they turn every day, as before. Lastly, they salt them over again, beginning with those that had been salted first; and thus lay them in huge piles, as big as haystacks.

In this manner they rest, till they are carried a-ship-board, where they are laid on branches of trees, disposed for that purpose in the bottom of the vessel, with mats all around to prevent their contracting any moisture.

There are four kinds of commodities drawn from *cod*; viz. the sounds, and tongues, which are salted at the same time with the fish, and barrelled up; the roes, or eggs, which, being salted and barrelled up, serve to sell into the sea, to draw fish together, and particularly pilchards; and lastly, the oil, which is used in dressing of leather, &c.

By the definitive treaty between Great Britain and France in 1763, the French are now absolutely deprived of the powerful fortifications of Cape Breton, and of the possession of Canada and all its dependencies; and are entitled to no possessions contiguous to Newfoundland; except the small islands of St. Peter's and Miquelon, ceded by the sixth article of the said treaty to his most Christian majesty, as a shelter for the French fishermen; and his most Christian majesty engages not to fortify the said islands, to erect no buildings upon them, but merely for the convenience of the *fishery*, and to keep upon them a guard only of fifty men for the police. And by the eighteenth article of the same treaty, it is expressly stipulated between Great Britain and Spain, that his Catholic majesty declares, as well for himself, as for his successors, from all pretensions which he may have formed in favour of the Guipuscoans and other his subjects, to the right of fishing in the neighbourhood of Newfoundland.

The Scots catch a small kind of *cod* on the coasts of Buchan, which is highly prized, though very much like ling. They salt it, and dry it in the sun, upon rocks; and sometimes in the chimney; but the greatest part of it is spent at home.

FISHERY, *coral*. See CORAL.

FISHERY, *herring*. The *herring* is a small salt-water fish, with a bluish back, and a white silvered belly, not unlike a little shad-fish; whence it is called in Latin *alosa minor*. Rondeletius calls it *harengus*.

It is a popular error to believe the *herring* to be the *halec* of the Romans. The *halec* was no particular fish, but a kind of sauce, made of any kind of salt-fish. The modern *herring* seems to have been unknown to the ancients: it is neither the *halec*, nor *maena*, nor *harengus*, nor the *garum* of Pliny. See Rondelet. De Pisc. Marin. lib. v. cap. 13. and Vossius De Idolol. See HERRING.

Herrings are chiefly found in the North sea. It is true, there are *fisheries* elsewhere, but none so copious.

They usually make two fishing seasons for *herrings*; the first in June, July, and August; the second in autumn; the latter of these is the more considerable, on account of the fogs, which are very favourable to this kind of fishing.

It is commonly said, that nobody ever saw a *herring* alive, and that they die the minute they are taken out of the water; but there are instances to the contrary.

The *herring* is a fish of passage; so that it is allowed to catch them on holidays and Sundays: in the Decretal there is an express chapter to this effect. They go chiefly in shoals and are fond of following any fire, or light; and in their passage they resemble a kind of lightning themselves.

About the beginning of June, a shoal of herrings, in bulk not less than the whole extent of Great Britain and Ireland, comes from the North, on the surface of the sea; and their approach is known to the Shetlanders by several tokens in the air and water; as by the birds, such as gannets, and others, which follow, to prey on them, and the smoothness of the water. It is not certainly known from whence they come; though it is probable that their winter rendezvous is within the arctic circle, where the seas swarm with insect food in greater abundance than in our warmer latitudes. But when they arrive in these seas, they cast their spawn; for they come to us full, and are shotten long before they leave us. As the great shoal formed by the migrating herrings, and divided into distinct columns, five or six miles in length, and three or four in breadth, reflecting in bright weather many splendid colours, passes between the shores of Greenland and the North Cape, it is probably much straitened, and as it reaches the extremities of Great Britain, it is separated into two parts: one part steers west or south-west, and, leaving the islands of Orkney and Shetland to the left, passes on towards Ireland; where being interrupted by that island, this part is again divided; some, keeping to the coast of Britain, go southward down St. George's or the Irish channel, and the others, edging off for want of room to the west and south-west, go along the Hibernian ocean, and, keeping on the coast, reach the south shore of Ireland, from whence they steer southward, and join the rest in the Irish channel. The other part of the first division made in the north, parting a little to the east and south-east, come down into the German ocean: they pass by Shetland, and make the point of Buchaness, and the coast of Aberdeen, filling the bays, friths, rivers, and creeks, with their innumerable multitudes. Hence they proceed southward, pass by Dunbar, and rounding the high shores of St. Tobbs and Berwick, are seen again off Scarborough, and not before, but not in bulk, till they come to Yarmouth roads in England, and thence to the mouth of the Thames; from whence passing the British channel, they are seen no more in any number. The herrings are found again on the shores of North America, though not in such quantities as with us; and they are seen no farther south than the rivers of Carolina. Whether these may be part of that large shoal, which, at their first coming by the coast of Greenland, keep to the coasts of America on the north-west side; or whether they are the remainder of those that pass our channels, is uncertain; but we know that they are not seen in quantities in any of the southern kingdoms, as Spain, Portugal, or the south parts of France, on the side of the ocean, or in the Mediterranean, or on the coast of Africa.

The Hollanders were the first who began the *herring-fishery*, and observed the several seasons of their passage. Their first regular fishing is fixed to the year 1164.

In the year 1313 we have an account of the seizure of a ship of Lynn, in the port of Bergen, which had been fishing on the Norway coast for herrings. Rymer's Fœd. vol. iii. p. 400. And as lastings of herrings carried to a distance must have been salted, it is plain that salted herrings, either wet or else dried, called *red* herrings, were, in those times, a merchantable commodity in foreign parts. And in 1338 we have an account of fifty lasts of herrings shipped from Portmouth for the use of the army and fleet of Edward III. in Gascony, which must have been salted, either wet or dried. Fœd. vol. v. p. 12. And they were barrelled and salted at the port of Whitby in Yorkshire, in 1304. Fœd. vol. iii. p. 778.

But the present method of pickling them was not discovered till the year 1416, though others date it from the year 1397. Willughby, in his History of Fishes, observes, that Will. Buckelfs, or Beukalen, a native of Bier Ulset, rendered his name immortal by the discovery of the secret of curing and pickling herrings, which he might probably have learned from the people of Yarmouth, and other parts of England, where herrings were not only salted and dried for *red-herrings*, but salted and barrelled up wet, at different times, from the year 1306 to 1360. Yarmouth has indeed been long famous for its herring-

herring-fair, which was regulated by an act, commonly called the ſtatute of *herrings*, in the thirty-firſt year of Edward III. He adds, that the emperor Charles V. coming to the Low Countries, made a journey to the iſle of Bier Uliet, with the queen of Hungary, on purpoſe to view the tomb of this firſt barreller of *herring*.

The Dutch begin their *herring-fiſhery* on the twenty-fourth of June, and employ no leſs than ten or eleven hundred veſſels therein. Theſe veſſels are a kind of barks called *boſſes*, carrying from forty-five to ſixty ton, and two or three ſmall cannon.

Before the eſtabliſhment of the Society of the Free Britiſh *Fiſhery*, the number of Dutch veſſels employed in this *fiſhery* was more conſiderable, and amounted to fifteen hundred or two thouſand.

None of them are allowed to ſtir out of port without a convoy, unleſs there be enough of them together, to make eighteen or twenty pieces of cannon; in which caſe they are allowed to go in company. Before they ſet out, they make a verbal convention; which has the ſame force, as if it were in writing.

Theſe regulations of the admiralty of Holland are partly followed by the French, and other nations; and partly improved and augmented with new ones; as, that no ſiſher ſhall caſt his net within an hundred fathoms of another boat; that while the nets are caſt, a light ſhall be kept on the hind part of the veſſel; that when a boat is by any accident obliged to leave off fiſhing, the light ſhall be caſt into the ſea; that when the greater part of a fleet leaves off fiſhing, and caſts anchor, the reſt ſhall do the ſame, &c.

By the act for encouraging the Britiſh white *herring-fiſhery*, in 1750, it is required, that the buſſes employed in this *fiſhery*, entitled to the bounty of 30*s.* per ton, ſhall be decked veſſels, built in Great Britain, after the commencement of the act; and that each of them ſhall carry twelve Winchester buſhels of ſalt, for every laſt of fiſh which ſuch veſſel is capable of holding, and as many more new barrels as ſuch a ſhip is capable of carrying, and two fleets of tanned nets; i. e. every veſſel of twenty tons ſhall have one fleet of nets, each thirty yards full on the rope, and ſeventeen fathoms deep, and others in proportion; and be provided with one other fleet of fifty like nets, on board a jagger or tender, which is to attend the ſaid *fiſhery*. Every ſuch buſs properly manned and furniſhed, ſhall proceed either to Broſſey's Sound in Shetland, and be at the rendezvous of the ſaid *fiſhery* there, on or before the eleventh day of June, but ſhall not ſhoot their net till the thirteenth, and ſhall continue following the ſhoal and fiſhing, as they move ſouthward, to the firſt of October; or to Campbeltown in Argyleſhire, and be at the rendezvous of the ſaid *fiſheries* on or before the firſt day of December, unleſs they ſhall have ſooner completed their loading of fiſh. For other regulations of the *herring-fiſhery*, ſee HERRING.

The manner of fiſhing has nothing particular in it. The nets wherein the fiſh is drawn, ſhould, regularly, have their meſhes an inch ſquare, that none of the leſſer fry may be taken.

The commerce of *herring*, both white, i. e. pickled, and red, is very conſiderable; but there are ſo many different ſorts, prepared in ſuch different ways, and different places, that it is hard to ſay any thing preciſe thereupon.

The white *herrings* cured by the Dutch are in the greateſt repute: they are diſtinguiſhed into four kinds, according to their ſizes. The goodneſs of this commodity conſiſts in its being fat, fleſhy, firm, white, ſalted the ſame day it is taken, and with good ſalt, and well barrelled.

The Iriſh *herring* are the next in value after thoſe of Holland; and principally thoſe of Dublin, which are ſcarce inferior to the beſt *herring* of Rotterdam or Enkuyſen. The Scotch *herring* is not ſo well prepared, gutted, ſalted, nor barrelled, as the Dutch; and yet its taſte is excellent, that of thoſe caught on the weſtern coaſt eſpecially; nor is it to be doubted, but that if the Scots were as careful in theſe circumſtances as their neighbours, their *herring* would be the beſt in the world. The *herring* fiſhed in England is inconſiderable; the fiſh being too dry for the market. However, at Yarmouth and Looſtoff they take and cure about 50,000 barrels of *red-herrings* in a year; and very large quantities are alſo caught at the mouth of the Thames by the fiſhing ſmacks of London, Folkſtone, Dover, Sandwich, &c. for the London markets, and near the ſea-coaſt of Kent and Suſſex for general conſumption.

Curing and preparing herring. 1. For *white* or *pickled herring*: as ſoon as the *herring* are taken out of the ſea, one of the crew, appointed for this office, cuts them open, and takes out the guts, and every thing but the milts and roes, which are always to be left in the body of the fiſh. Then waſhing them in freſh water, they are left the ſpace of twelve or fifteen hours in a tub full of ſtrong brine made of freſh water, and ſea ſalt.

When they are taken out, they *drain* them; and when well drained, put them up in barrels; taking care to diſpoſe and range them evenly, in rows, or layers, preſſing them well down, and ſtrewing a layer of ſalt both at top and bottom.

When the barrel is full, they ſtop it up very cloſe, that no air may get in, nor any brine out; either of which is very prejudicial to the fiſh.

The Dutch after opening and gutting the *herrings*, cure and ſalt them by lining or rubbing them inſide with ſalt; they are then packed, with handfuls of ſalt between each row, and ſtopped up cloſe.

2. For *red-herrings*: the fiſh being caught, they proceed to waſh, gut, and lay them in brine, as for *pickled-herring*; only they let them lie double the time in brine, viz. twenty-four hours; inaſmuch as they are to take all their ſalt here, whereas the other kind takes half its ſalt in the barrel.

When the *herrings* are taken out of the brine, they ſplit them, i. e. ſtring them by the head on little wooden ſpits, and thus hang them in a kind of chimney, made for the purpoſe: and when the chimney is as full as it will hold, which leſs than ten or twelve thouſand fiſhes effect, they make a little fire underneath of bruſh-wood, which yields a deal of ſmoke, but no flame.

Here the *herrings* remain, till ſufficiently ſmoked and dried; which ordinarily is in twenty-four hours. Then they are taken down, and barrelled up for keeping.

Their goodneſs conſiſts in being large, freſh, fat, oily, ſoft, and pliable; their outſide of a yellow, golden colour; their having roes, or milt, within them, and being well ſalted and barrelled. See HERRING.

FISHERY, *lobſter*. *Lobſters* are taken along the Britiſh channel, and on the coaſt of Norway, whence they are brought to London for ſale; and alſo in the firth of Edinburgh, and on the coaſt of Northumberland.

By 10 and 11 W. III. cap. 24. no *lobſter* is to be taken under eight inches in length, from the peak of the noſe to the end of the middle fin of the tail; and by 9 G. II. cap. 33. no *lobſters* are to be taken on the coaſt of Scotland from the firſt of June to the firſt of September.

FISHERY, *mackrel*. The *mackrel* is a ſalt-water fiſh, without ſcales. Its body is round, and fleſhy; terminating almoſt in a point, at each extreme.

Some perſons well ſkilled in the naval architecture, hold its figure the moſt commodious for ſwimming of all others, and propoſe it as a model for the building of ſhips.

It is ordinarily about a foot long; when in the water, it appears yellow, and when out of it, of a ſilver white, excepting four ſtreaks, or ſpeckles, of a deep blue, on the back and ſides. See MACKREL.

The *mackrel* is a ſummer fiſh of paſſage, found in large ſhoals, in divers parts of the ocean, not far north; but eſpecially on the French and Engliſh coaſts.

The fiſhing is uſually in the months of April, May, and June, and even July, according to the place. They enter the Engliſh channel in April, and proceed up to the ſtreights of Dover, as the ſummer advances; ſo that by June they are on the coaſts of Cornwall, Suſſex, Normandy, Picardy, &c. where the *fiſhery* is moſt conſiderable. They are an excellent food, freſh; and not to be deſpiſed, when well prepared, pickled, and put up in barrels: a method of preſerving them chiefly uſed in Cornwall.

Naturaliſts have obſerved, that the water wherein *mackrel* has been boiled, often yields a light, after ſtirring it a little. See FIRE, and *Luminouſneſs of the* SEA.

The fiſh is taken two ways; either with a line, or nets: the latter is the more conſiderable, and is uſually performed in the night-time. The rules obſerved in the fiſhing for *mackrel* are much the ſame as thoſe already mentioned in the *fiſhery* of herrings.

There are two ways of pickling them: the firſt is, by opening and gutting them, and filling the belly with ſalt, crammed in as hard as poſſible with a ſtick; which done they range them in ſtrata or rows, at the bottom of the veſſel, ſtrewing ſalt between the layers.

In the ſecond way, they put them immediately into tubs full of brine, made of freſh water and ſalt; and leave them to ſteep, till they have imbibed ſalt enough to make them keep; after which they are taken out, and barrelled up, taking care to preſs them cloſe down.

Mackrel are not cured or exported as merchandize, except a few by the Yarmouth and Looſtoff merchants, but are generally conſumed at home; eſpecially in the city of London, and the ſea-ports between the Thames and Yarmouth, eaſt, and the Land's end of Cornwall, weſt.

FISHERY, *oyſter*, is principally carried on at Colcheſter, in Eſſex; Feverſham and Milton, in Kent; the Iſle of Wight; the Swales of the Medway; and Tenby, on the coaſt of Wales. From Feverſham, and adjacent parts, the Dutch have ſometimes loaded a hundred large boys with *oyſters*

in

id a year. They are also taken in great quantities near Portsmouth, and in all the creeks and rivers between Southampton and Chichester; many of which are carried about by sea to London and to Colchester, to be fed in the pits about Wavenhoe, and other places. See OYSTER.

FISHERY, *pearl*. See PEARL *fishery*.

FISHERY, *pilchard*. The *pilchard* is a small salt-water fish, bigger than the anchovy, but less than the herring, which in other respects it resembles. Its head is yellow; its belly white; and its back a sea-green. It eats admirably, fresh, or lightly salted. See PILCHARD.

There are certain seasons for fishing the *pilchard*; which, like the herring and anchovy, is a fish of passage; and its arrival is indicated by similar signs with that of the herrings. They are prepared and salted much as the anchovy is; with this difference, that the head is cut off the latter; but the *pilchard* were distinguishable from the anchovy, even though its head were off likewise; the *pilchard* having a very flat back, and the anchovy a round one.

The chief *pilchard fisheries* are along the coasts of Dalmatia, to the south of the island Ilica; on the coasts of Bretagne, from Belle Island as far as Brest; and along the coasts of Cornwall and Devonshire.

It is a saying of the Cornish men, with regard to the *pilchard*, that it is the least fish in size, most in number, and greatest in gain, of any they take out of the sea. This observation is amply confirmed by Dr. Borlase's account of this *fishery*; for besides the great number of persons employed by it, the poor are fed with the offals of the captures, the land with the refuse of the fish and salt, the merchant finds the gains of custom-house and commerce, and the fisherman the gains of the fish. The usual produce of the number of hogsheads exported each year, for ten years, from 1747 to 1756, when the four ports of Fowey, Falmouth, Penzance, and St. Ives, amounted to 29,795 hogsheads. Every hogshead for ten years last past, together with the bounty allowed for each hogshead exported, and the oil made out of each, has amounted, one year with another, at an average, to the price of 1*l*. 13*s*. and 3*d*: so that the cash paid for *pilchard* exported has, at a medium, annually amounted to the sum of 49,532*l*. 16*s*. The number taken at one shooting out of the nets is amazingly great. In 1767, there were at one time included in St. Ives's bay 7000 hogsheads, each hogshead containing 35,000 fish; in all 245,000,000.

That on the coasts of Dalmatia is so plentiful, that it not only furnishes all Greece, but a great part of Italy. That on the coasts of Bretagne employs yearly above three hundred sloops, and most of the seamen of the country.

The fish caught on our own coasts, though bigger, are not so much valued, as those on the coasts of France; owing principally to their not being so thoroughly cured. The season is from June to September.

The *pilchards* naturally follow the light; and will gather about a boat that bears a light in the night time; which contributes much to the facility of the *fishery*.

On the coasts of France they make use of the roes of cod-fish, as a bait; which, thrown into the sea, makes them rise from the bottom, and run into the nets, placed for that purpose.

On our coasts, there are persons, called in Cornwall *huers*, posted ashore, who, spying by the colour of the water where the shoals are, make signs to the boats, to get among them, to cast their nets.

When taken, the fish are brought to a warehouse on shore, where they are laid up in broad piles, supported by backs and sides.

As they pile them, they salt them with bay-salt; in which they lie soaking twenty or thirty days, and discharge a great quantity of blood, with dirty pickle, and bittern; which last draws much of the oil from the fish, to the great loss of the owners. When taken out of the pile, there remains a quantity of salt, blood, scales, &c. at bottom, which, with fresh salt, serves for another pile.

They now proceed to wash them in sea-water to clear off the dirt and blood: and when dry, they put them up in barrels, and press them hard down to squeeze out the oil, which issues away at a hole in the bottom of the cask; and in this state they are fit for sale, or use.

FISHERY, *salmon*. The *salmon* is a northern fish, being unknown in the Mediterranean sea, and other warm climates, and, according to some, breeds in the sea; but the opinion of others seems better warranted, that it breeds in the clear sandy parts of rivers remote from their mouths. They commonly spawn in November; and when they have found a place fit for the purpose the male and female unite in forming a proper receptacle for it in the sand or gravel, about the depth of eighteen inches; in this the female deposits her spawn, and the male his milt, which they cover carefully as it is said, with their tails; for after spawning they are observed to have no fish on that part. The spawn lies buried till the spring. The milter and spawner, having performed their office, betake themselves to the sea; and if their return be prevented by weirs, or the like, they become sick, lean, and are then called *kipper*, pine away, and die in two years time. If they spawn in the mean time, the produce is a diminutive *salmon*, called *shegger*, which will never arrive at the natural bulk; it being the sea that makes them grow big, and the rivers fat. The female is distinguished from the male, in that its nose is longer, and more hooked, its scales not so bright, and its body speckled over with dark brown spots, its belly flatter, and its flesh not so red; more dry, and less delicious to the taste. In spawning time, when they repair from the sea up to the rivers, scarce any thing can stop their progress. Many have been them leap up cataracts and precipices, many yards high. See SALMON.

When the *salmon* first enter the fresh water, they have a number of insects, the *lernea salmonea* of Linnæus, adhering to them, especially above the gills, which are signs that the fish is in high season; these die and drop off soon after the *salmon* have left the sea. About the latter end of March, the spawn begins to exclude the young, which gradually increase to the length of four or five inches, and are then termed smelts or smouts; and about the beginning of May the Tweed, &c. is full of them; but they are soon hurried away to the sea. About the middle of June the earliest of the fry begin to drop, as it were, into the river again from the sea, being about twelve, fourteen, or fifteen inches, and they gradually increase in number and size till about the end of July; (at Berwick the fish in this stage is called gilse) when they again lessen in number, and increase in size, some being six, seven, eight, or nine pounds in weight.

The chief *salmon fisheries* in Europe are along the coasts of England, Scotland, and Ireland. The fishing usually begins about the first of January, and ends by the last of September. It is performed with nets, in the places where the rivers empty themselves into the sea, and along the sea-coasts thereabout. The fish are seen to crowd thither frequently in shoals from all parts, in search of the fresh water; they also fish for them higher up in the rivers; sometimes with nets, and sometimes with a kind of forks, or weirs, made for the purpose, with iron grates therein, so disposed, as that the fish, in going up the river, open them with their head; but are no sooner entered than the gate clops to. Thus the *salmon* are included as in a reservoir, where it is easy to take them. In some places they fish for *salmon* in the night time, by the light of torches, or kindled straw. The fishermen watch when the fish draws towards the light, whereof he is naturally a great lover, and strikes him with a peck, or lister. In some parts of Scotland, it is said, they ride a fishing up the rivers, and when they spy them in the shallow parts, shoot them with fire-arms.

Salmon form, in several countries, a great article of commerce: being cured in different ways, by salting, pickling, and drying. There are stationary *fisheries* in Iceland, Norway, and the Baltic; but those at Coleraine in Ireland, at Berwick in Great Britain, and in some of the rivers of Scotland, are the most considerable. The capture in the Tweed near Berwick, above the mouth of July, is prodigious; a boat load, and sometimes near two, is taken in a tide; and it is common to take from fifty to a hundred fish at one hawl. At this time the coopers in Berwick begin to salt both *salmon* and gilses in pipes, and other large vessels, and then barrel them to send abroad. The *salmon* barrel holds above forty-two gallons, wine measure. Most of the *salmon* taken before April is sent fresh to London; and that which they fail to send is boiled, pickled, and kitted. Fresh *salmon* has also been sent to London in the latter end of September; but then the fish are full of large roes, very thin bellied, and are esteemed neither palatable nor wholesome. In the month of July a tide of fresh *salmon* of eighteen pounds ten ounces and a half, has been sold at Berwick for eight pence; but the more common price is between sixteen pence, and two shillings and sixpence. The season for fishing in the Tweed begins the thirteenth of November, though the fishermen work very little till after Christmas, and ends on Michaelmas day. There are on this river forty-one considerable fisheries, besides others of less value, rented for near 5400*l*. per annum.

Scotland possesses also great numbers of fine *fisheries* on both sides of that kingdom. The *salmon* are cured in the same manner as at Berwick; and a great quantity is sent to London in the spring; but after that time the adventurer begins to barrel and export them to foreign countries; though the demand for them is much abated of late

late years. They have alſo in Scotland a great deal of *ſalmon*, ſalted in the common way, which after ſoaking in brine for a competent time, is well preſſed, and then dried in ſmoke: this is called *kipper*, is chiefly made for home conſumption, and if properly cured and prepared, is reckoned very delicious food. The north of Ireland abounds with this fiſh; the moſt conſiderable *fiſhery* is at Cranna, about a mile and a half from Coleraine, rented, in 1754, for 620*l.* a year. It is ſituated on the river Bann, where they fiſh with nets eighteen ſcore yards long, and are continually drawing night and day through the whole ſeaſon, which laſts about four months, 4 eight hundred and forty fiſh have been taken at a ſingle draught. There is alſo a weir on the river, which takes the fiſh that eſcape the nets. In 1760, three hundred and twenty tons were taken in the Cranna *fiſhery*. The *ſalmon* are cured in this manner: they are firſt ſplit, and the guts and gills, and many of the bones, are taken out, and then rubbed with fine ſalt; and after lying in pickle in large tubs for ſix weeks, are packed up with layers of courſe brown Spaniſh ſalt in caſks, ſix of which make a ton. Theſe are exported to Leghorn and Venice, &c. at the price of twelve or thirteen pounds a ton. Pennant's Brit. Zool. vol. iii. p. 284. 294.

The ſtat. 4 and 5 Anne, cap. 21. was made for the increaſe and preſervation of *ſalmon* in the rivers in the counties of Southampton and Wilts, requiring that no *ſalmon* be taken between the firſt of Auguſt, and twelfth of November, or under ſize, &c. And by 1 Geo. I. cap. 18. *ſalmon* taken in the rivers Severn, Dee, Wye, Were, Ouſe, &c. are to be eighteen inches long, at leaſt; or the perſons catching them ſhall forfeit 5*l.* And by 30 Geo. II. cap. 21. no *ſalmon* is to be caught in the rivers Thames and Medway between the eleventh of November and twenty-fourth of Auguſt, or to be of leſs weight than ſix pounds.

Salmon is alſo fiſhed for in rivers, after the manner of trout, with a line and hook. He bites beſt in the afternoon, about three in May, June, July, and Auguſt, the water being clear, and a little breeze of wind ſtirring; eſpecially if the wind and ſtream ſet contrary ways. The *ſalmon* is caught like a trout, with worm, fly, and minim; and eſpecially the garden-worm, if well ſcoured, and kept twenty days in moſs. The *ſalmon* never ſtays long in a place, but is continually ſhifting to be as near the ſpring-head as poſſible, and ſwimming generally in the deepeſt and broadeſt parts of the rivers, near the ground. Put two or three garden-worms well ſcoured on your hook at once, as if you were baiting for trout; and be ſure to give him time to gorge his bait, before you ſtrike. Some uſe a wire-ring on the top of the rod, through which the line may be let run to any length at pleaſure, by a reel near the hand.

FISHERY, *ſturgeon*. The *ſturgeon* is a large ſea-fiſh, which at its ſeaſon runs up the rivers; having a ſharp-pointed ſnout, a flat belly, and bluiſh back. *Sturgeons*, as well as whales, are reckoned among the number of ROYAL *fiſh*. There are *ſturgeons* of all ſizes; and we even read of ſome twenty feet long; but thoſe of the middle ſize are reckoned the beſt; though ſome prefer the ſmaller. See STURGEON.

It is of the roe or eggs of this fiſh that the CAVIAR, or kavia, ſo much prized by the Italians, &c. is prepared.

Sturgeon, when freſh, eats deliciouſly. To make it keep, they ſalt or pickle it in large pieces, and put them up in cags, from twenty-five to fifty pounds.

The greateſt *ſturgeon fiſhery* in the world is in the mouth of the Volga, in the Caſpian ſea; where the Muſcovites find employment for a great number of men. We have lately had a conſiderable ſupply of *ſturgeon* from North America, which rivals that of the Baltic.

They are not caught in nets but in a kind of incloſure, formed by huge ſtakes, diſpoſed in triangles, repreſenting the letter Z, ſeveral times repeated. Theſe kinds of *fiſheries* are open on the ſide towards the ſea, and cloſe on the other; by which means the fiſh, aſcending in its ſeaſon up the river, embarraſſes itſelf in theſe narrow, angular retreats; and, not being able to turn itſelf, to go back again, on account of its bulk, is eaſily ſtruck, and killed with a ſort of harping-iron. They are alſo taken, during ſummer, in the lakes Priſchechaff and Curiſchhaff, near Pillau, in large nets, made of ſmall cord; the adjacent ſhores are formed into diſtricts, and farmed out to companies of fiſhermen; ſome of which are rented for ſix thouſand guilders, or near 300*l.* *per annum*.

The chief object of this *fiſhery* is the roe or ſpawn, which is a commodity as much uſed in Muſcovy as butter in Holland; and there are ſome *ſturgeons* that furniſh each four hundred pounds thereof. It is only the leſſer and younger *ſturgeon* that they pickle for eating.

FISHERY, *turbot*. See TURBOT.

FISHERY, *whale*, or *Greenland* FISHERY. This huge fiſh, we have elſewhere obſerved, is chiefly caught in the North ſea. The largeſt ſort are found about Spitzbergen, ſome of them being three two hundred feet in length. Thoſe on the coaſts of America are about ninety, or a hundred; and thoſe on the coaſts of Guyenne, and the Mediterranean, are the ſmalleſt of all.

The firſt perſons that ſeem to have been employed in the *whale-fiſhery* were the Norwegians; probably ſoon after their diſcovery of Greenland, about the year 877; for we find, that king Alfred received information from Othher, a Norwegian, in 887 or 890, that the Norwegians were employed in this *fiſhery*. He tells the king, that he ſailed along the Norway coaſt, as far north as the whale-hunters commonly uſe to travel; but it ſeems that all knowledge of this gainful employ was loſt, at leaſt in this country, for almoſt ſeven centuries. The Biſcayners were alſo concerned in it, for the ſake not only of the oil, but alſo of the whale-bone, before the Engliſh; for, though their north-eaſt diſcoveries in 1553 had pointed out the way to the *whale-fiſhery* at Spitzbergen, they were ſo ignorant of the buſineſs in 1575, as to be under a neceſſity of procuring information and aſſiſtance from Biſcay for this purpoſe. The firſt mention that occurs in the Engliſh hiſtory of whale-fins, or whale-bone is in 1593, when eight hundred fins, part of the cargo of ſome Biſcay ſhips, that had been wrecked three years before, were brought to England from the bay of St. Laurence in America by an Engliſh ſhip; previous to which time, the ladies ſtays, as Mr Anderſon obſerves, muſt have been made of ſplit or ſome other tough and pliant wood; the *whale-fiſhery* being carried on for the ſake of the oil long before the diſcovery of the uſe of the whale-bone, which was firſt brought to England, with the blubber or oil, in 1617. The Engliſh having been accuſtomed to the Northern ſeas, by their repeated trials for a north-weſt and north-eaſt paſſage to China, in 1598 commenced their *fiſhery* for *whales* at or near Spitzbergen, where thoſe animals reſort in a greater numbers than any where elſe. But the firſt Engliſh voyage for the purpoſe of killing *whales* was undertaken by the Ruſſian company in 1611, who ſent two ſhips thither, with ſix Biſcayners, expert in the buſineſs; the ſhips were loſt, though their men and boats, &c. were ſaved by a ſhip of Hull, then at Spitzbergen. In 1618, the Eaſt-India adventurers joined ſtock with the Ruſſian company for purſuing the *whale-fiſhery*, and fitted out thirteen ſhips, but the voyage proved unſucceſsful. The manner of managing the whale fiſhing both by the Engliſh and Dutch was then quite different from the preſent mode; the whales, having never been diſturbed, reſorted to the bays near the ſhore, ſo that their blubber was eaſily landed at Spitzbergen, where they erected cookeries, i. e. coppers, &c. for boiling their oil; and theſe they left ſtanding from year to year, and only brought home the purified oil, and the whale-bone. The Engliſh, having been the firſt in that *fiſhery*, kept poſſeſſion of the beſt bays; the Hollanders, coming later, were obliged to find bays farther to the North; the Danes, who came later into this trade than the Dutch, got in between the Engliſh and Dutch; the Hamburghers came after the Danes, and after them came the French, and alſo the Biſcayners, the moſt ancient whale fiſhers in Europe, except the Norwegians, and purſued the ſame method. But, ſince thoſe times, the whales are leſs frequent in the bays, and are commonly among the openings of the ice farther from the land; ſo that the blubber is now cut from the whales, after they are killed, in the manner deſcribed in the ſequel of this article, and brought home to be boiled and purified, and the whale-fins are alſo to be cleaned at home. The latter method of fiſhing, being dangerous to ſhipping, diſcouraged our Engliſh adventurers who traded in a company; ſo that they ſoon after, viz. in 1619, relinquiſhed the *fiſhery*. Some private adventurers proſecuted the trade with various ſucceſs in 1621, 1622, and 1623, when they were moleſted by the Dutch, who were then ſuperior in number of ſhips, and had the prince of Orange's commiſſion; for in 1622, the Dutch, for preventing of diſturbance in their *whale fiſhery*, had erected an excluſive company, who, by their own power, might protect it; however, the *fiſhery* was laid open, in 1643, to all the inhabitants of the ſeven provinces. As to the claims which different European nations have alledged in favour of a monopoly of the *whale-fiſhery* at Spitzbergen, it has been urged by the Engliſh, that they were the firſt diſcoverers, by Sir Hugh Willoughby, in 1553; by the Dutch, who deny his having been ſo far north as Spitzbergen, and maintain their having firſt diſcovered it in 1596; by the Danes, that Spitzbergen is a part of Old Greenland, poſſeſſed in early times by them. But all nations have now wiſely given up their excluſive pretenſions, and that part of the world remains now alike free to all nations

for this *fishery*. In 1676, king Charles I. confirmed, by his proclamation, the Greenland *whale-fishery* fold to the Ruffia company, who foon relinquifhed it. In 1672 an attempt was made for reviving this *fishery*, when an act was paffed for the encouragement of it; and this act was continued in 1690, but without any great effect. A corporation was eftablifhed by act of parliament, in 1693, for carrying on this *fishery*, called the Greenland company.

In 1725 the Englifh South-fea company revived this trade, but, after great lofs, were obliged to difcontinue it in 1733. At this time a bounty of 20s. per ton was granted by parliament to Britifh fhips of two hundred tons and upwards, fitted out for the *whale-fishery*, which bounty was not only continued in 1740, but an additional bounty of 10s. per ton was granted during the war with Spain, in which we were then engaged; and in 1749, a further bounty or allowance of 20s. over and above that of 1733, was granted to all Britifh whale-fifhing fhips, and extended to fhips of the Britifh American colonies; and in 1755 this bounty was extended to fhips under two hundred tons burthen; and, as a further encouragement to this *fishery* foreign proteftants, ferving three years in it, were naturalized on certain conditions. See Huckluyt's Coll. Voyages, and Anderfon's Hiftory of Commerce.

But, notwithftanding the great importance and numerous advantages of this trade to England, and the encouragement which the legiflature has given it, the Dutch have carried it on with much greater fuccefs than the Englifh; and it is now efteemed one of the principal branches of their flourifhing trade. The chief merchants of the feveral provinces affociate themfelves into a body for carrying it on, and fend every year a great fleet of veffels to the North feas for that purpofe. They attempted to make their firft eftablifhments in Greenland; but not fucceeding, they have fince fixed their *fishery* about the weftern coaft of Spitzbergen, from the latitude of 76 deg. 40 min. to 80 deg. and from eaft to weft about eighty-nine leagues.

To give fome idea of the manner and importance of this trade, we fhall here fubjoin the difcipline of a long time obferved in the *whale-fishery*; the method of fifhing; the cargo and equipage of a veffel; and the produce thereof.

The difcipline is fubjected by a ftanding regulation, containing of twelve articles; the principal whereof are:

That in cafe a fifhing-veffel be fhipwrecked, and the captain and crew faved, the next veffel they meet fhall take them in; and alfo fecond veffel take half of them from the firft; but that no veffel fhall be obliged to take any of the loading of a veffel fhipwrecked; that as to the effects of a fhipwrecked veffel, which are abfolutely relinquifhed, and which another captain fhall find, and take up, upon his arrival in Holland, he fhall account for one half of them to the proprietors of the fhipwrecked veffel, clear of all expences; that, if the crew fubject a fhipwrecked veffel, they fhall have no claim to any of the effects faved, but the whole fhall go to the proprietor; but if they be prefent when the effects are faved, and affift therein, they fhall have one fourth thereof; that if a perfon kill a fifh on the ice, it fhall be reputed his own, fo long as he leaves any perfon with it; but the minute he leaves it, it becomes the due of the firft captain that comes that way: but alfo, if a fifh be tied to an anchor, or a rope faftened to the fhore, it fhall remain to its firft proprietor, though he leave it alone; that if any perfon be wounded or lamed in the fervice, the commiffioners of the *fishery* undertake to procure him a reafonable fatisfaction; to which the whole fleet fhall contribute.

Befides this general regulation, to the obfervance of which all the captains, pilots, and matters of veffels, are obliged to fwear, before they put to fea, there is alfo a particular one for each fhip's crew, which they are all fworn to exactly in prefence of one of the commiffioners, who goes aboard every fhip, to receive the oath. This regulation is a kind of charter-party, importing, that they will attend prayers morning and evening, on pain of an amercement, at the diferetion of the captain; that they will not get drunk, nor draw their knives, on forfeiture of half their wages; nor fight, on forfeiture of the whole; that no one fhall lay wagers on the good or ill fuccefs of the fifhing, nor buy or fell, on thefe conditions, to eafe nor take one fe marre fifh, on penalty of twenty-five florins; that they will be contented with the provifions allowed them; and that they will never light any candle, or match, by night or day, without the captain's leave, on the like penalty.

After the reading of this regulation, the crew are all called, to receive the cuftomary gratuity before their feeting out, with an affurance of another fum at their return, in proportion to the fuccefs of the fifhing.

The captain, on this occafion, receives from a hundred to a hundred and fifty florins; the pilot from forty to fixty; each harpooner from forty to fifty florins; the other officers from twenty-fix to thirty-fix florins; the elder failors twenty; and the younger twelve.

The fleet, which confifts moftly of fhips, from two to three hundred tons, and from thirty-fix men to forty-two, ufually fets fail about the beginning of April, and takes its courfe by the iles of Iceland, from 60 to 62 degrees of latitude; after which, leaving them to the weft, it fteers northward, through 73, 74, and 75 deg. of latitude, where they begin to find the ice.

It is among thefe huge heaps of ice, wherewith the whole quarter is filled, that they firft begin to fpy the whales; and there moft of the veffels fix their abode for the fifhing. But as the fifh are larger and fatter the farther north they go, fome captains will venture as far as 80 or 82 deg. of north lat. Each veffel of three hundred tons has fix fhalloops; and each fhallop has fix harpooners, with five feamen to row it. To every fhallop there are feven lines, of three inches circumference; five of them in the hinder part of the veffel, and two before. The firft line; together make fix hundred fathoms, and, with the addition of the other two, eight hundred and eighty. If the *whale* dive deeper, or run farther underneath the ice than this ftint, the line muft be cut, leaft the fhallop be drawn after it.

In the Englifh *whale-fishery* every fhip has fix or feven boats; each of which has one harpooner, one boat-fteerer, one manager of the line, and four feamen to row it. In each boat there are two or three harpoons, feveral lances, and fix lines faftened together, each line being a hundred and twenty fathom long. To each harpoon-iron is faftened a ftrong ftick, about fix feet long, and a ftaff pliable line, about fix fathom long, called the fore-gauger, which is faftened to the lines in the boat. When more line is wanted, the lines of a fecond boat are faftened to thofe of the firft.

The inftrument, wherewith the *whale* is ftruck, is a *harpoon-iron*, or javelin, five or fix feet long, pointed with fteel, in a triangular fhape, like the barb of an arrow.

The harpooner, upon fight of the fifh, from one end of the fhallop where he is placed, flings the harping iron with all his might againft his back; and, if he be fo happy as to make it penetrate the fkin and fat into the flefh, he lets go the ftring faftened to the harping-iron at the end whereof is a dry gourd, which fwimming on the water, difcovers whereabout the *whale* is; for the minute he is ftruck, he plunges to the bottom, commonly fwimming againft the wind.

If the *whale* return to breathe in the air, the harpooner takes occafion to give him a frefh wound, till, fainting by the lofs of blood, the men have an opportunity of approaching him, and thrufting a long fteel lance under his gills into his breaft, and through the inteftines, foon difpatch him; and when the carcafe begins to float, they cut holes in the fins and tail, and, tying a rope in thefe holes, they tow him to the veffel, where he is faftened along the larboard fide of the fhip, floating upon his back almoft level with the fea. They then begin to take the blubber or fat, and the fins, as they are called, or *whalebone*.

In order to this, feveral men ftand upon the fifh, with a kind of iron caltons, or fhoes, to prevent their flipping; and cut off the tail, which is hoifted upon deck, and then cut out fquare pieces of blubber, weighing two or three thoufand pounds; which are hoifted on board with the capftan, where each piece is again cut into fmaller pieces, each of two or three hundred pounds weight; and thefe are thrown into the hold, and left to drain for three or four days. When all the blubber is cut from the belly of the fifh, it is turned on one fide, by means of a piece of blubber, left in the middle, called the *cant* or turning-piece; and then they cut out this fide in large pieces, called *flitches*, as before, and alfo the whale-bones with the gums, which are preferved entire, and hoifted on deck, where the blades are cut and feparated, and left till they have time to clean and fcrape them. The fifh is next turned on his back, and the blubber cut out from the back and crown bone; and laft of all they cut the blubber from the other fide, as before. They then cut out the two large jaw-bones, inverted in the underlip, which are hoifted on deck, cleanfed and feparated as the former, and thefe are placed under them to receive the oil which they difcharge; this oil belongs to the captain, and likewife the tail and fins. The carcafe is left to float, and fupplies food for Greenland birds, called mallemucks, &c. In three or four days, they hoift the pieces of blubber out of the hold, chop them, and put fmall pieces through the bung-holes into their cafks. A *whale*, the longeft blade of whofe mouth is nine or ten

ten feet, generally fills thirty butts with blubber; but one of the largeſt fiſh will fill ſeventy butts and more. A good large *whale* is valued at about 1000*l.* ſterling. A full ſhip of three hundred ton is worth, clear of all expence, at leaſt 5000*l.* There is a premium aſſigned to every perſon in the ſhip for every *whale*: the captain has three guineas; the mate, one; each harpooner, one; the ſurgeon, one; carpenter, one; cook and boat-ſteerers, half a guinea each; a common man, a crown; and each boy, half a crown. The captain and harpooners have no wages; but the captain is allowed twenty-five pounds, and the harpooners, nine guineas each. In a ſucceſsful voyage they have ſix ſhillings for every ton of oil boiled in Greenland-dock; but the reſt of the ſhip's company have monthly wages beſides the fiſh-money, but no oil-money.

Nothing now remains, but to ſail homewards, where the fat is to be boiled, and melted down into train-oil.

The *whale-fiſhery* of the Caroline iſlands is more eaſy and agreeable than that of all other places, and, beſide the great profit, affords a pleaſant ſpectacle to multitudes of people on the ſhores.

There are ten or twelve of theſe iſles diſpoſed in form of a circle, ſo that they make a ſort of port, in which the ſea is perpetually calm and pleaſant.

When a *whale* appears in this gulf, the people all get into their canoes, and rowing towards the ſea, keep between the creature and its retreat, and drive him forwards towards the iſles at the bottom of the port. They drive him in this manner before them into the ſhallows, where they plunge into the water themſelves, and ſome get ropes and chains about him, while others dart him with their ſpears. Their agility and addreſs is wonderful in this, the creature can never get away when they have once got him faſtened, but is ſoon killed, and got to the ſhore.

FISHERY, *produce of one year's whale.* To ſtate the produce, we make choice of the *fiſhery* of 1697, as being one of the greateſt, and moſt fortunate, that ever was known; to which we ſhall add that of the year 1725.

In the year 1697, there were a hundred and eighty-nine veſſels of divers nations; whereof a hundred and twenty-one were Dutch; forty-ſeven Hamburghers; two Swediſh; four Daniſh; twelve of Bremen; two of Embden; and one of Lubeck; who caught in all 1668 fiſh.

In the year 1725, there were two hundred and twenty-ſix veſſels; whereof one hundred and forty-four were Dutch, twelve Engliſh, forty-three Hamburghers, twenty-three of Bremen, two of Bergben, two of Flenſburg. Their captures were 349 fiſh.

The Dutch captures in 1697, produced	1834	puncheons
The Hamburghers —— ——	164	of blubber
The Swedes —— ——	540	
The Danes —— ——	1710	
The Bremeners —— ——	3790	
The Embdeners —— ——	68	

The Engliſh captures in 1725, produced 1000 puncheons of blubber, and 20 tuns of whale-bone.

Now, eſtimating the puncheon of blubber at thirty florins, Dutch, or 2*l.* 15*s.* Engliſh, the current price in the year 1697, the total produce of the year's *fiſhing* amounts to 175,031*l.* 10*s.* ſterling. As to fins, or *whale-bone*, ſetting them at two thouſand weight per *ton*, and an hundred weight at 4*l.* 4*s.* they will yield 165,312*l.* which, added to the former ſum, amounts to 340,943*l.* 10*s.*

Mr Anderſon in his Hiſtory of Commerce, vol. ii. p. 350. obſerves, from an account of the Dutch *whale-fiſhery* for forty ſix years, ending anno 1721, that in this time they had employed 5886 ſhips, and caught 32907 whales, which valued one with another at 500*l.* give an amount for the whole value of above 16 millions ſterling, gained out of the ſea mainly by the labour of people, deducting the expence of the wear and tear of ſhipping, the casks and the proviſions. The *whale-fiſhery* begins in May, and continues through the months of June, and July; but whether the ſhips have had good or bad ſucceſs, they muſt come away and get clear of the ice by the end of Auguſt; ſo that in the month of September is farthеſt they may be expected at home; but the more fortunate ſhips may return in June or July.

FISHES, aboard a *Ship*, are pieces of timber, convex on one ſide, and concave on the other, uſed to ſtrengthen the maſts and yards, when they begin to fail, through an extraordinary weight of ſail, or after damage in battle, or tempeſtuous weather. They both nail the *fiſh* on with iron ſpikes, and alſo *moufe* them, as they call it, that is wind ropes hard about them. There is alſo a tackle called the *fiſh*, which hangs at the end of a davit by the ſtrap of the block, in which is the runner of the *fiſh-block*; by which means the fluke of the anchor is hauled up to the ſhip's bow or *cheſs-tree*. See BLOCKS. Perhaps this tackle was called a *fiſh*, from that which the ancients called a *dolphin*, which was a pointed and ſtrong heavy piece of iron, which they uſed to heave up by a tackle to a good height, and then, when they came near enough to the enemies ſhip, let it fall at once, to break or pierce a hole through the bottom of the enemies veſſel, and ſink her.

FISH-*gig*, an inſtrument uſed to ſtrike *fiſh* at ſea, particularly dolphins. It conſiſts of a ſtaff, three or four barbed prongs, and a line faſtened to the end, to which the prongs are faſtened; to the other end is fitted a piece of lead, which ſerves to give additional force to the ſtroke, when the weapon flies, and to turn the points upwards after the *fiſh* is penetrated.

FISH-GARTH, according to Skinner, ſignifies an engine to take *fiſh*; but it ſhould rather ſeem to denote the dam or weir in a river, where theſe engines are laid and uſed.

FISH-GLUE. See ICHTHYOCOLLA and GLUE.

FISHING, the act or art of catching *fiſh*.

Right of *fiſhing* and the property of fiſh belong to the lord of the manor, when he hath the ſoil on both ſides of a river; but where a river ebbs and flows and is an arm of the ſea, they are common to all; and he who claims a privilege to himſelf muſt prove it. In the Severn, the ſoil belongs to the owners of the land on each ſide; and the ſoil of the river Thames is in the king, &c. but the *fiſhing* is common to all. There are ſeveral ſtatutes for preventing the deſtruction of the fry of fiſh; and perſons uſing nets for that purpoſe, or taking ſalmon or trout out of ſeaſon, or any fiſh under certain lengths, are liable to forfeit 20*s.* and juſtices of peace and lords of leets have power to put the acts in force. See 1 Eliz. cap. 17. 3 Jac. I. cap. 12. 30. Geo. II. cap. 21. See *Salmon* FISHERY and *Stealing of* FISH.

Fiſhing is diſtinguiſhed with regard to its inſtrument into that performed with the net for fiſh that go in ſhoals; and that with the hook, for ſolitary fiſh; which latter is properly called ANGLING.

Fiſhing, again, is diſtinguiſhed with regard to its object into that performed in ſalt water and that in freſh. The firſt practiſed for whales, herring, cod, ſalmon, pearls, muſcrel, and other ſea-fiſh. The latter practiſed for pike, trout, carp, tench, perch, dace, eels, &c.

The inſtruments principally uſed in angling or *fiſhing* with the hook, are the rod, line, hook, and fly.

The points on which the art of *fiſhing* chiefly turns are the proper ſeaſon, place, bait, and manner of application. What relates to each thereof we ſhall here give the reader in the ſeveral kinds of *fiſhing* chiefly practiſed among us.

In March, April, and September, the warmeſt days are the beſt for *fiſhing*, and the bait muſt be deep; for the *fiſh* in theſe cool months lie near the bottom. In *fly-fiſhing* it is always obſerved, that the *fiſh* will bite beſt after a ſmall ſhower of rain, that has laid down the flies upon the water without muddying it. March, April, May, and June, are the beſt months for *fly-fiſhing*, and the beſt hours are about nine in the morning, and three or four in the afternoons in a ſtill warm evening; they will bite as long as the day-light laſts, at thoſe ſeaſons when the gnats are ſeen moſt plentifully about in the air.

In the extremity of heat, when the earth is parched with drought, there is but little ſport to be expected in *fiſhing* in any water. In cold weather, when there is a white hoary froſt in the morning, the *fiſh* will not bite kindly all day, except in the evening, if that ſhould prove ſerene and warm.

Too much wind is never convenient for *fiſhing*, though a little is rather advantageous than otherwiſe. It is bad *fiſhing* about theſe-thinning time, in waters where the theep are waſhed, for the fiſh glut themſelves in ſuch a manner with what is waſhed from theſe creatures, that they will not take any bait till that ſeaſon is over.

North and eaſt winds are enemies to *fiſhing*; and it is not right to fiſh ſoon after the time of the fiſh ſpawning, for they are then lank, and have no great appetite, ſo that they do not bite readily. All fiſh have a natural foreknowledge of a ſhower of rain, and when clouds are coming on, that will fall in rain, they will not bite; the expectation of which, we have uſed to this, often diſcipoint one to the ſport by it.

The ſubterranean or underground *fiſhing* of the lake Reſtiacjumnia, has been much talked of by thoſe who have written of the Zirchnitzer ſea, of which it is a part; but on the whole it amounts to no more than this. The waters of this lake emptying themſelves through ſubterranean paſſages into another lake below, the whole body of the water, with the fiſh in it, is firſt received into a large opening, which conveys it into a ſort of ſubterra-

bean bason, in the bottom of which there are many holes, and through these the water is let out, but the fish left behind. The people of the place who know this, descend through the large hole into this subterraneous bason with torches in their hands, and as the waters run off, they seize upon the fish wherever they can catch them. This sort of *fishing* is attended with one inconvenience; for the people being obliged to stand up to the middle, more or less, in the water, the horse-leeches, which are extremely plentiful there, seize upon their legs and other parts, and are only to be got off by some person's making water upon the part; the heat and nauseous taste of the urine always making them let go their hold. Phil. Trans. N° 92.

FISHING, *white-bait*. See BAIT.

The season for taking *white-bait* is only from the first of August to the first of October. 30 Geo. II. cap. 21.

FISHING, *barbel*. See BARBEL.

No *barbel* is to be taken in the Thames or Medway under twelve inches in size, from the eye to the end of the tail, and only between the twenty-fourth of August and the twenty-first of March. 30 Geo. II. cap. 21.

FISHING, *carp*. The *carp* is generally held the queen of fresh-water fish. It is exceeding fertile, and of all others, the eel only excepted, lives longest out of water. Mr. Ray assures us, that in Holland they have a speedy way of fattening them, by hanging them up in a net in a cellar, and feeding them with white bread and milk. See the method described under CARP. They breed several times in the year; for which reason we seldom meet with male or female without either milt or spawn. Their natural place is some still water; in running waters they rarely, if ever, breed. To make them fat and large, it is a good way, when the pond is low, in April, to rake all the sides thereof with an iron rake, and sow hay-seeds thereon. By autumn there will be a crop of grass, which, coming to be overflowed as the pond rises, will be a fine feeding-place for them.

Great patience is requisite in angling for *carp*, on account of their incredible policy. They always choose to lie in the deepest places; they seldom bite in cold weather; and in hot, a man cannot be too early or too late for them. When they do bite, there is no fear of the hold. The tackle must be very strong, and it will be proper to bait the place beforehand where it is to be fished for, with a coarse paste. It may be also proper to bring the *carp* to the place intended for angling, by throwing in cow-dung and blood, or bran and blood mixed together, or some chicken guts cut small. The baits are the red-worm, in March; the cadew, in June; and the grashopper, in July, August, and September. Proper pastes may also be prepared for them; as honey and sugar, wrought together with flour, and thrown in pieces into the water some hours before they begin to angle. Honey and white crumbs of bread mixed together, also make a good paste. The following paste is much recommended: take common wheat flour and veal, or any other young meat, of each equal quantities; beat them together in a mortar till the meat is thoroughly dissolved or broke to pieces; then add about half the quantity of honey; beat it well together again, and add more flour till the whole is of a proper consistence. This has the advantage of a paste, and of an animal bait, and hangs well upon the hook, so that it seldom fails of success.

The best season for catching fish as are intended for sale is in autumn. See CARP.

FISHING, *chub*. The *chub* or *chub* is a fresh-water fish with a large head. It spawns in March, and is very strong, though inactive, yielding in a very little time after it is struck; and the larger it is the quieter. His bait is any kind of worm or fly, particularly the large yellow moth; also grains, cheese, the pith in the bone of an ox's back, &c. He affects a large bait and a variety of them at the same hook. Early in the morning angle for him with snails; but, in the heat of the day, choose some other bait, and in the afternoon, fish for him at ground or fly. See CHUB.

No *chub* is to be taken under nine inches from the eye to the end of the tail, and only between August 24th and March 21, in the river Thames and waters of Medway. 30 Geo. II. cap. 21.

FISHING, *dace* or *dare*. See DACE.

No *dace* are to be taken in the Thames or Medway under six inches from the eye to the end of the tail in size, and only between August 24th and March 21. 30 Geo. II. cap. 21.

FISHING, *eel*. See EEL.

The *fresh eel* may be caught with divers baits, particularly powdered beef, garden-worms or lobs, minnows, hens guts, fish, garbage, &c. But as they hide themselves in winter in the mud, without stirring out for six months and in the summer, they take no delight to be abroad in the day, the most proper time to take them is in the night, by fastening a line to the bank side with a hook in the water; or a line may be thrown at large, with a good store of hooks baited, and plumbed, with a float, to discover where the fine lies in the morning. A small roach does well here for a bait, the hook being laid in his mouth. For other methods of catching *eels*, see ANGLING, BUTTERS, *Eel-spear*, and SWIGGING.

No leaps or rods for *eels* are to be laid in the Thames and Medway but from April 21 to October 30; but they may be hooked for all the year. 30 Geo. II. cap. 21.

FISHING, *flounder*. The *flounder* is a flat fish or river fish, caught in April, May, June, and July, in any time of the day, in a swift stream, and sometimes also in a still deep. The best bait is red worms, wasps, and gentles. *Flounders* may be taken in the rivers Thames and Medway at any time of the year; but their size must not be less than six inches from the eye to the end of the tail. 30 Geo. II. cap. 21.

FISHING, *gudgeon*. The *gudgeon* is a small fish of a very delicious taste. It spawns three or four times in the summer-season, and feeds in streams and on gravel, fighting all kinds of flies; but is easily taken with a small red worm. *fishing* near the ground: and being a feather-mouthed fish, will not easily get off the hook when struck. The *gudgeon* may either be fished with a float, the hook being on the ground, or by hand, with a running line on the ground, without cork or float. He will bite well at wasps, gentles, and red-worms; and one may even fish for him with two or three hooks at the same time, which makes good sport. When you angle for *gudgeons*, stir up the sand or gravel with a long pole, which will make them gather to the place and bite the faster.

The season for *gudgeon fishing* in the Thames and Medway is from August 24th to March 21st. 30 Geo. II. cap. 21.

FISHING, *pearch*, or *perch*. The *pearch* or *perch* is hook-backed, not unlike a hog, armed with stiff prickles, and his sides with dry thick scales: he is voracious, and will venture on his own kind even with greater courage than the pike. He seldom grows much above a foot long. He spawns in February or March, and bites best when the spring is far spent. The proper baits are the bradd-ling, minnow, and small frog; as also the lob-worm, bob, oak-worm, gentle, wasp, and cad-bait. The minnow yields the best sport, which is to be alive, and stuck on the hook through the upper-lip, or back-fin, and kept swimming about mid water. If the frog be used, he is to be fastened to the hook by the skin of his leg. When the fish bites, as he is none of the leather-mouthed kind, he must have time to pouch his bait. The best place to fish for him is in the turning of the water-eddy in a good gravel bottom.

No *perch* is to be taken in the Thames or Medway under six inches from the eye to the end of the tail, and only between August 24th and March 21st. 30 Geo. II. cap. 21.

FISHING, *pike*. The pike is reputed the tyrant of the fresh waters. By the common consent of naturalists, he is the longest-lived of all fishes. The larger he is found, the coarser is his flesh; and so *vice versa*. This fish never swims in shoals, but always single, being very rapacious, and preying even on his own kind. The *pike* spawns in February and March. The best sort is in rivers; the worst in meres and ponds. His ordinary food is frogs, and what fish he can lay hold on.

There are two ways of *fishing* for the *pike*; by the *ledger-bait* and the *snap-bait*. 1. The *ledger-bait* is that fixed in one certain place, and which the angler may leave behind him. Of this kind the best is some living bait, as a dace, roach, gudgeon, or a living frog. To apply it, if a fish, stick the hook through his upper-lip; then fastening it to a strong line, twelve or fourteen yards long, tie the other end of the line to some stake in the ground, or bough of a tree, near the *pike's* usual haunt, letting the line pass over the fork of a stick placed for the purpose, suspending the hook, and about a yard of line in the water, but so as that when the *pike* bites the fork may give way, and let him have line enough to go to his hold and paunch. If the bait be a frog, the arming wire is to be put in at his mouth and out at his vent, and one of his legs to be stitched or tied over the upper joint of the wire. 2. The *snapping-bait* is that which the fisher casts in, and conducts with a rod, &c. This is performed by a troll, with a winch for winding it up. At the top of the line is to be placed a ring for the line to be run through. The line, for two yards and a quarter next the hook, to be of silk double, and armed with wire the length of seven inches. On the shank of the hook is to be fastened a smooth piece of lead, so as to sink the fish bait, which is to be a gudgeon, with its head downwards. Thus disposed, the bait is to be cast up and down; and if

if you feel the fish at the hook, give him length enough to run away with the bait, and paunch it; then strike him with a smart jerk. To fish with a dead bait, use a yellow frog, dace, or roach, anointed in gum of ivy, dissolved in oil of spike, and cast it where the pike frequents. After it has lain a little while at the bottom, draw it to the top, and so up the stream, and you will quickly perceive a pike in earnest pursuit thereof. This fish bites best about three in the afternoon in clear water, with a gentle gale, from the middle of summer to the end of autumn; but in winter, all day long; and in the spring he bites best early in the morning, and late at night. Another method of *fishing* for *pike*, see under HUXING.

No *pike* or *jack* is to be taken in the Thames or Medway under twelve inches from the eye to the end of the tail, and only between August 24th and March 21st. 30 Geo. II. cap. 21.

FISHING, *roach*. The *roach*, or *rother*, is no delicate fish. Those in rivers are more valued than those in ponds, though the latter are much the larger. They spawn about the middle of May.

To angle for this fish in April, cade or worms are proper baits; as are small white snails or flies in summer. The bait is always to be under water, for this fish will not bite at top. Others use May-fly in that season with good success. In autumn, a paste must be used, made of the crumbs of white bread, moulded with a little water, laboured with the hands into a tough paste, and coloured, one very deep, with red lead. In winter, gentles are the best bait. See *paste*, the young brood of wasps, and bees slipt in blood, and the thick blood of sheep half dried, are much used in this sort of *fishing*.

In the neighbourhood of London they have a peculiar method of *fishing* for *roaches*: they take a strong cord, at the end of which is fastened a three pound weight; and a foot above the lead a packthread of twelve feet is made fast to the cord; and to the packthread, at proper distances, they add twelve strong links of hair with *roach* hooks at them, baited with a white snail or periwinkle. Then holding the cord in their hands, the biting of the fish draws the packthread, and this the cord, which gives them notice what to do. By this means they sometimes draw up half a dozen, and very commonly two or three at a draught. By 30 Geo. II. cap. 21. no *roach* is to be taken in the Thames or Medway under six inches from the eye to the end of the tail, and only between Aug. 24th and March 21.

FISHING, *smelts*. See SMELT.

By 30 Geo. II. cap. 21. no *smelt* is to be taken in the Thames or Medway less than five inches from the eye to the end of the tail, nor at any time, except from January 25th to June 1st, and those that are caught in other waters must be of the above size. 33 Geo. II.

FISHING, *soal*. See SOALE.

FISHING, *tench*. The *tench* is a fine fresh-water fish, having very small scales, but large, smooth fins, with a red circle about the eyes, and a little barb hanging at each corner of the mouth. It takes more delight among weeds in ponds than in clear rivers, and covers to feed in foul water. His slime is said to have a healing quality for wounded fish; upon which he is commonly called the *fisher physician*. When the carp, pike, &c. are hurt, it is said they find relief by rubbing themselves against the *tench*.

The season for catching this fish is in June, July, and August very early and late, or even all night, in the still part of rivers. His bait is a large red worm, at which he bites very eagerly, especially if first dipped in tar. He also delights in all sorts of pastes, made up of strong-scented oils, or with tar; or a paste of brown bread and honey; nor does he refuse the cad-worm, lob-worm, flag-worm, green gentles, cod bait, or soft boiled bread-grain.

When a number of *tench* are to be taken out of a muddy pond, the method is to take a large casting-net, well leaded, and with the meshes from the crown to a full yard and a half, not too small; for then, if the pond be deep, the fish will strike away before the net gets to the bottom. The place where the net is to be thrown into must be cleared of weeds, &c. with a rake. A bait is next to be prepared for drawing the fish together; for this purpose, put a quarter of a peck of wheat into three quarts of water, send it to an oven, and let it be well soaked; then add to it five pints of blood, and as much bran as is necessary to give it the consistence of paste; mix with it some clay, and add a quart of lob-worms chopped to pieces. Let the whole be wrought up into a stiff paste, and rolled into balls of the size of a hen's egg, and throw these into the pond in the place where the net is to be cast. Let these, and some grains, be occasionally thrown in, and the place be thus baited for several days. When the fish may be supposed to be well acquainted with the place, let a good baiting be given in the morning, and in the close of the evening let the casting-net be carefully thrown in. When the net is sunk, the mud all about is to be stirred with a long pole, with a fork at the end; the net is to lie half an hour, and the mud to be thus stirred all the time; by this means the *tench* will be raised, and will be taken by pulling out the net; but if the net were to be thrown in and taken out in the common way, there would hardly be one fish taken; for the custom of both *tench* and carp, when they are frighted, is to plunge their heads up to the eyes in the mud, and thus placed with their tails erect, the net must draw over them, without the possibility of entangling them.

FISHING, *trout*. The trout is a delicious fresh-water fish, speckled with red and yellow, coming in and going out of season with the buck, and spawning in the cold months of October and November, whereas all the other species spawn in hot summer weather. There are divers kinds of this fish, all valuable; but the best are the red and yellow *trouts*; and of these the female, distinguished by a less head and deeper body, is preferred. They are known to be in season by the bright colour of their spots, and by their large and thick backs; which last may serve also as a rule for other fish. Through the whole winter they are sick, lean, and unwholesome, and frequently lousy. As the spring comes on, deserting the still deep waters, they repair to the gravelly ground, against which they continue to rub till they get rid of their lice, which are a kind of worms with large heads. From that time they delight to be in the sharp streams, and such as are swift, where they lie in wait for minnows and May-flies. At the latter end of May they are in their prime.

The usual baits whereby the *trout* is caught are the worm, minnow, and fly, either natural or artificial. The proper worms are the brandling, lob-worm, squirrel-tail worm, which has a streak round the back, a red head, and a broad tail, cath-worm, dung-worm, and maggot or gentle, especially the three first; the brandling is commonly found in an old dunghill, or under cow-dung, or else among tanners bark; the others are found in the earth, and under large stones and flumps of trees; but whatever worms are used they are the better for keeping, which is to be done in an earthen pot, with moss, frequently changed. To take the *trout* with a ground-bait, the angler should have a light, taper rod, with a tender hazel top; and may angle with a single hair of three links, the one tied to the other, for the bottom of the line, and a line of three-haired links for the upper part: with this sort of tackle, if the sportsman has room enough, he will take the largest *trout* in any river. The angler must always keep out of sight, and the point of the rod must be down the stream. The season for *fishing* for the *trout* with the ground-bait begins in March, and the mornings and evenings are the best time of the day; but in cloudy weather the sport may be followed all day long. There must be a plummet at ten inches from the hook, which the angler must feel, always touching the ground; and this must be heavier as the stream is swifter. When the minnow is used, chuse the whitest, and that of middling size; slip the hook through his mouth, and the point and beard out at the tail, so as it may lie almost straight on the hook. Then try against the stream, whether it will turn. The tackle in this case may be stronger, for the *trout* will seize this bait as soon as it comes in sight; the upper part of the line may be of three silk and three hairs, and the lower of two of each; and the hook may be moderately large. In defect of a minnow, a small loach, or a stickle-back, may serve the turn; or for want of either, an artificial one may be made of cloth by the life, which is found every whit as good a bait as the natural one.

The most agreeable manner of *fishing* for *trout* is with the fly: the rod in this case must be light and pliable, and the line long and fine; if one hair be strong enough, as it may be made by proper skill in the angler, there will be more fish caught than when a thicker line is used; and the fly-fisher should have the wind in his back, and the sun before him. See ANGLING.

By 1 Eliz. cap. 21. no *trout* is to be taken under eight inches in length; and by stat. 24 Anne, cap. 21. *fio-trout* is not to be taken in particular rivers, creeks, or arms of the sea between June 30th, and Nov. 1st. By 30 Geo. II. cap. 21. no *trout* is to be taken in the Thames or Medway between November 11th and August 23d, or to be of less weight than one pound.

FISHING-*fly*, a bait used in angling for divers kinds of fish. The *fly* is either *natural* or *artificial*.

Natural flies are innumerable: the more usual on this occasion are the *dun-fly*, the stone or *May-fly*, the *red-fly*, the *moor-fly*, the *tawny-fly*, the *wasp-fly*, the *bumble-fly*, the *drone* and *black-fly*, the *hazle-fly*, also *caterpillars*, *cadder-*

amber-flies, *bear-flies*, &c. all which appear sooner or later, according to the forwardness or backwardness of the spring. To know the particular fly the fish most covets, when you come in the morning to the river side, beat the bushes with your rod, and take up what variety you can of all sorts of flies; try them all, and you will quickly know which are in most esteem: not but that fish will sometimes change their fly; but it is only when they have sometimes glutted themselves therewith.

There are two ways to fish with *natural flies*, either on the surface of the water, or a little underneath it.

In angling for chub, roach, or dace, move not your *natural fly* swiftly, when you see the fish make at it; but rather let it glide freely towards him with the stream; but if it be in a still and slow water, draw the fly slowly sideways by him, which will make him eagerly pursue it.

The *artificial fly* is most successfully used in blustering weather, when the waters are so troubled by the winds that the natural fly cannot be seen, nor rest upon them.

Of this *artificial fly* there are reckoned ten principal sorts.

1. The *dun-fly*, in March, made of dun-wool, and the feathers of a partridge-wing. 2. A *dun-fly*, made of black wool, and the feathers of a black drake; the body made of the first, and the wings of the latter. 3. The *stone-fly*, in April, the body made of black wool, dyed yellow under the wings and tail. 4. The *ruddy-fly*, in the beginning of May; the body made of red wool, and bound about with black silk, with the feathers of a black capon, which hang dangling on his sides next his tail. 5. The *yellow* or *greenish fly*, in June; the body made of black wool, with a yellow list on either side, and the wings taken off the wings of a buzzard, bound with black broken hemp. 6. The *moorish-fly*; the body made of dusky wool, and the wings with the blackish mail of a drake. 7. *Tawny-fly*, till the middle of June; the body made of tawny wool, the wings made contrary one against the other, of the whitish mail of a white drake. 8. The *wasp-fly*, in July, the body made of black wool, cast about with yellow silk, and the wings of drake's feathers. 9. The *stock-fly*, in the middle of July; the body made of greenish wool, cast about with the feathers of a peacock's tail, and the wings made of buzzards wings. 10. The *orchet-fly*, in August; the body made of black wool, cast about with black silk, his wings of the mail of a black drake, with a black head.

The best rules for *artificial fly-fishing* are,

1. To fish in a river somewhat disturbed with rain, or in a cloudy day, when the waters are moved by a gentle breeze; the south-wind is best; and if the wind blow high, yet not so but that you may conveniently guide your tackle, the fish will rise in plain deeps; but if the wind be small, the best angling is in swift streams.

2. Keep as far from the water-side as may be; fish down the stream, with the sun in your face, and touch not the water with your line.

3. Angle always in clear rivers with a small fly and slender wings, but in muddy places use larger.

4. When after rain the water becomes brownish, use an orange fly; in a clear day, a light-coloured fly; a dark fly for dark waters, &c.

5. Let the line be twice as long as the rod, unless the river be encumbered with trees.

6. For every sort of fly have several of the same, differing in colour, to suit with the different complexions of several waters and weathers.

7. Have a nimble eye and active hand, to strike presently with the rising of the fish, or else he will be apt to throw out the hook.

8. Let the fly fall first into the water, and not the line, which will scare the fish.

9. In slow rivers or still places, cast the fly cross over the river, and let it sink a little in the water, and draw it gently back with the current.

Salmon-flies should be made with their wings standing one behind the other, whether two or four. That fish delights in the gaudiest colours that can be; chiefly in the wings, which must be long, as well as the tail.

FISHING-*hooks* are little appendages to the line, serving to keep the hook and bait suspended at the proper depth, to discover when the fish has hold of them, &c.

Of these there are divers kinds, some made of Muscovy duck quills, which are the best for slow waters; but for strong streams, round cork, without flaws or holes, bored through with a hot iron, into which is put a quill of a fit proportion, is preferable; pare the cork to a pyramidal form, and grind it smooth.

FISHING-*hook*, a little engine of steel-wire, of a proper form to catch and retain fish.

The *fishing-hook*, in general, ought to be long in the shank, somewhat thick in the circumference, the point even and straight: let the bending be in the shank. For setting the hook on, use strong, but small silk, laying the hair on the inside of your hook; for if it be on the outside, the silk will fret and cut it asunder.

There are several sizes of these *fishing-hooks*, some big, some little; and of these some have peculiar names, as,

1. *Single-hooks*. 2. *Double-hooks*, which have two bendings, one contrary to the other. 3. *Snappers* or *gorgers*, which are hooks to whip the artificial fly upon, or to bait with the natural fly. 4. *Springers* or *spring-hooks*, a kind of double hooks, with a spring which flies open, being struck into any fish, and so keeps its mouth open.

FISHING-*line*. See *Angling*-LINE.

FISHING-*net*. See NET.

FISHING-*rod*, a long slender rod or wand, to which the line is fastened for angling.

Of these there are several sorts, as,

1. A *troller* or *trolling-rod*, which has a ring at the end of the rod for a line to go through, when it runs off a reel. 2. A *whipster* or *whipping-rod*, a top-rod that is weak in the middle, and top-heavy, but all slender and fine. 3. A *dapper*, which is a strong rod, and very light. 4. A *snapper* or *snap-rod*, that is, a strong pole, peculiarly used for the pike. 5. A *bottom-rod*, being the same as the dapper, but somewhat more pliable. 6. A *snigging* or *poking-stick*, a forked stick, having a short, strong line, with a needle, baited with a lob-worm; this is only for eels in their holes.

Fishing-rods are made of different materials and strength, according to the purposes for which they are used: in *fishing* with more than one hair, and with a silk-worm gut, red deal is reckoned the best, with hickery top, and the length of the whole rod should be about four yards; but for a small fly and single hair, the length of three yards will be sufficient, with the top of yellowish hickery, and about nine inches of whalebone, near as long as the stock, which should be of white deal. The stocks, or buts of rods, are generally of ground hazle, ash, or willow, about two or three feet long; and every joint should gradually taper to the top. Hazle tops are preferred, though some use the bamboo cane, and say it exceeds the best hazle. For ground angling, especially in muddy waters, the cane or reed is preferred for a stock; with a hazle-top, consisting of one, two, or three pieces, and a small piece of round, smooth, taper whalebone, which is whipped to the hazle with strong silk, rubbed with shoemaker's wax; the whole length of the rod being five yards, or five and a half yards. The best method of piecing hazle and bone, is first to whip the end of the hazle with thread, and to bore it with a square piece of iron of a proper size; and then make the thick end of the bone, first dipped in pitch, to go into it; after which let it be scraped, filed, and neatly whipped. However, the neatest rod may be thus made: get a thick white deal or fir-board, free from knots, and seven or eight feet long; let this be divided by a joiner into several breadths, and with his planes let him shoot them round, smooth, and taper. To one of these fasten a hazle rod, six or seven feet long, which may consist of two or three pieces; to the top of which fix a piece of yew, about two feet long, made round, taper, and smooth, and to the yew a piece of small, round, smooth whalebone, five or six inches long. The fir may be coloured by warming it at the fire, and with a feather dipped in aqua fortis, stroking it over, and chafing it into the wood, which will make it of a pure cinnamon colour.

It is found useful to have rings or eyes made of fine wire, and placed upon the rod from one end to the other, in such a manner as that when the eye is laid to one you may see through all the rest; through these rings the line is made to run, which will thus be kept in a due posture; and you must have a winch or wheel affixed to the rod about a foot above the end, by which, whenever it is proper, you may give range to the fish. See ANGLING.

FISHING-*tackle*, or those used in the several fisheries at sea, or on the coasts, are the *hulk*, *cable*, *sack*, *dagger*, *debar*, *oak-boat*, *fir-boat*, *float*, *hooker*, *Peter-boat*, *smack*, *stand-boat*, *trawler*, *trinker*, &c.

FISH-PONDS, reservoirs of water, for the breeding, feeding, and preserving of fish.

The quality of the pond, water, &c. proper for this end is scarce determinable by any certain symptom or rules; for some very promising ponds do not prove serviceable that way. One of the best indications of a breeding pond, is, when there is good store of rush and grazing about it, with gravelly shoals, such as horse-ponds usually have; and when a water takes thus to breeding, with a few milters and spawners, that is, males and females, two or three of each, a whole county may be stocked in a short time.

Eels and perch are of very good use to keep down the stock

flock of fish; for they prey much upon the spawn and fry of bred fish, and will probably destroy the superfluity of them.

As for pike, perch, tench, roach, &c. they are observed to breed almoſt in any waters, and very numerouſly; only eels never breed in ſtanding waters that are without ſprings; and in ſuch are neither found, nor increaſe, but by putting in; yet where ſprings are, they are never wanting, though not put in. And, which is moſt ſtrange of all, many ſay there is not in an eel the leaſt token of propagation, either by milt or ſpawn; ſo that how they are produced is a queſtion very myſterious. See EEL.

For *fiſh-ponds*, it is agreed, thoſe grounds are beſt which are full of ſprings and apt to be moiſt; the one breeds them well, and the other preſerves them from being ſtolen. The ſituation of the pond is alſo to be conſidered, and the nature of the currents that fall into it; likewiſe, that it be refreſhed with a little brook, or with the rain-water that falls from the adjacent hilly ground. Add, that thoſe ponds which receive the ſtale and dung of horſes, and other cattle, breed the largeſt and fatteſt fiſh.

Fiſh-ponds are not only a thing of convenience to great families, but may be made a very profitable article with the farmer, under due management. Watery and boggy land is often fit for no other uſe, and theſe are then a great improvement of it. Ponds made in dry grounds in the flat bottoms between hills, will alſo ſerve not only to ſupply the cattle with water, but the profit of the fiſh that may be bred in them, is greater than many are aware of, and comes without any labour or expence.

In making the pond, obſerve that the head be at the loweſt part of the ground; and that the trench of the flood gate or ſluice have a good ſwift fall, that it may not be long in emptying on occaſion.

The beſt way of making the head is by driving three or four rows of ſtakes about ſix feet long, and at about four feet diſtance from one another, the whole length of the pond-head: the firſt row of theſe is to be driven in four feet deep, that they may be very firm and ſecure; and if the bottom be not good, but be of a looſe ſand, ſome lime is to be added, which will harden into a ſort of ſtone. The earth dug out of the pond is to be laid between theſe ſtakes and rammed hard down. Other rows of ſtakes muſt be added behind and over theſe, and the ſpaces filled up till the whole is as high and as thick as is neceſſary. The face of it muſt be made even and ſlanting, and there muſt be a waſh left to carry off the ſuperfluous water in floods, &c.

If the pond carry ſix feet of water, it is enough; but it muſt be made eight feet deep, to receive the freſhes and rains that may fall into it.

It would alſo be advantageous to have ſhoals on the ſides for the fiſh to fun themſelves in, and lay their ſpawn on; beſide, in other places, certain holes, hollow banks, ſhelves, roots of trees, iſlands, &c. to ſerve as their reſting-places. Conſider further, whether your pond be a breeder; if ſo, never expect any large carp from thence, the greateſt of the number of ſpawn overſtocking the pond.

Carp and tench will live and thrive very well together in the ſame pond. Where pike are kept, there ſhould be roach or ſome other quick breeding fiſh to ſupply them with food.

Some think that pike and tench may be kept in the ſame pond. They imagine that pike will not feed upon tench; but they are miſtaken, for the pike is fonder of this than of almoſt any other fiſh. Ponds with clear gravelly and ſandy bottoms are uſually the beſt for breeding of fiſh, and foul water with muddy bottoms are the beſt for them to fatten in. Carp have been known to grow in one year from five to eighteen inches long in ponds where the water of the common ſewers of any town have run into it.

The ordinary growth of a carp is not above two or three inches in that time, ſo that all the exceſs is to be attributed to the fatneſs of the water of the ſewers. See CARP.

Reſerve ſome great waters for the head-quarters of the fiſh, whence you may take, or wherein you may put any quantity thereof; and take care to have ſtews, and other auxiliary waters, ſo that you may convey any part of the ſtock from one to the other, and loſe no time in the growth of the fiſh, but employ the water as you do your land, to the beſt advantage. View the grounds, and find out ſome fall between the hills as nearly flat as may be, ſo as to leave a proper current for the water: if there be any difficulty in judging of ſuch, take an opportunity after ſome ſodden rain, or the breaking up of a great ſnow in winter, and you will plainly ſee which way the ground calls, for the water will take the true fall, and run accordingly.

The condition of the place muſt determine the quantity of ground to be covered with water. For example, we may propoſe in all fifteen acres in three ponds; or eight acres in two, and no leſs; and theſe ponds ſhould be placed one above another, ſo as the point of the lower may almoſt reach the head or bank of the upper; which contrivance is no leſs beautiful than advantageous.

The head or bank, which, by ſtopping the current, is to raiſe the water, and to make a pond, muſt be built with the clay and earth taken out of the pan or hollow dug in the loweſt ground above the bank; the ſhape of the pan is to be an half-oval, whereof the flat is to come to the bank, and the longer diameter to run ſquare from it.

All *fiſh-ponds* ſhould be drawn once in three or four years, and the fiſh ſorted; if it be a breeding-pond, the ſmaller fiſh ſhould be taken out to ſtore other ponds with; and in feeding-ponds all the fiſh ſhould be kept as nearly as may be of a ſize, for the larger and ſmaller never all thrive well together.

Flounders will both thrive and breed in any pond, eſpecially in a clay pond, and will be much larger than in rivers.

Bitterns, herons, otters, water-rats, and fea-pullis, are all great deſtroyers of fiſh, and the ponds ſhould be kept as clear as poſſible of them; but the greateſt of all deſtruction in *fiſh-ponds* is occaſioned by ſroſts.

To remedy this, ſome propoſe to break the ice and lay in pipes, ſtraw, and other things, to give air to the fiſh; but all theſe fail when the ponds are foul; but when they are clean, the fiſh ſeldom ſuffer any harm, be the froſt ever ſo long, though no holes be broke in the ice. The ſtench of foul water ſeems to be the occaſion of the death of the fiſh, in this caſe of its being locked up by froſts, and not the want of air. The cleaning of ponds frequently is of great uſe as well on this as on many other occaſions; and it is done at no expence, becauſe the mud ſerving as manure to the lands, more than pays the expence of taking it out.

When the ground is boggy, and carts cannot come up to take the mud, it is beſt to cut the ponds long and narrow in form of moats, that it may be thrown out at one ſide by the labourers in clearing them; for if it require two ſides, the difference will be juſt the double price of labour.

FISSURE, FISSURA, in *Surgery*, a longitudinal fracture of a bone: or a ſolution of the continuity of a bone, whereby it is only cloven or cracked.

Fiſſures are of two kinds; the one apparent, by the Greeks called ῥαγὰς or ῥῆξις; and by the Latins, *fiſſura*; the other ſo ſmall as not to be viſible, called τριχισμὸς, or *capillary*, as reſembling a thread.

The cauſes of *fiſſures* are falls, leaps, and contuſions of the parts againſt hard bodies.

Fiſſures, eſpecially in the cranium, either happen on the part where the ſtroke was given, or on the oppoſite part: that on the oppoſite part is called *counter-fiſſure*, or *counter-cleft*, by the Greeks, ἀντιρροια, and the Latins, *retruſio*. See CONTRA-*fiſſure*.

Old men are more ſubject to *fiſſures* than young ones, becauſe their bones are drier.

Fiſſures are difficult to be diſcovered; but they are the eaſieſt cured of all fractures; though if they be not known, or be neglected, they bring on ulcers and caries, and in ſuch caſe become very dangerous, ſo that there is frequently a neceſſity of having recourſe to the ſevereſt operations.

The ſigns of a *fiſſure* of the cranium are bilious vomitings, vertigoes, fluxes of the blood at the mouth or noſe, dumbneſs, delirium, &c. If there be any *fiſſure* in the ſcull, the patient will feel a pain in the place, upon holding a ſtring between his teeth, while the ſurgeon pulls it ſtrongly.

In ſuch caſes it is frequently neceſſary to perforate the cranium, to give a vent for the blood and ſanies. See CONTUSION.

FISSURES, in the *Hiſtory of the Earth*, certain interruptions that horizontally or parallely divide the ſeveral ſtrata of which the body of our terreſtrial globe is compoſed.

FISTUCA, in *Antiquity*, an inſtrument of wood uſed in driving piles, and fitted with two handles. It was either raiſed with pullies fixed at the head of large beams, and then let fall again directly on the piles, or was wrought by the hand only.

FISTULA, in the *Ancient Muſic*, an inſtrument of the wind kind, reſembling our flute or flageolet.

The principal wind inſtruments of the ancients were the *tibia* and *fiſtula*; though how theſe were conſtituted, or wherein they differed, or how they were played on, does not at preſent appear. All we know is, that the *fiſtula* was at firſt made of reeds, and afterwards of other matters. Some had holes, ſome none; ſome again were ſing e

single pipe; others a combination of several, without the fistulæ.

FISTULA, in *Surgery*, a deep, winding, cavernous ulcer, with a narrow aperture, and opening thence into a spacious bottom, formed in the cellular membrane, and generally yielding a sharp and virulent matter.

Fistulæ differ from simple sinuses in this, that the former are callous, as well in their progress, and the latter not.

They attack all parts of the body without exception; but principally the anus, perinæum, tuberosities, thorax, &c.

The general cause of *fistulæ* is some abscess or ulcer, which, either being inveterate, or having been ill treated, comes to be callous, the orifice being at first lined or incrustated therewith, and at length the whole sinus.

In the first stage of a *fistula*, before they are become callous, the readiest way of curing them is by an incision to the bottom, whenever it can be safely done, and afterwards detergent and consolidating foam. They should then be gently prefled from the bottom towards the orifice in order to discharge the peccant matter; for which purpose a compress or small slip of plaster wrapped up in such a form should be applied to the bottom of the *fistula*, after it has been cleansed, and proper dressings have been used, and covered with tent, plaster, and bandages; and if this method fail, recourse must be had to the manual operation; because, by laying open all the sinuses of the *fistula*, proper passages are made for the discharge of the corrupted matter, and suitable remedies may be conveniently applied to the several affected parts. The ancients gave the name *fistula* to this kind of ulcers, from the resemblance they bear on account of their depth to a flute or pipe, called by the Latins *fistula*.

FISTULA *ani*, is a *fistula* formed in the anus or fundament. Of this some reckon four kinds, viz. the *incomitans*, which is open outwards, but not into the rectum; the *coecum introrsum*, which has an aperture into the rectum, but none outwards; the *complex*, which opens both ways; and the *cunniculosa*, or that with several sinuses, which discharge themselves into one common cavity, which is the fund, and, as it were, the reservoir of them all.

Others, as Wiseman, reduce *fistulæ in ano* into two classes. The first are those arising from a phyma; these are very painful, and difficult to cure, enter deep among the interstices of the muscles, and form various sinuses or sunnies; which, the more remote they are from the anus, the worse they are, because they do not allow of being cut.

The second have their origin to an internal haemorrhage, or extravasation between the coats of the rectum, and have a small perforation near the circumference of the anus, whence they yield a thin sanies or ichor without pain, which in time brings on itchings and excoriations; and the orifices at length become callous, and are sometimes closed, and sometimes open again.

Some *fistulæ*, if they do no harm by the copiousness of the flux, the stench, or the like accidents, are a benefit to nature, because they carry off cachectic humours, and ought not to be cured, but kept open. The stesh, simple *fistulæ* may be cured without danger.

The chief way is by cutting, where that may be done without damage to the muscles of the anus, which might occasion an involuntary discharge of the excrements.

The cutting is either performed with a thread or with a cutting instrument.

The method by ligature is to take a thread of silk or horse hair, and threading it in the eye of a leaden or tin probe, to introduce the end of the thread into the *fistula*, and with the fore-finger of the other hand, anointed with oil of roses, and thrust up into the anus, to lay hold of the end of the probe and draw out the thread, and then tie the two ends together as tight as the patient can well bear it; and thus by tying it afresh, somewhat tighter every day, it will cut quite through, and the *fistula* will be laid open; after that the callus must be consumed, and the ulcer healed. Mr. Pott advises the operation by incision, to be performed in the following manner: let a sharp probe-pointed knife with a narrow blade be introduced into the sinus, while the surgeon's fore-finger is in the intestine; when there is no opening in the meantime, the least degree of force will thrust the point of the knife through, and then by making one, if there be an opening already, the same probe will find and pass through it. In either case, it will be required by the degree in use, will thereby be prevented from deviating, and, being brought out by the fall finger, must necessarily divide all that is between the edge of the knife and the verge of the anus. When the operation is finished, a soft cord of fine lint must be introduced between the lips of the wound, and the rest of the ulcer dressed with the tent. He observes, in the remarks on this disease, that it is much more common than is generally imagined; and that a mere abscess or collection of matter, without *fistula* or callosity, is often mistaken for it. A total suppression of urine is a symptom frequently attendant on the formation of an abscess near the rectum and bladder; for the relief of which, recourse is often had to the catheter; but as this complaint is spasmodic, he advises evacuation and anodyne relaxation, such as venesection, gentle cathartics, semicupium, bladders of hot water applied to the pubes and perinæum, and clysters compoled of warm water, oil, and opium, as the true, safe, and rational method of relieving it.

FISTULA, in the *Lachrymals*. We have in the Lond. Med. Obf. vol. ii. p. 2-3. a case of this kind, related by Mr. Ingham: a man of thirty-five years of age hurt his testicles by a fall, a fuppuration followed, and the matter was discharged externally. After this, the swelling being reduced by means of emollient and refolvent cataplasms, a *fistula* was discovered in each epidydymis: a fine probe-director was then introduced into the sinus of the left testis, which was cut open through its whole length; after which all the indurated parts and the diseased skin were cut off, the same was done to the other testis, and a large portion of the lower part of the epidydymis was extirpated. A fuppuration came on in five or fix days, and the patient was cured by the common method of dreffing in three weeks; fo that the functions of the testes were properly executed.

FISTULA *lachrymalis* is a *fistula* in the greater canthus of the eye: this is frequently confounded with ROSE-UPS.

If in a little deep callous ulcer in the greater caruncle, or the place of the glandula lachrymalis. It usually begins with an abfcefs, called *anchilops*, which in time produces an ulcer, called *regilops*, which afterwards degenerates into a *fistula*. When preffed with the finger it yields a ftinking matter, not unlike the yolk of an egg; and the corrosive humour, finding or making itself a paffage, there enfues a perpetual oufing.

Sometimes the os ethmoides itself is corroded, and rendered carious by it, in which condition it is fuppofed to be only curable by an actual cautery; fometimes it becomes cancerous; and then Riverius directs all medicines to be laid afide.

This malady is feldom or ever cured by any other means than external and chirurgical operation; and the operator muft be guided by the various circumftances of the difeafe. If the lachrymal fac and its integuments be diftended with only a fmall degree of inflammation and thinnefs of the ftin, a fingle incifion, made with a fmall fharp round-pointed knife, and continued from the upper to the lower extent of the tumor quite down into the cavity of the eye, will fometimes be found fufficient, for the purpofe of applying proper dreffings to the bottom of the difeafed fac. Where the ftin is much ftiled up and grown thin, and difcoloured from a large quantity of matter that has long been depofited and confined in the fac, or where the integuments have burft, become callous and livid; it will be found expedient, in the firft inftance, to remove an oval piece of the integuments and fac; and, in the fecond inftance, the whole of the callous integuments, together with the upper part of the lachrymal fac, muft be cut away; by thefe means every advantage which art can procure will be obtained for the treatment of an hollow ill-conditioned *fore*. Warner, &c. on the Eye, 1775, p. 19.

Mr. Lamorier propofes to abridge the operation of the *fistula lachrymalis*, and to procure a paffage for the tears into the nofe. The os unguis is to be laid bare at the firft incifion, and pierced with a pair of ftrong, fharp-pointed and crooked forceps, and then the perforation dilated by opening the forceps. After the inflammation is over, a piece of fmall wax-candle, fhaped like a ftent, is to be introduced by the wound into the nofe, and fecured by the other dreffings. He continues the ufe of this bougie till the paffage is made callous, and out of hazard of reuniting; after which he allows the external wound to cure. Medic. Eff. Edinb.

Dr. Hunauld has communicated fome thoughts on the operation of the *fistula lachrymalis*, and propofes, that no ftent fhould be put into the perforation of the os unguis, becaufe the tears will of themfelves keep it open. Hift. Tranfa. N° 433-435. or Abr. vol. ii. p. 121, &c.

Mr. Petit confiders the canals for the tears from the *puncta lachrymalia* as a typhon, the longer leg of which is the nafal duct, and therefore thinks that a fhorter paffage made through the os unguis would not convey away the tears; for which reafon he would always have the natural paffage forced open in the *fistula lachrymalis*, and a fmall bougie kept in it till it heals. Mem. Acad. Scienc. 1734.

A French surgeon, named Anel, found out a new way, viz. by putting a probe and syringe of an inconceivable fineness through the puncta lachrymalia into the saccus lachrymalis. *See Tab.* II. *Surgery. fig.* 20.

Mr. Warner has proposed a method of clearing the obstructed lachrymal duct, by leaving in it a metal tube, and healing the external wound over it. In order to introduce the tube properly, he has contrived a kind of style fitted to it. For the description and representation of both, see his New and easy Method of applying a Tube for the Cure of the *Fistula Lachrymalis*. 4to. 1781.

The expediency of perforating the os unguis has been a subject of dispute, especially when it does not appear to be carious, known by being divested of its periosteum. But Mr. Warner observes, from his own experience, that there is no curing a disease of this kind without destroying the os unguis, at least in part, even when that bone is not denuded and carious. The necessity in breaking through this bone arises from the diseased state of the hinder part of the sack and periosteum: the os unguis is so thin as to require very little force in breaking it; a passage may be made through it into the nostril with the edge of the incision-knife, and so effectually as not to require the assistance of any other instrument besides a large probe or bougie, bent and fitted to the size and direction of the orifice, and inclining downwards into the nostril. The perforation of the os unguis is sometimes known by its cracking, and by a discharge of blood, which in a small quantity trickles down the nostril. If a trocar be used for this purpose, it should not be too much curved; otherwise it will be brought too much forwards and outwards, inclining to the nasal process of the superior maxillary bone, which is thick and strong, and cannot be broke without very great force. When the perforation is made, Mr. Warner immediately introduces a small long spunge tent through the wound into the nostril, and continues the use of the tent for ten or twelve days, or longer; together with thin and soft injections for keeping the parts clean and open wherever the wound is dressed, which is generally at first necessary to be done twice a day. When the opening through the os unguis is sufficiently confirmed, known by being able to introduce into the nostril a small bougie, or a large ductile probe, without resistance; he uses soft tents of lint for a week or ten days longer, and then dresses the wound to the bottom, sometimes with pledgets of detersive ointments, and sometimes with dry lint only, occasionally touching the sprouting and loose flesh with the lunar caustic, which he prefers to vitriol. He afterwards dresses the wound almost superficially with lint, or coratum opiolticum spread upon lint, till the parts are healed; and the cure is usually completed in five or six weeks.

Some have recommended pressure upon the integuments and subjacent lachrymal sac, by means of instruments adapted to this purpose, in incipient abscesses and dilations of these parts; but Mr. Warner observes, that he has seldom or ever found such an application of service. The best pressure in such case is that of one of the fingers applied to the inferior part of the tumor when the sac is loaded and distended: by this simple treatment, joined with purgative medicines, and a moderately cooling and astringent eye-water, the disease has been checked, and may possibly be cured. In this disease, opiates occasionally administered, evacuations by bleeding, gentle purges or clysters, and antiphlogistic medicines, joined with a proper regimen in diet, ought to be continued till the inquietude, spasms, pain, and symptomatic fever, arising from the severity of the operation, are removed. In many instances it will be necessary to use alteratives; sometimes of the mercurial, and sometimes of the antimonial kind, given internally or joined with antiseptics, as the bark in substance or decoction, or infusions with common or simple lime-water, the aqua calcis magra or minor composita of the London Dispensatory, or decoctions of equal parts of sassafras and sarsaparilla. Warner on the Eye, p. 18—26.

FISTULA *in perinæo* is usually the consequence of lithotomy, or making a puncture near the urethra, or from a scrofula of the prostrate gland, or from a wound or ulcer, the lips of which become callous, and form a *fistula*, through which the urine is preternaturally discharged. The circumstances attending different cases of this kind are so various, that only general rules can be laid down for a cure. Accordingly, the outward opening must be enlarged by cutting away the callous lips, or destroying them by caustic: in some cases it will be sufficient to introduce a bougie into the urethra for dilending it. Le Dran observes, that though there are several fistulous orifices, and several callosities in the perinæum, and when the water passes off through the natural passage in a small stream, the chief remedy will be the introduction of bougies; and that as this canal is enlarged, the external orifices are lessened and healed, and the callosities softened. See Le Dran's operations.

FISTULA *pulmonis*, in *Anatomy*, a term used by some writers for the *aspera arteria*.

FISTULA *sacra*, in *Anatomy*, is that part of the back-bone which is perforated.

FISTULÆ *urinariæ*, in *Anatomy*, the same with the urethra.

FISTULOUS, or FISTULOUS, is applied by the surgeons to wounds and ulcers which degenerate into fistulas.

FISTULAR is also applied to the leaves of plants which are round and hollow within; as the leaves of leeks, &c.

FISTULAR *flowers*, among *Herbalists*, are those made up of many small, long, hollow flowers, like pipes.

FIT, *in Medicine*, an accels or PAROXYSM.

Dr. Cheyne is of opinion, that *fits* of all kinds, whether epileptic, hysteric, or apoplectic, may be cured solely by a milk diet, of about two quarts of cow's milk a day, without any other food. Cheyne, Nat. Meth. of Curing, p. 365. See CONVULSIONS.

FITS *of easy reflection* and *easy transmission*. See LIGHT.

FITS *of the mother*. See HYSTERIC *affection*.

FITCHEE, or FICHEE, in *Heraldry*, is when the lower part of any cross is sharpened into a point fit to fix into the ground.

Thus, he bears azure, a cross-potent *fitchee*. *See Tab. Heraldry, fig.* 24.

The origin hereof M'Kenzie ascribes to the primitive Christians, who used to carry their crosses with them wherever they went; and when they stopped at any place in a journey, fixed them in the ground.

FITCHES, a name given by our farmers to a sort of pulse which they sow in their fields. Many suppose it the same with the tare, but erroneously; it is the vetch or chich-pea of authors. There are two principal kinds of this in use among us, the winter and the summer *fitch*. The one is sown before winter, and abides the extremity of it; the other is sown in spring. They are propagated in the same manner as peafe, and they make a very good and nourishing food for cattle, whether given in straw or threshed out. They are sometimes sown only to improve the land. In this case they are to be plowed in, just as they are beginning to blossom, and in this manner they finely enrich a tough stiff clay.

FITCHET, a name used in some places for the WEASEL; called also the *fichet* and the *foumart*. See POLECAT.

FITTING-*out*, in *Naval Language*, the act of providing a ship with a sufficient number of men, to navigate and arm her for attack or defence; as also of furnishing her with proper masts, sails, yards, ammunition, artillery, cordage, anchors, and other naval furniture, together with sufficient provisions for the ship's company. See CREW.

FITZ, a French term, literally denoting *son*; sometimes given by way of addition to the natural sons of the kings of England; as James *Fitz-Roy*, duke of Grafton, &c.

FIVE-*leaved Grass*, *Cinquefoil*, in *Heraldry*, is used by such as would introduce a blazon by herbs and flowers instead of metals and colours, to signify VERT, or *green*.

FIVES, among *Farriers*. See VIVES.

FIXATION, the act of fixing, or of rendering a thing firm and fixed.

FIXATION is applied in the general to any process that fixes and binds together what, of its own nature, is volatile; and enables it to sustain the fols of fire for some considerable time.

Geber defines *fixation* an operation whereby a volatile thing, i. e. a thing that cannot endure the fire, is rendered capable of enduring it. In the general, *fixation* is the changing of a volatile body into a fixed one.

FIXATION, among *Alchemists*, denotes a peculiar preparation of mercury, whereby it is to be put in a condition to bear the fire without evaporating, as the hammer without flying or separating.

The alchemists hold, that if they had the true secret of fixing mercury without the addition of any foreign less heavy and solid ingredient, they could make gold, or at least silver.

M. Homberg had a long process of many months to prepare an oil from the fecal matter of human excrements; which, he imagined, would have fixed mercury into silver; but it failed.

FIXED *Air*. See AIR.

FIXED *bodies*, in the general, are those which neither the fire nor any corrosive has such effect on, as to reduce or resolve them into their component elements; i. e. absolutely to destroy them.

Chauvin holds it not sufficient to denominate a body *fixed* that it can withstand the fire or any one agent, but it should withstand all. He contends, that *fixity* should not be restrained, as it usually is, to an exemption from evaporation, but from destruction, or resolution into primary elements: in this sense, gold, precious stones, and

phur, and even sulphur, and mercury itself, are properly *fixed bodies*; for mercury and sulphur retain their nature notwithstanding all their evaporation.

The chemists divide all natural bodies into *fixed* and volatile; i. e. such as bear the utmost force of the fire without dissipating or spending themselves in fume, and such as do not.

Of *fixed bodies*, the principal are platina, gold, silver, precious stones, particularly the diamond; salts, &c.

Of all metals, gold and silver alone are fixed; i. e. on remaining a long time exposed to the most intense flame, they alone, lose nothing of their weight.

Whence this property should arise is difficult to say. If the reader is not concerned with the causes enumerated under FIXITY, he may add the following one from Boerhaave, viz. the homogeneity and equality of the parts. The parts, e. gr. of gold being all homogeneous, and equal, will equally sustain each other, and leave equal pores between them; through which pores, when fused, the fire finding an easy, equal passage, goes off, without carrying any thing of the metal with it; or rather the particles of gold being of all others the most solid and heavy (as appears from the weight of that metal) and of all others the most strongly united or bound together (as appears from the immense ductility of that metal), the force of the fire is not sufficient to overcome so powerful a resistance: the solidity of the particles, and their freedom from air, prevents their being earched, or set farther apart, which might lessen their specific gravity, and diminish their *vis cohæsionis*; to that what has the chief effect in the raising of fumes and vapours, viz. the rarefaction or expansion of the body being here precluded, the metal maintains its natural weight and tendency to the centre.

Mr. Boyle, the prince of Mirandola, M. Homberg, and others, have made numerous experiments on gold, silver, &c. to see how far their fixity extended; in these, pure gold, kept in an intense heat for two months, lost nothing sensible of its weight: SILVER, under the like circumstances, and in the like time, lost one-twelfth part of its weight: but Mr. Boyle attributes this to the metal's not being fine and pure.

Indeed, by the great burning-glasses of Messr. Tschirnhausen and Villette, the most *fixed bodies*, as gold itself, are rendered volatile, and lose of their weight; so that there is no body in all nature absolutely *fixed*.

FIXED *line of defence*, a line drawn along the face of the bastion, and terminating in the curtain. See DEFENCE.

FIXED *nitre*, a preparation of saltpetre, made by fusing it in a crucible, and then inflaming it, with throwing in a few coals; and thus again and again, till no more flame or detonation arise; then, letting it cool, they pulverise and dissolve it in water, and afterwards evaporate it into a fine white salt, which serves to draw the tinctures out of vegetables. This salt, *per deliquium*, yields what they call the *liquor of fixed nitre*.

FIXED *salts* are those extracted or gained from bodies by calcination and lotion. See SALTS.

They are called *fixed*, because the fire was not able to sublime or raise them; as those carried off in the course of calcination by the vehemence of fire are called *volatile*.

The ashes of all plants yield *fixed salts*. See LIXIVIUM.

FIXED *signs of the Zodiac*, according to some, are the *signs* TAURUS, LEO, SCORPIO, and AQUARIUS.

They are so called because the sun passes them respectively in the middle of each quarter, when that season is more settled and *fixed* than under the sign which begins and ends it.

FIXED *stars* are such as constantly retain the same position and distance with respect to each other.

By which they are contra-distinguished from erratic or wandering stars, which are continually shifting their situation and distance.

The *fixed stars* are what we properly and absolutely call STARS; the rest have their peculiar denomination of PLANET and COMET.

FIXEN, among *Sportsmen*. See VIXEN.

FIXES is a name given by the workmen in gold and silver to a solution of silver, from its use in carrying down and *fixing* the heterogeneous acids mingled with aqua fortis.

FIXING *Sulphur*. See SULPHUR.

FIXITY, or FIXEDNESS, in *Philosophy*, the quality of a body which denominates and renders it fixed; or a property which enables it to endure the fire and other violent agents.

According to Chomel, *fixity* consists in this; that the component principles of the body are so closely united or cohere so strongly, and are mixed in such proportion that they cannot easily be divided either by fire or any other corrosive menstruum, or their integral parts separated and carried off in vapour; for a body may be said to be fixed in two respects.

First, When, on being exposed to the fire, or a corrosive menstruum, its particles are indeed separated, and the body rendered fluid, but without being resolved into its first elements. The second, when the body sustains the active force of the fire or menstruums whilst its integral parts are not carried off in fumes. Each kind of *fixity* is the result of a strong or intimate cohesion between the particles mixed.

FIXITY, or FIXEDNESS, in *Chymistry*, is, in a peculiar manner, used for the affection opposite to VOLATILITY; i. e. the property whereby bodies bear the action of the fire, without being dissipated in fumes.

The principle causes of *fixity*, or the qualifications that contribute most to the rendering a body fixed, according to Mr. Boyle, are, 1. That its corpuscles be single of a certain proportionable bulk, too big and unwieldy to be carried up by heat, or buoyed up in the air. 2. That they have also a proper degree of weight or solidity. 3. That their figure be such as unfits them for evaporation or flying off; some being branched, others hooked, &c. so that being entangled with one another, they cannot easily be extricated, loosened, and separated. To these may be added a fourth circumstance, viz. the nearness of the particles, and their being contiguous in a great many points, or large extent of surface, which produces a stronger force of attraction and cohesion.

FLACCIDITY, in *Medicine*, &c. a disorder of the fibres or solid parts of the body, opposite to *rigidity*.

The too great *flaccidity* of the parts is cured by cardiacs, exercise, friction, a dry warm air, proper food, &c.

FLAG, a general name, including colours, standards, ancients, banners, ensigns, &c. which authors frequently confound with each other.

The fashion of bearing the *flags* pointed or triangular, which now obtains, Roderic. Toletanus assures us, came from the Mahometan Arabs or Saracens, upon their seizing of Spain, before which time all the ensigns of war were square, stretched, or extended, or cross pieces of wood, like church-banners; on which account they were called in Latin *vexilla*, q. d. *velilla, a veli diminutione*, as is remarked by Isidore.

The pirates of Algiers, and those throughout the coast of Barbary, are the only people who bear an hexagonal *flag*. It is gules, charged with a moresk head, cuised with its turban, &c. though this be expressly contrary to their law, which prohibits the making any image or representation of a man, founded on an opinion, that they who make them shall be obliged at the day of judgment to find souls for them, and that in defect hereof they shall be damned. But this portrait which they carry is that of Hali, Mahomet's son-in-law, to whose party the Africans all retain, who ordered that his effigy should be expressed on their *flags* and flandards, believing himself so formidable to the Christians, that the bare sight of his image would carry undoubted victory over them. Leunclavius.

FLAGS, in the *Military Art*, are small banners of distinction stuck in the baggage-wagons of the army, to distinguish the baggage of one brigade from another, and of one battalion from another, that they may be marshalled by the waggon-master-general according to the rank of their brigades, to avoid the confusion that otherwise might arise.

FLAG is more particularly used in *Sea-language*, for the colours, ancients, flandards, &c. borne on the top of the masts of vessels, to notify the quality of the person who commands the ship, of what nation it is, and whether it be equipped for war or trade.

In the British navy *flags* are either red, white, or blue, and are displayed from the top of the main-mast, foremast, or mizzen-mast, according to the rank of the admiral. The first flag in Great Britain is the Royal flandard, which is only to be hoisted when the king or queen are aboard the vessel. The second is that of the anchor of hope, which characterises the lord high admiral, or lords commissioners of the admiralty; and the third is the union *flag*, in which the crosses of St. George and St. Andrew are blended: this last is appropriated to the admiral of the fleet, who is the first military officer under the lord high admiral.

The admiral or commander in chief carries his *flag* on the main-mast; the vice admiral carries his on the fore-mast; and the rear-admiral his on the mizzen-mast.

The next *flag* after the union is that of the white squadron, at the main-mast; and the last which characterises an admiral is the blue, at the same mast-head. For a vice-admiral, the first *flag* is the red; the second, the white; the third, the blue, at the *flag*-staff on the fore-mast. The same order proceeds with regard to the rear-admirals, whose flags are hoisted on the top of the mizzen mast; so that the lowest flag in our navy is the blue on the mizzen-mast. When a council of war is held at sea, if it be on board the admiral, they hang a *flag* on the

the main-shrouds; if in the vice-admiral, in the fore-shrouds; and if in the rear-admiral, in the mizzen-shrouds. The *flags* borne on the mizzen are particularly called *pallants*. See MAST, &c.

The *flag* of the French nation is blue, charged with a white cross, and the arms of France.

Beside the national *flag*, merchant-ships frequently bear lesser *flags* on the mizzen mast, with the arms of the city where the master ordinarily resides, and on the fore-mast with the arms of the place where the person who freights them lives. See *Table of Flags*.

FLAG, *to hoist out the*, is to put out or hang abroad the *flag*.

FLAG, *to hang out the white*, is to ask quarter; or it shews when a vessel is arrived on a coast that it has no hostile intention, but comes to trade, or the like. The red *flag* is a sign of defiance, and battle.

FLAG, *to lower*, or *strike the*, is to pull it down or take it in, out of respect or submission, when a weaker party meets a more powerful one.

By an ordinance of Philip II. king of Spain, 1565, the captains are peremptorily commanded to perish rather than lower their royal *flag* when once hung out.

The way of leading vanquished ships in triumph is, to tie the *flag* to the shrouds, or the gallery in the hind-part of the ship, and let them hang down towards the water, and so tow the vessels by the stern. It was thus the Romans used those of Carthage, as Livy relates.

FLAG-*officers*, those who command the several squadrons of a fleet; as admirals, vice-admirals, and rear-admirals.

The *flag-officers* in our sea-pay, are the admiral, vice-admiral, and rear-admiral, of the white, red, and blue.

FLAG-*ship*, a ship commanded by a general or *flag*-officer, who has a right to carry a *flag*, in contra-distinction to the secondary vessels under the command thereof.

FLAG-*staves*, are the staves set on the heads of the top-gallant masts, serving to let fly and unfurl the *flag*.

FLAG, in *Natural History*, a genus of harsh and rough STONES, composed of a visible grit of a laminated structure, and splitting only horizontally or into plates. M. da Costa distributes them into alkaline *flags*, or laminated sand-stone, and such as are not acted upon by acids. Of the former kind are the ashen-coloured *flags*, the laminæ of which are numerous and very visible, and so thin as sometimes not to exceed the thickness of brown paper; so that in a piece of half an inch thick seven or eight perfect laminæ are often discernible: this, by being burnt, becomes extremely friable, and of a white colour: it is dug in several parts of the kingdom, and is frequently used to cover houses instead of tiles, though it is very unfit for the purpose, as it bears the weather badly, and crumbles after frosts: and the ashen brown-coloured *flags*, of a more compact texture, and heavier than the former, though composed like that of an irregular grit cemented by a coarse spar; this becomes friable by being burnt, but suffers no change of colour: there are quarries of it at Burford in Oxfordshire, where it is used to slate houses, for pavements, &c. Neither this nor the former will strike fire with steel.

The *flag* or *slate stone* common in Northumberland and some of the neighbouring counties is called by some *Carlisle* and *white flag*. It is a white fossile stone, easily splitting into thin plates, and is full of small spangles of a fine glittering talc. It is also common in Yorkshire and the neighbouring places; it varies a little in colour, being sometimes grey, sometimes brownish, and sometimes merely whitish. Its strata are very thick, but they easily separate into laminæ of about half an inch thick, and the workmen seldom attempt to split it any thinner; the upper strata, however, grow gradually thinner, and the bottom ones are so thick as not to be used for slates. These they raise, however, and use for tanners fats, the pavements of floors, and cisterns for water.

The Stunsfield slate is of a pale brownish colour, very hard and heavy, and its flats or the surfaces of the laminæ are always thick set with small bivalves, but few or none are imbedded in its fossil substance: it burns to a browner colour. This *flag-stone* is dug out of the quarries at Stunsfield in Oxfordshire, in the winter season, and laid in large masses in the open air till summer, and thus rendered fissile: the plates into which it is split are the common slating-stone in those parts: the upper stratum of the quarries is a soft gritty laminated stone, violently fermenting in aqua fortis, used as a sort of whet-stone; neither of these two last species will readily strike fire with steel. The pale, whitish, brown-coloured *flag* is of a compact and uniform structure; and the grit that forms it is so intimately blended with marine bodies, and saturated and cemented to such a degree with fine sparry matter, that the gritty texture of the stone is hardly visible. No part of it is changed by burning, except the shells that are lodged in it. It will not strike fire with steel. There are several strata of this stone in the neighbourhood of Bath, where it is used as slate for covering houses. The deep, dusky, lead-coloured *flag* is extremely hard and heavy, of a compact texture, composed of a small grit, which is cemented together by an earthy, sparry, and cryftalline substance: its flat surfaces are bespangled with great numbers of fine talcy particles; the plates are generally very regular and thin, not exceeding the tenth part of an inch in thickness, and cohere so firmly together as not to be easily separated. This stone readily strikes fire with steel, and, being burnt, acquires a reddish brown colour. It is dug in several parts of Italy, and much used in building. The first, second, and fifth species above mentioned are destitute of any brightness; the fourth has, interiorly, some small degree of lustre; but the third and last are very bright and glittering. Of *flags* which are not acted upon by acids, there are the following species: the *flag* of fullied white colour, which is composed of a large irregular cryftalline grit cohering loosely together, and cemented with a terrene cryftalline substance: the flat surfaces of the plates are covered with great quantities of small spangles of fine talc, which render them very sparkling and dazzling. This stone is very heavy, and pretty hard, and the laminæ are generally very regular and thin; a *flag* of two inches thick, having often fourteen or fifteen plates: it will not strike fire with steel; when burnt, it acquires a clearer white colour, with a slight reddish hue, and becomes very friable. It is dug in several parts of the kingdom, and used much as slate, for pavements, &c.

The bright and glittering *flag* is the hardest stone of this genus, and generally variegated with white and purple, and often the plates have one of these colours only. It is of a compact texture, and thickly spangled with small laminæ: strikes fire with steel, and acquires a paler colour by being burnt. It is much used in Italy, where it is dug for pavements. The brown coloured *flag* is composed, like the others, of an irregular grit, cemented by a cryftalline substance; it is moderately hard and heavy; its flat surfaces are covered with small spangles of a silvery talc, and its laminæ are thin and numerous: it burns to a pale reddish colour. It is dug in England, and very commonly in Sweden, but not applied to any particular use. Da Costa's Fossils, p. 144—148. Hill's Hist. of Fossils, p. 433. &c.

FLAG or FLAG-*flower*, in *Botany*. See IRIS.

FLAG is also used for a kind of rush called sedge, as well as for the upper part of turf pared off to burn.

FLAG, *cyrus*, in *Botany*, *gladiolus*, a genus of the *triandria monogynia* class. Its characters are these: the flowers are included in sheaths: the petal of the flower is cut into six parts, and form a short incurved tube with their base; they have three awl-shaped stamina, which are inserted into every other petal. The germen is situated below the flower, which afterward becomes an oblong, swelling, three-cornered capsule with three cells, filled with roundish seeds. Miller reckons six species.

The root of the common *cyrus-flag* or *gladiole* is accounted discutient, and good in malignant and pestilential cases.

FLAG, *sweet-scented*. See ACORUS.

FLAGS, in *Falconry*, are the feathers in a hawk's wing near the principal ones.

FLAG-*worm*, a worm so called from being found in sedgy places.

FLAGELLANTES, a sect of wild fanatics who chastised and disciplined themselves with whips in public.

The sect of the *Flagellantes* had its rise in Italy in the year 1260; its author was one Rainier, a hermit; and it was propagated from hence through almost all the countries of Europe. It was in all probability no more than the effect of an indiscreet zeal. A great number of persons of all ages and sexes made processions, walking two by two with their shoulders bare, which they whipped till the blood ran down, in order to obtain mercy from God, and appease his indignation against the wicked-ness of the age. They were then called the *devout*; and having established a superior, he was called the *general of the devotion*. Though the primitive *Flagellantes* were exemplary in point of morals, yet they were joined by a turbulent rabble, who were infected with the most ridiculous and impious opinions; in that the emperors and pontiffs thought proper to put an end to this religious phrenzy, by declaring all devout whipping contrary to the Divine law, and prejudicial to the soul's eternal interest.

However, this sect revived in Germany towards the middle of the next century, and rambling through many provinces, occasioned great disturbances. They held, among other things, that flagellation was of equal virtue with baptism, and the other sacraments; that the forgiveness of all sins was to be obtained by it from God, without the merits of Jesus Christ; that the old law of Christ was soon to be abolished, and that a new law enjoining the baptism of blood to be administered by whip-

ping was to be substituted in its place: upon which Clement VII. by an injudicious as well as unrighteous policy, thundered out anathemas against the *Flagellants*, who were burnt by the inquisition in several places; but they were not easily extirpated. They appeared again in Thuringia and Lower Saxony in the fifteenth century, and rejected not only the sacraments, but every branch of external worship, and placed their only hopes of salvation in faith and flagellation, to which they added other strange doctrines concerning evil spirits. Their leader Conrad Schmidt and many others were committed to the flames by German inquisitors, in and after the year 1414. Mosheim's Eccl. Hist. vol. iii. p. 94, &c. 206 and 277, &c. Eng. 8vo. edit. 1758.

FLAGELLARIA, in *Botany*, a genus of the *hexandria trigynia* class, without any corolla; the calyx is divided into six segments, and the fruit is a berry containing a single seed.

FLAGELLATION, *schesipsus*, a voluntary discipline or penance, frequently practised by the ancient penitents. See DISCIPLINE.

The parliament at Paris prohibited all public *flagellations* by an arret of 1601. See FLAGELLANTES.

FLAGELLATION is a term more peculiarly appropriated to the sufferings of Jesus Christ, when whipped and scourged by the Jews; from the Latin, *flagellum*, *a scourge* or *whip*.

We say, a painting of the *flagellation*; or, simply, a *flagellation*, to denote a picture or print representing this torment inflicted on the Saviour of the world.

In this sense we say the *flagellation* of such a painter, &c.

FLAGEOLET, or FLAJOLET, a kind of little flute; or a musical instrument of the flute kind, used chiefly by shepherds and country people.

It is usually made of box, or some other hard wood, sometimes of ivory. It has six holes or stops before that at bottom, the mouth-piece, and that behind the neck.

The ambit of the *flageolet*, according to the scale exhibited by Mersennus, is two octaves from *g sol re ut* upwards.

FLAIL. See THRASHING.

FLAIR, in *Sea-language*. The seamen say that the work doth *flair-over*, when a flap being hooked in near the water, so that the work hangs over a little too much, and thus is let out broader aloft than the due proportion will allow.

FLAIRS, in *Ichthyology*, a name given by some to the SCATE, a species of the RAIA.

The ancient Greeks called this RAIA OXE, when they spoke of the males, and when of the female, PAYIS.

FLAIRING, in *Sea-language*. See FLAIR.

FLAKE, in the *Cod-fishery*, a sort of scaffold or platform, made of hurdles, and supported by stanchions, and used for drying cod-fish in Newfoundland. These *flakes* are usually placed over the shores of fishing-harbours.

FLAKE, in *Gardening*, a name given by the florists to a sort of carnations, which are of two colours only, and have very large stripes, all of them going quite through the leaves.

FLAKE, *white*, in *Painting*, is lead corroded by means of the pressing of grapes, or a cerule prepared by the acid of grapes. It is brought here from Italy, and for purposes, both with regard to the purity of its whiteness and the certainty of its standing, all the cerule or white lead made with us in common. It is used in oil and varnish painting for all purposes, where a very clean white is required. The white *flake* should be procured in lumps as it is brought over, and levigated by those who use it, because that which the colourmen sell in a prepared state is levigated and mixed up with starch, and often with white lead, and worse sophistications.

FLAMBEAU, or FLAMBOY, a luminary made of several thick wicks, covered over with wax, serving to burn at nights in the streets; as also at funeral processions, illuminations, &c.

Flambeaux differ from links, torches, and rapers. See TORCH.

They are made square, sometimes of white wax, and sometimes of yellow; they usually consist of four wicks or branches near an inch thick, and about three feet long, made of a sort of coarse hempen yarn, half twisted. They are made with the ladle, much as torches or rapers are, viz. by first pouring the melted wax on the top of the several suspended wicks, and letting it run down to the bottom; this they repeat twice. After each wick has thus got its proper cover of wax, they lay them to dry; turn out them on a table, and so join four of them together by means of a red hot iron.

When joined, they pour on more wax till the *flambeau* is brought to the size required, which is usually from a pound and a half to three pounds.

The last thing is to finish their form or outside, which they do with a kind of polishing instrument of wood by running it along all the angles formed by the union of the branches.

The *flambeaux* of the ancients were different from ours. They were made of woods, dried in furnaces, or otherwise. They used divers kinds of woods for this purpose; the wood most usual was pine. Pliny says, that in his time they frequently also burnt oak, elm, and laurel. In the seventh book of the Æneid, mention is made of a *flambeau* of pine; and Servius, on that passage, remarks, that they also made them of the cornel-tree.

FLAMBO, in *Natural History*, a name given by some to a long anguilliform fish, a species of the TÆNIA, called CATAGARO.

FLAME, the brightest and subtilest part of the fuel, ascending above it in a pyramidal or conical figure.

Flame seems to be the smoke, i. e. the fumes or volatile part of the fuel, greatly rarefied, and at last kindled or heated red-hot. By the great rarefaction, the matter becomes so light as to be raised with great velocity in the air; and by the pressure of the incumbent atmospherical fluid, it is kept for some time together, the air forming a sort of such a sphere round it, that prevents its immediate diffusion and dissipation, and by its contrariety and fixation sustains and feeds the fire of the *flame*: the aqueous and earthy parts of the fume being naturally incapable of being ignited, are only rarefied, and so impelled upwards in a dusky cloud without flaming.

Flame is defined by sir Isaac Newton in his little piece De Aëre, to be *fumus candens, red-hot smoke*. But Dr. Priestley has properly observed, that the smoke of common fuel consists of two very different things: that which rises first is mere water, loaded with some of the grosser parts of the fuel, and is hardly more capable of becoming red-hot than water itself: but the other kind of smoke which alone is capable of ignition, is properly *inflammable* AIR, which is also loaded with other heterogeneous matter, so as to appear like a very dense smoke. A lighted candle soon shews them to be essentially different; for one of them instantly takes fire, whereas the other extinguishes a candle. Priestley on Air, vol. I. p. 207.

Flame may be considered as vapour composed of inflammable parts, and kindled by contact with an ignited body; by which means, together with the access of air or nitrous acids, it may be made to undergo those effects which are produced upon all bodies during their combustion, viz. the fecond poffion of its parts, the diffipation of its phlogiston, and the emiffion of light and heat. Moreover, it is not merely the vapour of an inflammable body, but the body itself, that may, by contact with an ignited body, or by any other mode of exciting heat, as friction, &c. together with access of air or nitrous acid, emit a *flame*, which conffts of particles flying off from that body in the act of combuffion. Thus, by applying a hot iron to fulphur, we may fee a *flame* immediately produced upon the furface of the fulphur; and bodies thus kindled can only *flame* at their furfaces, becaufe there only they are contiguous to the air; whereas, when nitre is intimately mixed with the inflammable fubftance, as in gunpowder, the whole fubftance is inftantly inflamed, becaufe the nitrous acid has, like air, the property of maintaining combuffion. See *Nitrous* AIR. Hence we may alfo conceive why the external furface of a *flame*, by being contiguous to air, is much hotter than its internal parts, which may be eafily evinced by applying any fubftance, alterable by heat, alternately to the exterior and interior parts of the *flame* of a candle; and when a vapour of a foot or eighteen inches diameter is kindled, and the combuffion maintained only by the air contiguous to it, the *flame* will then be only an inch or two thick, while the vapour near the centre, furrounded by the *flame*, is not inflamed. See the remarks of the ingenious tranflator of the Chemical Dict. Art. *Flame*. Sir Isaac Newton, to whofe reafoning we return after this digreffion, argues, Is not *flame* a vapour, fume, or exhalation heated red-hot; that is, fo hot as to fhine? For bodies do not *flame* without emitting a copious fume; and this fume burns in the *flame*. The ignis fatuus is a vapour fhining without heat; and is there not the fame difference between this vapour and *flame* as between rotten wood fhining without heat, and burning coals of fire? in diftilling hot fpirits, if the head of the ftill be taken off, the vapour which afcends will take fire at the *flame* of a candle, and turn into *flame*. Some bodies, heated by motion or fermentation, if the heat grow intenfe, fume copioufly; and if the heat be great enough, the fumes will fhine, and become *flame*. Metals in fufion do not *flame*, for want of a copious fume. All *flaming* bodies, as oil, tallow, wax, wood, foffil coal, pitch, fulphur, &c. by burning, waffe in fmoke, which at firft is lucid; but at a little diftance from the body ceafes to be lu. id, and only continues hot. When the *flame* is put out, the fmoke is thick, and frequently

smells strongly: but in the *flame* it loses its smell; and, according to the nature of the fuel, the *flame* is of divers colours. That of sulphur, e. gr. is blue; that of copper opened with sublimate, green: that of tallow, yellow; of camphor, white, &c.

From this difference of the colours of the *flames* proceeds the difference of the colours of bodies as viewed by day-light, candle-light, or any one of these *flames*; and for making curious experiments of this kind, oil may be impregnated with copper, &c.

We find that when gun-powder takes fire, it goes off in a *flaming* smoke. The manner we conceive to be this: the charcoal and sulphur easily take fire, and set fire to the nitre; by which the spirit of the nitre being rarefied into vapour, rushes out like the vapour of water out of an eolipile. Then the acid spirit of the sulphur entering violently into the fixed body of the nitre, sets loose the spirit of the nitre, and excites a greater fermentation, whereby the heat is increased, and the fixed body of the nitre rarefied into fume, and thus is a vehement explosion effected. The *flame* of gun powder arises from a subtle action, whereby the mixt being quickly and vehemently heated, is rarefied and converted into fume and vapour; which vapour, by the violence of the action becoming so hot as to shine, appears in the form of *flame*. Newt. Optics, p. 318. See AIR, FIRE, HEAT, and PHLOGISTON.

It is a remarkable phenomenon of the *flame* of a candle, torch, or the like, that in the dark it appears bigger at a distance than near at hand. The reason is, that at a distance, e. gr. of six feet, the eye can readily distinguish between the *flame* and the contiguous air illuminated by it, and sees precisely where the *flame* terminates; but at the distance, e. gr. of thirty feet, though the angle subtended by the *flame* be much smaller than before, yet the eye, not being able to distinguish the precise bound of the *flame*, takes part of the sphere of air illuminated by it for the *flame* itself.

We have several instances of actual *flame* being produced by the mixture of two cold liquors. Dr Slare gives us a list of the oils which burst into *flame* upon mixing them with compound spirit of nitre; such are those of caraways, cloves, sassafras, guaiacum, box, camphor, pepper, hartshorn, blood, &c. Philosoph. Trans. N° 213.

It is evident to every curious observer, that *flame* dwells and plays only about the surface of fuel, having nothing to do with its interior parts. If a lamp-glass be filled with spirit of wine, another with oil of turpentine, and others with other liquors, and each set on fire, it will be easily distinguishable through the sides of the glass, that they all burn and *flame* only on their surface, the *flame* continually sinking lower and lower in the glasses as the liquors consume. The same observation holds good in solid as well as liquid fuel, and appears to be universal; and hence we are directed to the choice of proper fuel on the different occasions we want it for. Shaw's Lect. p. 33.

It is observed by Neumann, that the face viewed by the *flame* of nine looks like that of a dead corpse; the *flame* of phosphorus, and of spirit of wine impregnated with sea-salt, exhibit the same phenomenon. For the effect of joining the *flame* of two candles, see CANDLES. For an account of the generation and extinction of *flame*, according to the theory of Dr. Crawford, see HEAT of *inflammable, &c. bodies*.

FLAME *from cold liquors*. See FIRE.

FLAME-*heat*, the same with white-heat. See IRON.

FLAME, *vital*, FLAMMA, or FLAMMULA *vitalis*, a fine, warm, igneous substance, supposed by many both of the ancients and moderns to reside in the hearts of animals, as necessary to life, or rather as that which constitutes life itself.

To the preservation of this *flame*, they suppose air as necessary as it is to the preservation of common *flame*; and hence they ascribe the necessity of respiration to animal life.

Mr. Boyle, by experiments in an exhausted receiver, found, that the *vital flame of animals*, if life may be so called, survives or outlasts the *flame* of spirit of wine, or of a wax or tallow candle, &c. Some animals would remain alive and well in vacuo for three or four minutes, whereas no common *flame* would last there one minute. The light of the glow-worm, he found, would presently be destroyed by exhausting the air, and retrieved again upon its re-admission. Dr Quincy could find nothing more in the notion of vital *flame* than the natural warmth, which is the effect of a circulating blood, and which is always as its velocity. See *Animal* HEAT.

FLAMEN, among the ancient Romans, was a priest or minister of sacrifice.

There were at many kinds *of flamens* at Rome as there were gods who had priests and sacrifices offered them. Romulus and Numa, at first, only instituted three; one for Jupiter, called *flamen Dialis*; another for Mars, called *flamen Martialis*; and a third for Romulus or Quirinus, called *flamen Quirinalis*. Plutarch and Dionysius Halicarnassæus maintain, that Numa created only the last in honour of Romulus; but Livy affures us, that Romulus had inftituted only the firft, and that the two others were added by Numa; and Varro fpeaks in the plural number of the *flamines* inftituted by Numa. In after-times twelve more were added, which made the number of *flamens* fifteen.

The three firft were taken from among the patricians, and were held of a rank and diftinction fuperior to the reft. They were called *greater flamens*, *flamines majores*, in contradiftinction to the other twelve, who were chofen from among the plebeians, and were therefore called *leffer flamens*, *flamines minores*. The *flamen Dialis*, or of Jupiter, was the firft inftituted, and held in the greateft renown. He bore a peculiar ornament on his head, called *apex*, which was made of the fkin of a white victim facrificed to Jupiter.

One of thefe priefts revived an ancient pretenfion to a feat in the fenate in right of his office, which, by the indulgence of his predeceffors, had not been claimed or enjoyed for many generations. The orator refifted his claim, nor would fuffer him to fit in that aflembly; but upon his appeal to the inftinct of the people; that is, to the gods, his right was confirmed, and he was allowed to take his place as a fenator. Liv. xxvii. 8. Middlet. of Rom. Sen. p. 49.

The cap worn by the reft was called *flammeum operis*. It was made of a theep's fkin, with the wool on; to which was fattened a little branch of an olive-tree. That of the *flamen* of Jupiter ended in a point called *tutulus*. It was tied under the chin with ftrings: but in the fummer-time it was only a woollen thread tied round the head, it being prohibited them ever to appear quite bare-headed. And hence, according to Feftus, came their denomination of *flamen*, viz. from *filamen* or *filum*, thread.

Though the *flamens* bore one common appellation, yet did they not conftitute any company or college. Each god had his feveral facrifices, feafts, and ceremonies a-part; nor had one *flamen* any relation to another, only they were all fubordinate to the pontifex maximus. Aulus Gellius affures us, that they were created by the people in the comitia curiata; but the pontifex maximus afterwards confecrated them. Their prieftfhood, called *flaminatus*, was perpetual, though on fome occafions they might be depofed.

The names of the feveral *flamens* are as follow: the three great *flamens*, as already obferved, were the *flamen Dialis*, *flamen Martialis*, and *flamen Quirinalis*: the twelve leffer were the *flamen Carmentalis*, or prieft of the goddefs Carmenta, mentioned by Cicero in his Brutus; *flamen Palatis*, or prieft of the goddefs Palatua, a name whofe origin, Varro obferves, is not known; *flamen Pomonalis*, or of the goddefs Flora; *flamen Portunalis*, whofe etymology is not known; *flamen Lucinalis*; *flamen Lucinalis*; *flamen Palatualis*, whom fome moderns will have to be the prieft of the goddefs that prefided over the palatium, though Varro owns himfelf at a lofs for it original; *flamen Pomonalis*, or of Pomona, goddefs of fruits; *flamen Virbialis*, or of the god Virbius, whom fome take for the fame with Hippolytus; *flamen Volcanalis*, or of Vulcan; and *flamen Volturnalis*, or of the god Volturnus. Some authors alfo fpeak of the *flamen Hadrianalis*, prieft of Hadrian: *flamen Julii Cæsaris*, of Julius Cæfar; and *flamen Auguftalis*: and Commodus likewife had a *flamen* created under the title of *flamen Herculaneus Commodianus*.

They had alfo their *flaminæ* or *flaminica*, who were wives of the *flamens*, or the prieftefles of the deities. In an ancient marble, quoted by Gruter, p. cccxix. n. 9. the word *flaminica* is ufed for prieftefs; and in the fame author, p. ccxvii. n. 3. the prieftefs of the goddefs Feronia is called FLAM. FERON. that is *flamina*, or *flaminica Feroniæ*.

The *flaminica* bore the fame ornament on her head with the *flamen*. She had alfo the fame furname of office with her husband, as *flaminica Dialis*, *Martialis*, &c.

FLAMETTE, in *Ichthyology*, a name given by the French writers to a fpecies of chama or fhell-fifh of the bivalve kind, with its fhell always more or lefs open: this fpecies is as hot as pepper to the tafte.

FLAMINGO, in *Ornithology*, the name of a very beautiful and very remarkable bird; it has long legs, and a long neck; yet has webbed feet, and is remarkable for the fine bright red of its wings.

Its beak is broad and of a very fingular figure; the upper chap being bent, depreffed, and dentated; the lower, much thicker and ftrong. It is black at the end, and in the other part of a dufky blue. Its neck and body are white; the long flight feathers of its wings black;

but the shorter feathers, which make the covering of the wings, are of a very elegant and bright red, whence the bird has its name. It lives about waters, and feeds on fish: it is common in many parts of America, and is seen at times in many parts of Europe: it is well known to the ancients, and its tongue was accounted a very great delicacy among the like eaters of old times. See *Tab.* II. *of Birds*, N° 10.

One thing very remarkable about it is, that its beak is so long and crooked, that the whole head must be immersed before the water can get into it. See a learned and elaborate history of this bird in the Phil. Trans. Abr. vol. v. p. 61, &c.

FLAMMA *Jovis*, a name given by many writers to a plant of the *chamæce* or VIRGIN'S *bower* kind called by the Greek writers EUHODUS.

FLAMMULA, or FLAMMEL, under the *Eastern Empire*, was a kind of flag terminating in a point somewhat like a *flame*, bearing as a mark or badge to distinguish the soldiers of the several companies, battalions, regiments, &c. In Greek it was called *gonatis*: it was sometimes placed on the calques, sometimes on the cuirass, and sometimes at the end or tip of the pike, &c.

The emperor Maurice ordered, that the *flammula* of each division should be of a particular colour, to distinguish them from the other battalions or brigades.

They used to lay aside the *flammula* before an engagement, left it should prove an incumbrance. The cavalry had also *flammulæ* on their horses, to distinguish the troops they belonged to.

FLAMMULA, in *Botany*, a name given by some authors to a particular species of the crowfoot, commonly called the ranunculus flammeus.

FLAMMULÆ *aurei*, in *Natural History*, a name given by Dr. Woodward, and others, to those small pieces of gold found among the sands of rivers in some places. They are sometimes found in roundish pieces, but more usually in their shining flakes, whence the name *flammulæ* seems to have been given them, as being very bright and glossy.

This sort of gold is pure and malleable, and loses scarce any part of its weight in fusion.

The gold dust, as it is called, which is brought from Guinea is much of this kind; its particles are usually very small, though sometimes lumps of the size of a pea or bean are found, and sometimes masses of an irregular figure of three or four ounces weight; but these lose the name of *flammulæ* when they become so thick and solid, and so large, and are called by the merchants rock-gold. Woodw. Cat. Foss. vol. ii. p. 30. See GOLD.

FLANCH, FLASQUE, or FLASQUE, an ordinary in *Heraldry*, formed by an arched line, which begins at the corners of the chief, and ends at the base of the escutcheon.

He beareth ermin two *flanches* vert. See *Tab. Heraldry Sect.* 25. *Flanches* are always borne by pairs.

Leigh makes *flanque* and *flask* two distinct bearings, whereof the former is more bent than the latter; but Gibbon judiciously makes them but one, which he calls *flasque*.

FLANCONADE, in *Farriery*, is the action of dropping the point of your sword under your adversary's hilt, in seizing with force the feeble of his blade; which, binding without quitting it, form the parade in octave, and then throw in your thrust.

FLANEL, or FLANNEL, a kind of slight, loose, woollen stuff, not quilted, but very warm, composed of a woof and warp, and wove on a loom with two treddles, after the manner of BAYS.

It has been observed that new *flanel*, after some time wearing, acquires the property of shining in the dark, but before it is being washed. Philos. Trans. N° 483 § 7. See ELECTRICITY.

FLANK, or FLANK, in the *Manage*, is applied to the sides of a horse's buttocks, &c.

In a strict sense the *flanks* of a horse are the extremes of the belly, where the ribs are wanting, and are below the loins.

The *flanks* of a horse should be full, and at the top of each a feather. The distance between the last rib and haunch bone, which is properly the *flank*, should be short, which they term *well coupled*, such horses being most hardy, and fit to endure labour.

A horse is said to have no *flank* if the last of the short ribs be at a considerable distance from the haunch-bones; as also when the ribs are too much straightened in their compass.

FLANK, *in War*, is used by way of analogy for the side of a battalion, army, &c. in contradistinction to the *front* and *rear*.

To attack the enemy in flank, is to discover and fire upon them on one side. See FILE.

FLANK, in *Fortification*, is a line drawn from the extremity of the face toward the inside of the work. Such is the line BA, *Tab. Fortification, fig.* 1. and EF and LN, *fig.* 16.

Out flank is that part of a bastion which reaches from the curtain to the *face*, and defends the opposite face, the *flank*, and the curtain.

FLANK, *oblique or second*, is that part of the curtain, EI, intercepted between the greater line of defence, EC, and the lesser, IC; and from which they can see to scour the face of the opposite bastion.

FLANK, *low, covered, or retired*, is the platform of the casement which lies hid in the bastion; otherwise called the CRILLON.

FLANK *perdue* is that from whence a cannon playing, forth bullets directly in the face of the opposite bastion.

FLANK *reason, or reflect*, is the point from whence the line of defence begins, from the conjunction of which with the curtain, the face only raiseth the face of the next bastion, which happens when the face cannot be discovered but from the *flank* alone.

FLANKS, *simple*, are lines going from the angle of the shoulder to the curtain, whose chief office is for defence of the mount and place.

FLANKED, FLANQUE, is used by the French heralds to express our party per saltier; that is, when the field is divided into four parts, after the manner of an X.

Though Colombiere uses the term in another sense, which appears more natural, viz. for the taking of flanches, or rounding sections out of the sides of the escutcheons; the first from the angles of it, the latter in straight lines, forming an angle at the sole, without making any saltier.

FLANKED *angle*, in *Fortification*, is the angle formed by the two faces of the bastion, and which of course forms the point of the bastion.

FLANKED *line of defence*, in *Fortification*. See ANGLE and *Line of* DEFENCE.

FLANKED *tenaille*, is called also TENAILLE.

FLANKING, in the general, is the act of discovering and firing upon the side of a place, body, battalion, &c.

To flank a place, is to dispose a place or other work in such a manner as that there shall be no part of the place but what may be played on, both in front and rear.

Any fortification that has no defence but full right forwards is faulty, and to render it complete, one part ought to be made to *flank* the other. Hence the curtain is always the strongest part of any place, because it is *flanked* at each end.

Battalions also are said to be *flanked* by the wings of the cavalry. A house is sometimes said to be *flanked* with two pavilions, or two galleries, meaning it has a gallery, &c. on each side.

FLANKING *angle*. See ANGLE.

FLANKING *line of defence*. See *Line of* DEFENCE.

FLASK, in the *Artillery*. See POWDER *flask*.

FLASK, FLASQUE, a bearing more properly called *flanque* or FLANCH.

FLAT, in *Sea-language*, denotes a level ground, lying at a small depth under the surface of the sea, and is also called a shoal or shallow.

FLAT *bottom*, in *Fortification*. See BASTION.

FLAT-*bottomed boats* are such as are made to swim in shallow water, and to carry a great number of troops, artillery, ammunition, &c. They are constructed with a twelve-pounder, bow-chase, and an eighteen pounder, stern-chase; their keel is from ninety to one hundred feet, and from twelve to twenty-four feet beam: they have one mast, a large square main-sail, and a jib-sail, are rowed by eighteen or twenty oars, and can carry four hundred men each. The gun takes up one bow, and a bridge the other, over which the troops are to march. Those that carry horses have the fore-part of the boat made to open when the men are to march and ride over a bridge.

FLAT-*bottomed boat*, in *Fortification*. See MOAT.

FLAT-*crown*, in *Architecture*. See CORONA.

To FLAT-*in*, in *Seamanship*, is to draw in the aftmost lower corner or clue of a sail towards the middle of the ship, to give the sail a greater power of turning the vessel. Thus, if the mizzen or after-sails are *flatted-in*, this action is intended to carry the stern to leeward, and turn the head nearer to the direction of the wind; and if the head-sails are *flatted-in*, the intention is to make the ship fall off, when by accident, or design, she has come too near the wind as to make the sail shiver.

To FLAT-*in forward*, is to draw in the fore-sheet, jib-sheet, and foretopsail-sail-sheet toward the middle of the ship. This operation is seldom performed except in light breezes of wind, when the helm has not sufficient government of the ship.

FLATS, in *Music*, a kind of additional or half notes, contrived

trived together with sharps, to remedy the defects of musical instruments.

The natural scale of music being limited to fixed sounds, and adjusted to an instrument, the instrument will be found defective in several points; as particularly, in that we can only proceed from any note by one particular order of degrees; thus for this reason we cannot find any interval required from any note or letter upwards or downwards; and that a song may be so contrived, as that if it be begun by any particular note or letter, all the intervals or other notes shall be justly found on the instrument, or in the fixed series; yet were the song begun with any other note, we could not proceed.

To remove or supply this defect, musicians have recourse to a scale proceeding by twelve degrees; that is, thirteen notes, including the extremes, to an octave, which makes the instrument so perfect that there is but little to complain of. This, therefore, is the present system of the scale for instruments, viz. between the extremes of every tone of the natural scale is put a note, which divides it into two unequal parts, called *semitones*; and the whole may be called the *semitonic scale*, containing twelve semitones betwixt thirteen notes in the compass of the octave.

Now, to preserve the diatonic series distinct, these intermediate notes either take the name of the natural note next below with a character called a *sharp*; or they take the name of the natural note next above with a mark called *flat*. Thus D *flat* signifies a semitone below the D natural: and it is indifferent, in the main, whether the inserted note be accounted as a *flat* or a *sharp*.

The semitonic series or scale is very exactly represented by the keys of a spinnet; the foremost range or keys being the natural notes, and keys behind, the artificial notes, or the *flats* and *sharps*.

FLAT-*third*, in *Music*, the third minor. See INTERVAL.

FLATTER, or FLATTENER. } See COINING.
FLATTING, or FLATTENING. }

FLATTING-*mill*, among *Brick-makers*. See BRICK.

FLATTING-*mill*. See MILL and GOLD-*wire*.

FLATULENCY, a word used by medical writers to express a distempered state of the body, in which there is an uncommon and unnatural generation of flatules or hiatuous and elastic matter of the nature of air, arising from the humidity of the abdomen, and attended with several very bad symptoms.

Some authors mention flatules of the uterus and of the bladder; but these are very rare cases, though they do sometimes happen; and what is usually understood by the word *flatulency*, are such flatules in the stomach and bowels. These are either torpid or impetuous. The torpid *flatulencies* of the bowels give the patient very little uneasiness; people of phlegmatic habits are much subject to them, and generally very little regard them. But the impetuous kind very often occasion the utmost disorder, on the slightest accidental occasion irritating them; people of a sanguine and melancholic habit are most subject to them. *Flatuosities* differ also greatly in regard to their causes; for some are only occasioned by a simple languor or small loss of tone to the intestines, in which case the flatules are generally discharged upwards in eructations or downward, without trouble. Other *flatulencies* have their origin from a tough viscid matter, which destroys the intent of the peristaltic motion to this purpose; and in this case the patient is sometimes troubled with spastic constrictions of the intestines, sometimes with troublesome relaxations of them; and finally some *flatulencies* take their origin from a turbulent commotion of the blood about the vena porta, from the ramifications of this vessel having connections with the intestines.

Signs of flatulencies. The most obvious of these are the rumblings that are felt in the bowels, with noises in them; and in the place of these rumblings, there are sometimes plainly perceived fixed distensions of them in particular parts, with tensions and fractures of the abdomen. From the continuance of these symptoms arise pains which sometimes change place, and sometimes remain fixed, and seem to swell the intestines in such manner as to endanger bursting; and when commotions of the blood are the cause of these, there are usually pains felt attending them on the left side, and about the region of the heart, and the patient complains of the usual symptoms of hypochondriacal people.

An obstinate costiveness also usually attends this distemper, which always makes it more violent; and a shortness of the breath, attended with anxieties and difficulties of breathing, are usually the attendant symptoms on it, when violent. The more the *flatulency* has been owing to crudities in the primæ viæ, the more will the patient be affected with vertiginous complaints, and other *disorders* of the head; and when the cause is a commotion of blood about the vena porta, the pains are always very violent, and are often attended with bad consequences.

Persons subject to it. Flatulencies attack persons of all ages, sexes, and constitutions, but especially the phlegmatic, whose parts are of a weaker tone, and naturally more subject to expansion: after these, persons of a sanguine habit are most subject to them, and those of choleric and melancholic habits, though naturally less subject to them, yet often fall into them after illnesses.

People who are particularly sensible of the changes of the air from warmer to colder, are also more subject to them than those of a more robust and less delicate frame: hence women are more subject to them than men, and those especially in the times of the menses and lochia.

Causes of them. These are in general a relaxation of the peristaltic motion of the guts; but this not extending to the whole canal, but only to some one part, the transpiration of the hiatuous matter being chiefly into this flaccid part, which it distends in a manner that it could not do by any part that had its natural tone and motions. And the defect in one part is always attended with the excess of the peristaltic motion in another, in order to the driving off the cause; hence proceed alternate constrictions and relaxations, to which, in a great measure, the pain is owing; and in cases of the commotions of the blood about the vena porta, the same constrictions and relaxations always happen. The material causes of *flatulencies*, are those substances swallowed in food, which are of a mucous and tenacious consistence, and by their obstinately adhering to the bowels are capable of giving great trouble. Of this kind are the herbs in use in food, which are of a thick tough juice; or the leguminous tribe, as peas, beans, and the like; also dried sea-fish, and all animal fats, as that of sheep and calves, especially if the person drink immediately after eating heartily of them. The drinking of faculent liquors will also occasion them very violently, as new malt-liquors, or the same when the vessels are almost out; the summer-fruits are also chargeable with these effects, and above all things honey. To all these causes, the habit of the patient greatly concurs, and a general costiveness of the body, and dryness of the bowels, are a frequent occasion of them.

Prognostics in them. Flatulencies often prove an extremely troublesome complaint, and people of an idle sedentary life, especially women, owe a great many uneasy hours to them; and when they grow into a habit, they are always attended with colic pains, cardialgias, anxieties, and suffocatory emotions: it is always to be observed, that the forcible suppression of flatules, brings on much worse complaints, especially in pethoric and sanguine habits; for spastic tonuses of the bowels, and vibrative convulsions, with faintings, are often the consequences of it; and the physician is apt to ascribe soulness or scorbutic habits of the blood, for the symptoms he discovers, which, in truth, are only owing to such a suppression. The *free* discharging of *flatulencies*, on the other hand, is attended with its ill consequence, because it naturally degenerates into a habit.

The suppression of habitual *flatulencies* brings on tumors, indurations of the abdomen, hectics, and a tympanites, and particularly the anxious flatules: these, which might be avoided by eructations, when suppressed, bring on cardialgious and vertiginous disorders of the head.

Method of cure. In this it is first to be considered, whether the flatules have their origin in the bowels, or whether they affect them only by consent, as it often the case in diseases of the neighbouring parts in hypochondriac and hysteric patients, and in persons afflicted with hæmorrhoidal and nephritic complaints, and in cases where women have been ill managed in lyings-in, or in miscarriages: in all these cases, the original cause is to be considered and treated with its proper remedies. But in cases of direct and simple *flatulencies*, the following method will be usually found effectual. The bowels must be carefully kept gently open; for in cases of costiveness, *flatulencies* will always be increased. To this purpose, the common clysters must be given at repeated times, and to these, by way of increasing the stimulus, some of the lesser cenatory is to be added, and some common salt. After these the laxative medicines of the gentler kinds are to be given, and in the intermediate days, the diuretic salts, to attenuate the viscous matter in the bowels; to these nitre and a little cinnabar may be added, and these always have a much better effect than all the hot carminatives usually given. After these, those things are to be given which restore the tone of the parts; such are the bitter and aromatic extracts, with spirit of sale of tartar, spirit of nitre dulcified, and the volatile urinous salts aromatised. Externally stomachic plasters may be applied to the pit of the stomach, as may also the stomachic balsams, such as the oils of *nutmeg*, *carui*, *fennel*, and the like.

The

The general method of treating *flatulencies*, is by the hot aromatics; but these are to be given with great caution; for when the commotions of the blood about the vena porta are in fault, these things always irritate rather than do good: but beyond all things, the too common methods of giving a vomit in these cases is to be avoided; for the discharge of the *flatulencies* upwards is inverted by this means, and then usually follow exquisite pains and tensions of the parts, difficulty of breathing and vertiginous complaints in the head, with noises in the ears, and many other complaints, which are continually increasing, till they are a little eased for the present by an eructation. The happy way of getting rid of these anterior flatuses, is by driving the cause of them downwards, and relieving the loft tone of the parts. Continued exercise is also of the utmost service. Junker's Consp. Med. p. 600.

Dr. Whytt recommends æther and laudanum as the most effectual medicines for expelling wind. He generally gave the laudanum in a mixture with pepper-mint water and tincture of castor, or sweet spirits of nitre: and sometimes opium in pills, with asa fœtida. The dose of æther is a tea-spoonful mixed with two table spoonfuls of water. He also in some cases advises external applications; as equal parts of the antihysteric and stomachic plaster, spread on a piece of soft leather, of such size as to cover a great part of the belly; and a table spoonful of the following ingredients mixed together, and well rubbed on the parts at bed-time; viz. Bate's anodyne balsam, an ounce; the expressed oil of mace, half an ounce; and two drams of oil of mint. For strengthening the stomach and bowels, and lessening the production of *flatulence*, he recommends the Peruvian bark, bitters, chalybeats, and exercise. To remove the costiveness, which often attends windy complaints, four or five of the following pills should be taken every night at bed-time: take of asfa-fœtida, two drams; Socotrine aloes, salt of iron, and powdered ginger, of each one dram; and as much of the elixir proprietatis as will be sufficient to form them into pills. When the body is too open, twelve or fifteen grains of rhubarb, with half a dram, or two scruples, of the Japonic confection, may be taken every other evening with advantage. *Flatulencies* that attend the cessation of the menses are relieved by repeated small bleedings. With regard to diet, tea and all flatulent aliments should be avoided; and as for drink, water, with a little brandy or rum, is not only preferable to malt liquor, but, in most cases, to wine.

FLATULENT, something that has a relation to flatuses, or blasts of wind.

Peas, and most kind of pulse, onions, &c. are *flatulent* foods.

FLAUTINO, in the *Italian Musick*, the name of a small flute or FLAGEOLET.

FLAUTO, in the *Italian Musick*, is used to denote a flute, or the part to be played by that instrument.

FLAUTO, *transforso*, in the *Italian Musick*, a German FLUTE.

FLAW, at *Sea*, signifies a sudden gust of wind, otherwise called *squale*.

FLAX. *Linum*, in *Botany*, a genus of the *pentandria pentagynia* class. Its characters are these: the flower has a permanent empalement, compofed of five small spear-shaped acute leaves; and five large oblong petals, which spread open; and five awl-shaped erect stamina, terminated by arrow-shaped fummits. In the centre is situated an oval germen, supporting five slender styles, crowned by reflex stigmas, and afterwards turns to a globular capsule with ten cells, opening with five valves; in each cell is lodged one oval, plain, smooth seed, with an acute point. There are fourteen species. Miller.

The common *flax* is an annual plant that will grow in any kind of good found land, but that does beft for it, which has lain fome time unplowed. The beft land yields the beft *flax*, and makes the greateft improvement; and upon the whole, it is an excellent commodity, and the tilling and ordering it is fo good a piece of husbandry, that it well deferves to be more frequently practifed amongft us. It is a plant that exhaufts the land very much; on which account it is beft to few it on very rank ground, and not two years together on the fame piece. If the land is fituated in a valley, or the foil has been thrown up by rivers; or if there be water at a fmall depth below the furface, it is thought better. To this fait circumftance it is owing, that Zealand is remarkable for the fineneſs of its *flax*, and that the other provinces of Holland do not fucceed fo well in the culture of this plant. However, M. Du-Hamel obferves, that ftrong land can hardly yield fuch fine *flax* as that which grows on lighter ground; though a moift ftiff foil yields larger quantities, and better feed. The time of fowing is in the latter end of March, when the weather is mild and warm; the land fhould be well prepared, cleared from weeds, and laid even, and the driefl: feafon that can be fhould be chofen for the fowing it. The ground fhould be followed two winters and one fummer; and between each ploughing it fhould be well harrowed, in order to deftroy the weeds, and pulverize the foil. The dung fhould not be laid on till the laft ploughing, when it muft be buried in the ground, and care fhould be taken that the dung be free from weeds. The Livonians, when they clear wood land, burn the wood upon it, and then plough it, and in this ftate prefer it to any other foil for *flax*. The beft way of fowing *flax*-feed is to drill it in equidiftant rows, about ten inches from one another. When the *flax* is thus fown, the ground may be eaſily hoed, to deftroy the weeds, which, repeated twice in dry weather, will keep the ground clean till the *flax* is ripe. Some have recommended feeding the fheep with *flax*, when it is rifen to a good height; but Mr. Miller condemns this as a wrong practice; becaufe, if the fheep gnaw the *flax*, the plants will fhoot up very weak, and never come to half the fize they would have done, if not cropped. *Flax* is fometimes damaged by infects, when it is about three or four inches high; it has been faid that they may be deftroyed by a flight ftrewing of foot, afhes, &c. This dreffing will, at leaft, give vigour to the *flax*, though it fhould not kill the infects.

Two or three buſhels of good feed, fown in broad-caſt, are required for an acre; but half the quantity in drills will produce a greater crop. The thicker the feed is fown, the finer thread will the *flax* produce; but the feed will be of an inferior quality. Towards the latter end of Auguſt the *flax* will begin to ripen, but it muſt not ſtand till too ripe, but muſt be pulled as ſoon as the ſeed grows brown, and bends down the heads.

The beſt ſeed is that brought from the eaſt country, particularly from Riga, whence great quantities are imported into Scotland and Ireland, to the amount of many thouſand pounds ſterling *per annum*. The beſt ſeed is ſhort, roundiſh, firm, oily, heavy, and of a ſhining or clear brown colour; which, though dear, repays the charges with abundance.

Flax, pulled up in the bloom, proves whiter and ſtronger, than if left ſtanding till the ſeed is ripe; but then the ſeed is loſt. However, the thread will be ſtronger when the *flax* is left till the ſeed is ripe, provided it is not left to ſtand too long, but the colour of it will not be ſo good. In Holland, when the *flax* is pulled, it is laid in handfuls on the ground, with the heads towards the ſouth, and thus piled in heaps, when the weather is uncertain; but in dry weather it is ſpread in handfuls on the field, and left for twelve or fourteen days to dry. However, this drying is not neceſſary for the rippling; and therefore, in ſome parts of Brittany, they ripple the *flax* after it has been in the air two or three days; and even one day will be ſufficient, if the weather be dry.

The Siberian perennial *flax* anſwers very well for making common ſtrong linen; but the thread ſpun from this is not ſo fine or white as that produced from the common ſort; but the roots of this kind of *flax* will continue many years, ſo that there will be a great ſaving of culture. As it will require no other care, beſides keeping it conſtantly clean from weeds. The fineſt *flax* is moſt liable to be laid in ſtormy weather; to guard againſt this accident, ſome perſons run across their *flax* field ſtrong border poles fixed to ſtakes; but a better method is to run ſmall ropes across the field, both lengthwiſe and breadthwiſe; for theſe, being faſtened where they interſect one another, and ſupported by ſtakes at due diſtances, form a kind of netting, which is proof againſt almoſt any accident that can happen from tempeſtuous weather.

For the preparations *flax* muſt undergo, to fit it for ſpinning, as pulling, drying, and ſwingling, ſee HEMP. They have a very good way of beating their hemp and *flax* in Derbyſhire, which is this: they make the axle-tree of the main wheel of their corn mills longer than ordinary, and place pins in it to raiſe large hammers, like thoſe uſed in the paper and ſulling-mills; and with theſe they beat the ſtalks, and ſave a great deal of labour. See HEMP.

In the Sweediſh Tranſactions for 1747, we have the following method of preparing *flax* to as to reſemble cotton, in whiteneſs and ſoftneſs as well as in coherency. For this purpoſe, a little ſea-water is directed to be put into an iron pot, or an untinned copper kettle, and a mixture of equal parts of birch-aſhes, and quick-lime ſtrewed upon it. A ſmall bundle of *flax* is to be opened and ſpread upon the ſurface, and covered with more of the mixture, and the ſtrata are to be continued till the veſſel is ſufficiently filled. The whole is then to be boiled with ſea-water for ten hours; freſh water being occaſionally ſupplied in proportion to the evaporation, that the matter may never become dry. The boiled *flax* is

is to be immediately washed in the sea, by a little at a time, in a basket, with a smooth stick; when it is become cold enough to be borne by the hands, it must be well rubbed, washed with soap, and laid to bleach, and turned and watered every day. Repetitions of washing with the soap, expedite the bleaching; after which the *flax* is to be beat, and again well washed. When dry, it is to be worked and carded in the same manner as common cotton, and pressed betwixt two boards for forty-eight hours. It is now fully prepared, and fit for use. It loses in this process near one half of its weight, which is abundantly compensated by the improvement made in its quality.

Flax has one quality not taken notice of by botanical writers, which is, that the herb, infused in water, as in ponds or rivers, as is practised, in order to rot the *stem*, and procure the bark for mechanical purposes, communicates to the water a very poisonous quality; insomuch that cattle which drink of it die, and the fish in such waters are poisoned; it is therefore forbid to be watered in any running stream, or common pond, by 33 Hen. VIII. cap. 17. This plant yields, by means of a retort, a greasy substance, resembling oil of mace, and called by some butter of *flax*.

The seed, which is usually called LINSEED, is emollient, digesting, and ripening; of great use against inflammations, tumors, and impostbumes; and is frequently put into fomentations and cataplasms for those purposes. Cold drawn linseed oil is of great service in all diseases of the breast and lungs; as peripneumonies, pleurisies, coughs, asthmas, consumptions, colics, and costiveness of the belly. It likewise helps the colic and stone, both when taken by the mouth, and given in clysters. The oil by expression is the only officinal preparation.

This oil, when carefully drawn, without the application of heat, has no particular taste or flavour, though in some properties it differs considerably from most of the other oils of this kind; not congealing in winter; not forming a solid soap with fixed alkaline salts; and acting more powerfully, as a menstruum, on sulphureous bodies, than any other expressed oil that has been tried. It is also supposed to be of a more healing and balsamic nature than the other oils of this class. Lewis, Mat. Med. In pleuritic pains, says Ruyschius, Ephem. Germ. An. 6 & 7. he has often experienced linseed oil to be the most successful medicine he could prescribe; for it immediately facilitated respiration, and promoted spitting. In a hæmoptoe also, he exhibited the same oil with the desired success; for by its balsamic and emollient virtue it consolidates the affected parts.

Linseed oil is of such subtile parts, as not to be kept in earthen vessels without transludation. Meyerus de Lusu ferio. Tumors of the belly are very happily cured by the use of linseed oil. Ephem. Germ. An. 3

FLAX, *Carolina*. See POLYPREMUM.

FLAX, *purging*. See LINUM *catharticum*.

FLAX, *toad*, *Linaria*, in *botany*. Its characters are these: the flower has a permanent empalement of one leaf, divided into five parts almost to the bottom, and one petal of the ringent kind, having an oblong swelling tube, with two lips above, and the chaps shut. The upper lip is bind and reflexed on the sides; the lower lip is trifid and obtuse. It hath an oblong nectarium, awl-shaped, and prominent behind, and four stamina, which are included in the upper lip, two of which are shorter than the other; and a roundish germen, supporting a single style, crowned by an obtuse stigma, which afterward turns to a roundish, obtuse capsule, with two cells, filled with small seed. There are seventeen species. Miller.

This is joined by Linnæus to the *antirrhinum*. See SNAP-DRAGON.

The first species of these plants grows in great plenty on the sides of dry banks in most parts of England. It flowers in July and August, and would make an agreeable appearance in gardens, where it might be allowed a place, were it not for its creeping roots, which spread too much. It is one of the simples, in the catalogue of simples, of the College Dispensatory, to be used in medicine. The leaves have a bitterish, and somewhat saline taste; and when rubbed between the fingers yield a faint smell, resembling that of elder.

The whole herb is used, and is of an aperitive and dietetic nature, opening obstructions of the liver and spleen, relieving the dropsy and jaundice, which it carries off by urine. The ointment made with hog's lard, and a good quantity of this herb, is accounted excellent for the piles, being mixed with the yolk of an egg, and applied to the part. James,

The only officinal preparation is the *unguentum linarie*.

FLAX, *Scotland toad*. See TRELISIUM.

FLAX-*plant*, is a name which we may give to a plant that serves the inhabitants of New Zealand instead of hemp and *flax*. Of this plant there are two sorts; the leaves of both resemble those of flags, but the flowers are smaller, and their clusters more numerous; in one kind they are yellow, and in the other a deep red. Of the leaves of these plants, with very little preparation, they make all their common apparel, and also their strings, lines, and cordage, for every purpose, which are so much stronger than any thing we can make with hemp, that they will not bear a comparison. From the same plant, by another preparation, they draw long slender fibres, which shine like silk, and are as white as snow: of these which are very strong, they make their finest cloaths; and of the leaves, without any other preparation than splitting them into proper breadths, and tying the strips together, they make their fishing-nets, some of which are of an enormous size. Hawkesworth's Voyag. vol. iii. p. 749.

The seeds of this valuable plant have been brought over into England; but, upon trial, appeared to have lost their vegetating powers.

The filamentous parts of different vegetables have been employed in different countries for the same mechanic uses as hemp and *flax* among us. Putrefaction, and in some degree alcaline fixivia, destroy the pulpy or fleshy matter, and leave the tough filaments entire. By curiously putrefying the leaf of a plant in water, we obtain the fine flexible fibres, which constituted the basis of the ribs and minute veins, and which form, as it were, a skeleton of the leaf. In Madagascar, different kinds of cloth are prepared from the filaments of the bark of certain trees boiled in strong ley; and some of these cloths are very fine, and approach to the softness of silk, but in durability come short of cotton; others are coarser and stronger and last thrice as long as cotton; and of these filaments they make sails and cordage to their vessels. The stalks of nettles are sometimes used for like purposes even in France; and Sir Hans Sloane relates, in one of his letters to Mr. Ray, that he has been informed by several, that muslin and callico, and most of the Indian linens, are made of nettles. A strong kind of cloth is said to be prepared in some of the provinces of Sweden of hop-stalks; and in the Transactions of the Swedish Academy for 1750, we have an account of an experiment relating to this subject: a quantity of the stalks was gathered in autumn, which was equal in bulk to a quantity of *flax* sufficient to yield a pound after preparation. The stalks were put into water, and kept covered with it during the winter. In March they were taken out, dried in a stove, and dressed as *flax*. The prepared filaments weighed nearly a pound, and proved fine, soft, and white; they were spun and wove into six ells of fine strong cloth. Unless the stalks are fully rotted, which will take much longer time than *flax*, the woody part will not separate, and the cloth will prove neither white nor fine. See Dr. Lewis's notes to Neumann's Chemistry, p. 428, 429.

FLEA, *Pulex*, in *Natural History*, a genus of the *aptera* class of insects; of a roundish compressed figure, with two eyes, six feet formed for leaping, and filiform antennæ; the mouth is bent downwards, and concealed a small sting or piercer. The generation of this familiar vermin affords something very curious, first discovered by Sig. Diacinto Cestoni.

Fleas bring forth eggs, or nits, which they deposit on animals that afford them a proper food; these eggs being very round and smooth, usually slip strait down; unless detained by the piles, or other inequalities, of the cloaths, hairs, &c.

Of these eggs are hatched white worms, of a shining pearl colour, which feed on the scurfy substance of the cuticle, the downy matter gathered in the piles of cloaths, or other the like substances.

In a fortnight they come to a tolerable size, and are very lively and active; and, if at any time disturbed, they suddenly roll themselves into a kind of ball.

Soon after this, they come to creep, after the manner of silk-worms, with a very swift motion. When arrived at their size they hide themselves as much as possible, and spin a silken thread out of their mouth, wherewith they form themselves a small round bag, or case, white within as paper, but without always dirty, and fouled with dust. Here, after a fortnight's rest, the animalcule bursts out, transformed into a perfect *flea*; leaving its cauvine in the bag.

While it remains in the bag it is milk-white, till the second day before its eruption; when it becomes coloured, grows hard, and gets strength; so that, upon its first delivery, it springs nimbly away. Phil. Trans. N° 249.

The *flea* when examined by the microscope affords a very pleasing object. It is covered all over with black, hard and shelly scales, or plates, which are curiously jointed, and folded one over another in such a manner, as to com-

ply with all the nimble motions of the creature. These scales are all curiously polished, and are beset about the edges with short spikes in a very beautiful and regular order. Its neck is finely arched, and much resembles the tail of a lobster; the head also is very extraordinary; for from the snout part of it there proceed the two fore-legs, and between these is placed the piercer or sucker, with which it penetrates the skin to get its food.

Its eyes are very large and beautiful, and it has two short horns or feelers. It has four other legs joined all at the breast. These, when it leaps, fold short one within another, and then exerting their spring all at the same instant, they carry the creature to a surprising distance. The legs have several joints, and are very hairy, and terminate in two long and hooked sharp claws.

The piercer or sucker of the *flea* is lodged between its fore-legs, and includes a couple of darts or lancets, which after the piercer has made an entrance, are thrust farther into the flesh, to make the blood flow from the adjacent parts, and occasion that red round spot, with a hole in the centre of it, vulgarly called a *flea bite*.

This piercer, its sheath opening sideways, and the two lancets within it, are very difficult to be seen, unless the two fore-legs, between which they are hid, be cut off close to the head; for the *flea* rarely puts out its piercer, except at the time of feeding, but keeps it folded inwards; and the best way of seeing it is by cutting off first the head, and then the fore-legs, and then it is usually seen thrust out in convulsions.

By keeping *fleas* in a glass tube corked up at both ends, but so as to admit fresh air, their several actions may be observed, and particularly their way of coupling, which is performed tail to tail; the female, which is much the larger, standing over the male: they may also be thus seen to lay their eggs, not all at once, but ten or twelve in a day for several days successively, which eggs will be afterwards found to hatch successively in the same order. The *flea* may easily be dissected in a drop of water and by this means the stomach and bowels, with their peristaltic motion, may be discovered very plainly, as also their testes and penis, with the veins and arteries, though minute beyond all conception. Mr. Leewenhoeck affirms also, that he has seen innumerable animalcules shaped like serpents, in the semen masculinum of a *flea*. Baker's Microsc. p. 191 and 194.

FLEA-*bane*, in *Botany*, *Conyza*, a genus of the *syngenesia polygamia superflua* class. Its characters are as follow: it hath a compound flower, made up of many hermaphrodite florets, which compose the disk, and female half florets, which form the rays; the hermaphrodite florets are funnel-shaped, and cut into five parts at the brim, and have each five short hairy stamina; in the bottom of each floret is situated a germen. The female half florets, or rays, are funnel-shaped, and cut into three parts at the top; these have a germen. The hermaphrodite and female florets are each succeeded by one oblong seed, crowned with down, sitting upon a plain receptacle, and are included in the empalement. Miller enumerates seventeen species.

The common *flea-bane* stands recommended by the old authors as a remedy for many cutaneous disorders. They had an opinion also, that the smoke of it when burnt in a room destroyed fleas, and other insects.

FLEA-*bane*, *stratæ*, *African*. See TARCHONANTHUS.

FLEA-*bane*, *sweet*. See GROUNDSEL.

FLEA-*bane*, *marsh*, *Indian*. See ELECAMPANE.

FLEA-*wort*, *Psyllium*, in *Botany*, the name of a genus of plants, the flowers and fruit of which are like those of the PLANTAIN, to which Linnæus has joined it; but the stalks are ramose and foliaceous.

The seeds of *psyllium* are recommended by many in jaundices and dysenteries; but the present practice receives it only as a mucilaginous seed.

FLEA-*bitten colour* of a horse is white, spotted all over with dark reddish spots.

FLEAM, a small instrument of pure steel, composed of two or three moveable lancets, for bleeding a horse, or the like.

A case of *fleams* as it is called by farriers, comprehends six sorts of instruments; two hooked ones, called drawers, and used for cleansing wounds; a penknife, a sharp pointed lancet for making incisions; and two *fleams*, one sharp, and the other broad pointed: these last are somewhat like the point of a lancet, fixed in a flat handle, only no longer than is just necessary to open the vein.

Fleams imported, beside the duty on steel, pay each $\frac{25}{100}$ d. and drawback on exportation $\frac{19}{100}$ d.

I here are many surgeons in Germany who bleed, or perform the operation of phlebotomy with this instrument, which they use in this manner: they hold one finger upon the end of it, which serves as a handle, and applying the point to the vein they are to open, strike upon the back over the point with one of the fingers of the other hand, opening the vein much as farriers bleed horses. Others use a spring *fleam*, something like a single point of the scarifying instrument used in cupping; and others employ a sort of instrument in form of a dart; but as the position and size of the veins is different, in different subjects, no instrument will ever be found to useful as the common lancet of a proper size. Houlter's Surgery. p. 274.

FLEDWITE, or FLIGHT-WITE, in our *Ancient Laws*, a discharge, or freedom, from amercements: when one, having been an outlawed fugitive, comes to the peace of our lord and king, on his own accord, or with licence. Rathal.

Others rather take it to denote a mulct, or fine, set upon a fugitive to be reduced to the king's peace.

FLEECE, the covering of wool from off the bodies of sheep.

FLEECE, *the golden*, is famous among the ancient writers. It was this that the Argonauts, under the command of Jason, went in pursuit of to Colchis, a province of Asia, now called Mingrelia.

The mystery of the *golden fleece* is variously explained; either of the profit of the woolstrade to Colchis; or of the gold that they commonly gather there, with fleeces, in the rivers. Arbuth. Diss. p. 224. See ARGONAUTS.

FLEECE, *order of the Golden*. See GOLDEN *Fleece*.

FLEET, a number of vessels, going in company, whether on a design of war, or commerce.

In times of peace, merchants ships go in *fleets*, for their mutual aid and assistance: in times of war, besides this security, they likewise procure convoys of men of war; either to escort them to the places whither they are bound, or only a part of the way, to a certain point or latitude, beyond which they are judged out of danger of privateers, &c.

The admirals of his majesty's *fleet* are classed into three squadrons, viz. the red, white, and blue. When any of these officers are invested with the command of a squadron, or detachment of men of war, the particular ships are distinguished by the colours of their respective squadron; the union is common to them all, and in those of the red squadron it is displayed on a red field; on a white for those of the white squadron, and on a blue field for the blue squadron. A *fleet*, whatsoever be the number of ships of which it consists, is usually divided into three SQUADRONS, and these again, when the ships are numerous, into three DIVISIONS, distinguished by particular flag or pendant, and usually commanded by a general officer. The admiral, or principal officer, commands the centre; the vice-admiral, or second in command, superintends the van-guard; and the operations in the rear are directed by the rear-admiral, or officer next in rank. The most convenient order of a *fleet*, proceeding on a voyage, is that in which it is ranged into three lines or columns, each of which is parallel to a line close-hauled, according to the tack on which the line of battle is designed to be formed. The *fleet* being thus more inclosed, will more readily observe the signals, and with greater ease form itself into the LINE of battle. See ENGAGEMENT.

The Spanish *fleet* sent against England by Philip II. consisted of a thousand vessels. In the East there have been *fleets* seen of three thousand vessels.

Merchant *fleets* generally take their denomination from the place they are bound to; as the Turky *fleet*, East Indis *fleet*, &c.

The Spaniards call simply the *fleet*, or *flota*, a certain number of vessels, belonging partly to the king, and partly to merchants, sent every year to Vera Cruz, a port of New Spain.

The *flota* consists of the captain, admiral, and patach or pinnace, which go on the king's account; and about fifteen ships, from four hundred to a thousand tons, belonging to particular persons. They are all so heavy laden, both going and coming, that they have much ado to defend themselves when attacked. The *fleet* puts out from Cadiz about the month of August, and makes it eighteen or twenty months before its return.

The *fleet* sent annually from the same port to Peru, they call the GALLEONS.

When the two *fleets* put out together, they go in company as far as the Antilles, where they separate: the galleons for Carthagena, and Porto Bello; and the *flota* for Vera Cruz; on their return they join at the Havanna.

Of the two *fleets* the *galleons* are the most richly laden; not but the cargo of the *flota* is also very considerable.

FLEET is also a famous prison in London, thus called from the river Fleet, on the border whereof it once stood.

To this prison persons are usually committed for contempt of the king and his laws; or upon absolute command of the king, or some of his courts, particularly that of chancery; and lastly, for debt.

FLEETING, in *Sea Language*, is the act of changing the situation of a tackle, when the blocks are drawn together; or what is called BLOCK and block by failors. The use of *fleeting* is to replace the mechanical powers into a ſtate of action, and the operation is nearly ſimilar to that of winding up a clock or watch.

FLEGM, FLEGMATIC, FLEGMAGOGUE, &c. See PHLEGM, PHLEGMATIC, &c.

FLEMENEFRIT, FLEMENEFRINTHE, or FLYMENAFRYNTHE, in our *Old Writers*, ſignifies the receiving or relieving of a fugitive or outlaw.

FLEMESWITE. Fleta, who writes of this word, interprets it *habere catalla fugitivorum*.

FLEMINGIANS, or FLANDRIANS, in *Eccleſiaſtical Hiſtory*, a ſect of rigid Anabaptiſts, who acquired this name in the ſixteenth century, becauſe moſt of them were natives of Flanders, by way of diſtinction from the WATERLANDIANS. In conſequence of ſome diſſenſions among the *Flemingians*, relating to the treatment of excommunicated perſons, they were divided into two ſects, diſtinguiſhed by the appellations of Flandrians and Frieſlanders, who differed from each other in their manners and diſcipline. Many of theſe in proceſs of time came *over* to the moderate community of the Waterlandians; and thoſe who remained ſeparate are ſtill known by the name of the old *Flemingians*, or Flandrians; but they are comparatively few in number. Theſe maintain the opinion of Menno, with reſpect to the incarnation of Chriſt, alleging, that his body was produced by the creating power of the Holy Ghoſt, and not derived from his mother Mary.

FLEMISH, or the FLEMISH *tongue*, is that which we otherwiſe call Low Dutch, to diſtinguiſh it from the German, whereof it is a corruption, and a kind of dialect. The *Flemiſh* is the language uſed throughout the provinces of the Netherlands. It differs conſiderably from the Walloon, which is a corrupt French.

There are ſeveral *Flemiſh* tranſlations of the Bible. In the year 1618, it was decreed by the ſynod of Dort, that a new *Flemiſh* verſion ſhould be made of the whole Scriptures; becauſe the old tranſlation, which had been taken from that of Luther, was full of faults. Accordingly, ſeveral perſons, learned in the Greek and Hebrew languages, undertook the work; which was publiſhed with notes in 1637. This Bible is highly valued by the reformed in Holland, &c. Though M. Simon cenſures it as being far from the perfection of a juſt tranſlation.

FLEMISH *bricks*. See BRICKS.

FLESH, *Caro*, in *Anatomy*, a ſimilar fibrous part of an animal body, ſoft and bloody; being that whereof moſt of the other parts are compoſed, and whereby they are connected together.

Fleſh is properly underſtood of ſuch parts of the body where the blood-veſſels are ſo ſmall, as only to retain blood enough to preſerve their colour red.

The ancients accounted five different kinds of *fleſh*; the firſt *muſcular*, *ſinewy*, or *fibular*; as the ſubſtance of the heart, and other muſcles; the ſecond *parenchymous*, as that of the lungs, liver, and ſpleen; the third *viſcerous*, as the *fleſh* of the ſtomach and inteſtines; the fourth *glandulous*, as that of the breaſts, pancreas, tonſils, &c. and the fifth *ſpurious*, as that of the gums, glans of the penis, lips, &c.

The moderns admit only of one kind of *fleſh*; viz. the muſcular, conſiſting of little tubes and veſſels, with blood therein: ſo that *fleſhy* and muſcular parts of the body with them are the ſame thing.

Sometimes, however, they apply the terms to the glands which they call, by way of diſtinction, *glandulous fleſh*. As to the parenchymas, they are now found to be quite other things than the ancients imagined. The lungs are only an aſſemblage of membranous veſicles, inflated with air; the liver a collection of glands, wherein the bile is ſeparated; the ſpleen, a heap of veſicles, full of blood; and the kidneys, like the liver, a maſs of glands for ſeparating of the urine.

FLESH is alſo uſed, in *Theology*, in ſpeaking of the myſteries of the INCARNATION and euchariſt.

The word was *made fleſh*, *Verbum caro factum eſt*.

The Romaniſts hold, that the bread in the ſacrament of the ſupper is turned into the real *fleſh* of Jeſus Chriſt. See TRANSUBSTANTIATION.

FLESH, *fungous*. See FUNGUS.

FLESH is ſometimes alſo uſed by botaniſts for the ſoft pulpy ſubſtance of any fruit, incloſed between the outer rind or ſkin, and the ſeeds, or ſtone; or for that part of a root, fruit, &c. fit to be eaten.

FLESH-*colour*. See CARNATION.

FLESHY *roots*. See FIBROUS *roots*.

FLESUS, in *Aſtrology*, a name uſed by ſome authors for the common FEOURDER; the PASSER *flexuoſus* of moſt writers.

FLET-*milk*, denotes milk that has been ſkimmed, or from which the cream has been taken.

FLEUR-DE-LIS, FLEURETTE, FLEURONNY, and FLEURY, in *Heraldry*. See FLORY.

FLEXIBLE, in *Phyſics*, is applied to bodies that are capable of being bent, or changed from their natural form and direction.

A body is not capable of being inflected or bent, unleſs the whole thereof be at reſt. In bending a body, it conſtitutes, as it were, two levers; and the point it is to be bent in, is a fulcrum: hence, as a moving power, the farther it is from the fulcrum, acquires a greater force; the longer the *flexible* body is, the eaſier it is bent.

FLEXION, in *Anatomy*, &c. is applied to the motion of an arm, or other member, whereby it is bent.

The arm has a motion of *flexion*, and another of extenſion.

The motion of *flexion* is, when the radius and humerus approach each other, and form an angle at the elbows.

FLEXION, in *Geometry*. See FLEXURE.

FLEXOR, in *Anatomy*, a name given to ſeveral muſcles in reſpect of their action; viz. the bending of the members, or joints, in oppoſition to the extenſors, which open and ſtretch them; among which are the following:

FLEXOR *capitis* is a muſcle of the head, called alſo RECTUS *major anticus*.

FLEXOR *carpi radialis*, called alſo *radicus internus*, riſes from the inner protuberance of the humerus; and running along the radius, is inſerted into the upper part of the bone of the metacarpus, which is joined with the fore-finger.

FLEXOR *carpi ulnaris*, called alſo *cubitæus internus*, ariſes tendinous from the inner protuberance of the humerus, and upper part of the ulna, upon which it runs along, till paſſing under the ligamentum annulare, it is inſerted by a ſhort ſtrong tendon into the fourth bone of the firſt row of the carpus. See *Tab. Anat.* (*Myol.*) *fig.* 2. *n.* 24.

Both theſe muſcles bend the wriſt. See ULNARIS *internus*.

FLEXOR *digitorum pedis acceſſorius*, a flat and pretty long fleſhy muſcle, ſituated obliquely under the ſole of the foot, and from its ſituation and figure, formerly called *caro plantæ pedis quadrata*.

It is fixed poſteriorly by one fleſhy portion, in the lower ſide of the os calcis, and in the anterior tuberoſity on that ſide, and by the other in the ligament which joins this bone to the aſtragalus. From thence the two other portions run obliquely to the middle of the ſole of the foot, and there unite in a flat, long, and irregularly ſquare muſcular maſs, which fixed to the outer edge of the faſciculus of tendons of the *flexor longus*, to which it ſerves as a *ſtrainum* in that place.

FLEXOR *pollicis pedis brevis* ariſes from the middle of the cuneiform bone. It is ſhort, thick, and fleſhy, ſeemingly two; and, running over the termination of the peronæus, has a double inſertion in the oſſa ſeſamoidea.

FLEXOR *pollicis pedis longus*. This is a muſcle of the toe; it is derived from the back part of the fibula, with a double order of fibres, and runs tendinous under the inner ankle, and through the channel in the inner part of the bone of the heel, to its inſertion at the extremity of the great toe, on the under ſide.

FLEXOR *profundus*, in *Anatomy*, a name given by Cowper and ſome other writers to the muſcle of the foot, called alſo the PERFORANS *pedis*, and the perforatus by Riolan, and ſome others.

FLEXOR *primi internodii digitorum pedis*. See LUMBRICALES *pedis*.

FLEXOR *ſecundi internodii digitorum manus*. See PERFORATUS *manus*.

FLEXOR *tertii internodii digitorum manus*. See PERFORANS *manus*.

FLEXOR *tertii internodii digitorum pedis*. See PERFORANS *pedis*.

FLEXORES *primi internodii digitorum manus*, are muſcles of the fingers, called alſo *lumbricales manus*. See LUMBRICALES.

FLEXORES *pollicis manus*, are the two muſcles ſerving to bend the thumb.

The firſt, called *flexor tertii internodii*, &c. ariſes from the internal protuberance of the humerus, and part of the radius, by different orders of fibres, and, paſſing under the ligamentum annulare, is inſerted into the third bone of the thumb. The ſecond, called *flexor ſecundi internodii*, &c. ariſes from the bones of the carpus, and annular ligament; and is inſerted into the ſecond bone of the thumb.

FLEXORES *ſecundi internodii digitorum pedis*. See PERFORATUS *pedis*.

FLEXURE, or FLEXION, in *Geometry*, is uſed to ſignify, that a curve is both concave and convex, with reſpect to a given right line, or a fixed point. And the point which

which limits the concavity and convexity, is called the POINT *of contrary flexure*. See RETROGRADATION *of curves*.

As to the method of finding the points of the contrary *flexure* see INFLECTION.

FLIDETHRIFT, or more truly SLIDETHRIFT, is the game we now call *shovel-board*. It is otherwise called *shove-groat*, and is mentioned in the statute 33 Hen. VIII. cap. 9.

FLIE, or FLY, that part of the mariner's compass on which the thirty-two winds are drawn, and over which the needle is placed, and fastened underneath.

FLIGHT, the act of a bird in FLYING; or the manner, duration, &c. thereof.

The FEATHERS of birds are admirably contrived and fitted for the ease and convenience of *flight*.

Almoſt every kind of bird has its particular *flight*: the eagle's *flight* is the highest: the *flight* of the sparrow-hawk and vulture are noble, and are fit for high enterprize and combat. The *flight* of some birds is low, weak, tranſient, and, as they call it, *terra à terra*; the *flight* of the partridge and pheaſant is but of ſhort continuance; that of the dove is laboured; that of the ſparrow undulatory, &c.

The augurs pretended to foretel future events from the *flight* of birds.

FLIGHT. In melting the lead-ore in the works at Mendip, there is a ſubſtance which flies away. In the ſmoke, which they call the *flight*.

They find it ſweetiſh upon their lips, if their faces happen to be in the way of the ſmoke, which they avoid as much as poſſible. This, falling on the graſs, kills cattle that feed thereon; and, being gathered, and carried home, kills rats and mice in their houſes; that which falls on the ſand, they gather, and melt upon a flag-hearth, into ſhot, and ſheet-lead.

FLIGHT, *capon's*, in ſome *Cuſtoms*, is a compaſs of ground, ſuch as a capon might fly over. due to the eldeſt born of ſeveral brothers, in making partition of the father's effects with them, where there is no principal manor in a lordſhip. It is uſually eſtimated by a bow-ſhot.

FLIGHT *of a ſtair-caſe*. See STAIR-*caſe*.

FLIGHT, in *Heraldry*. See VOL.

FLING, in the *Manège*, is the fiery and obſtinate action of an unruly horſe.

To fling like a cow is to raiſe only one leg, and give a blow with it.

To fling or kick with the hind legs. See YERKING.

FLINGING, among *Bowlers*. See BOWLING.

FLINT, *ſilex*, in *Natural Hiſtory*, the name of a genus of ſemipellucid ſtones, the matter of which is a cryſtal, debaſed by an admixture of a peculiar and appropriated earth, which is of a blackiſh grey; always free from veins, but, according to the different quantity and diſpoſition of the earth in its compoſition, ſubject to clouds of a darker or paler colour, and naturally inveſted with a thin whitiſh coat.

Naturaliſts, in general, have accounted various ſpecies of *flint*, but erroneouſly; nature has eſtabliſhed it into a genus of itſelf, and allowed no other ſpecies than one, which is ever compoſed of the ſame matter, and differs only in the proportions of its admixture. When cryſtalline matter is debaſed by earths of other colours, or clouded and veined, it ceaſes to be *flint*, and becomes the pebble, the agate, or the onyx; and for want of attending to this diſtinction, many have deſcribed theſe variouſly-coloured bodies twice over: once under the name of *coloured flints*, and a ſecond time under that of *Engliſh agates*, &c.

The characters of genuine *flint* are, that it is a ſtone of an extremely fine and even texture, of a very uncertain ſurface, ſometimes rough, ſometimes ſmooth; of a colour always, in ſome degree, between blackiſh and whitiſh, unleſs accidentally tinged, as all other foſſils are ſubject to be; very readily giving fire with ſteel; not fermenting with acids. Hill's Hiſt. of Foſſils, p. 508.

Flints are generally found in beds of chalk and ſand, but never forming entire ſtrata of rock, as jaſper does. By long expoſure to air and rain, they ſeem to decay, to loſe their luſtre, and their firmneſs of texture, and to be changed into a white calcareous earth or chalk; and on this account they are almoſt always found covered with a white chalky cruſt. *Flint* belongs to the claſs of vitrifiable EARTHS, becauſe it is uſed in one of the principal ingredients of making GLASS.

The ſparks of fire which are produced by ſtriking *flint* againſt ſteel, are of the number of thoſe things which cuſtom has made familiar to us, but in which we might find much matter of inquiry, if we would give way to reaſon on the ſubject.

The ſtriking fire in this manner has probably been as old as the knowledge of ſteel; and ſince the microſcope has been familiar among us, it has been diſcovered, firſt by Dr. Hook, (See Micrograph. 1665 p. 44.) that theſe ſparks are ſo many ſpherical balls of iron detached by the blow from the maſs, and rendered by the heat a ſort of ſcoriæ. Kemp de Kenvyck, a very ingenious chemiſt, propoſed it as a problem worthy the attempts of the curious to ſolve, and propoſed the whole in theſe words; when a *flint* and ſteel are ſtruck together, if the ſparks are received upon a white paper, they are found to be round maſſes, which examined by the microſcope, are found to be melted and ſcorified or vitrified iron, which will no longer anſwer to the magnet: it is therefore demanded, 1. Which of the two inſtruments contributes moſt to this change in the iron? 2. What ſubſtance it is that is employed to this purpoſe? 3. In what manner the operation is performed? and 4. Why if iron be uſed inſtead of ſteel, the ſparks are very few or none, when with ſteel there are ſo many? Theſe queſtions have appeared almoſt unanſwerable, becauſe people ſcarce knew how to conceive, that iron which requires ſo long continued, and ſo violent a fire to put it in fuſion, could by means only of a ſlight blow, be not only melted, but deſtroyed as it were. The moſt eminent perſons of the time declined engaging in the attempt, and Mr. Muſchenbroeck, from whom a ſolution was expected by many, at length referred the whole to Mr. Reaumur, who had ſome time before publiſhed a treatiſe upon iron and ſteel, and was therefore judged to have moſt conſidered the metal in both thoſe ſtates.

This gentleman accepted the taſk, and attempted the ſolution of the problem by reſolving theſe queſtions. 1. By what means the iron is in this act converted into ſcoriæ? 2. By what methods it can be ſo deſtroyed? 3. How it comes not only to be reduced to ſcoriæ, but to be in a ſtate of fuſion, and truly rendered liquid? and 4. Why iron gives leſs as well as fewer ſparks on colliſion with *flint* than ſteel does? The nature of iron is well enough known for us to be aſſured that it contains a large portion of inflammable matter, and that it is never ductile, but while it has a quantity of that inflammable matter in it, and that when that is wholly taken from it, it becomes friable, and is reduced to a ſort of ſcoriæ, analagous to common vitrified matters.

What much conduces to the explication of the given problem, is, that this inflammable matter contained in iron is very eaſily ſeparated when iron is heated in an open fire; which is evidently ſeen, in that it is impoſſible to heat a bar of iron in a ſmith's forge, ſo much as to make it ready for working or joining with another bar, without reducing its whole ſurface to ſcoriæ, or a friable matter which is all thrown off from the bar by the blows of the hammer.

The ſmaller and thinner a piece of iron is, the more eaſily it is reduced to ſcoriæ, and it is eaſy to conceive from hence, that in pieces extremely ſmall, there requires no more than the once thoroughly heating them to reduce the whole to ſcoriæ; and it is eaſily proved by experiment, that the flame of a candle being applied to a fine ſmall piece of filings of ſteel, will ſoon make it red hot; that if it be then ſuffered to cool and laid on a white paper, it will be found much to reſemble the ſparks thrown off by *flint* and ſteel, and will be reduced to ſcoriæ and be friable under the nail, like a piece of charcoal.

It appears then, that there requires but an inſtant of time to give a red heat to a ſmall particle of iron: and alſo that when that heat has been given, the particle muſt have loſt that inflammable matter which cauſed its ductility, and conſequently muſt be reduced to ſcoriæ; and hence it appears not wonderful, that the very ſmall piece or particle of ſteel which is ſtruck off by the *flint*, ſhould be diveſted of its inflammable matter, and with it of its ductility, by being kept red-hot in the open air, only ſo long as it was falling from the ſteel to the paper that is placed to receive it. The extreme ſmallneſs of the particle gives power for ſo ſhort a heat to deſtroy its inflammable matter, in which its ductility conſiſts; and therefore to reduce it to a matter no longer ductile, that is, into ſcoriæ; and we find that if a parcel of fine ſteel-filings be dropt through the flame of a lamp driven into an horizontal direction by the blaſt of a blow-pipe, they will in the inſtant of their paſſing through that flame, ſparkle and become ignited; and if they are received on a white paper placed underneath, the ſmalleſt particles will be found round and friable, reduced to ſcoriæ, no way differing from the little globules of vitrified ſteel, which are ſtruck off from the *flint* and ſteel in giving fire by their colliſion.

When we have occaſion to melt larger parcels of ſteel or iron, we are obliged to have recourſe to ſuch ſubſtances to mix with them as will replace with increaſe that inflammable matter which the fire drives off: the ſubſtances of

this kind are common sulphur, orpiment, arsenic, and the like; and by means of these, it is soon made to run like lead.

Mr. Reaumur having given these hints for explaining the occasion of iron's being found scorified by the short heat it receives from the collision of *flint* and steel, proceeds to account for the reason why iron yields fewer sparks with *flint* than steel does.

On this occasion he observes, that he accidentally had discovered a new phosphorus of iron, in giving the process of which, great light would be thrown into this subject: the method of making it was this; having melted some antimony in a crucible, he threw in, at several times, twice the quantity of iron reduced into thin plates; the whole soon melted together, and became one fluid matter; when this had been cast into a mould and was become cold, it afforded a long train of sparks on being filed with a common coarse file. The sparks were much larger than those produced by a collision of *flint* and steel, and the larger of them set fire to the paper placed to receive them; but upon examination, these were all found to be melted in the manner of the sparkling particles struck off from steel, not only burnt, but melted, and that more perfectly than the others from the common collision with *flint*. If after all this, it be asked, why steel yields much more numerous sparkles than iron? the answer is plain, that the difference of hardness alone is sufficient to occasion it; but granting even that steel and iron were of equal hardness, steel has the same advantage of iron in this respect, that the before mentioned mixture of iron with antimony has over plain iron, in that it contains much more of the inflammable matter than the iron does, and this inflammable matter is also more equally distributed through all its surface.

It may also be judged, that the *flint* not only contributes by its hardness to the sending off the sparks, but also by its sulphur; what the blow dislodges from it of this kind and puts in violent motion, probably having no small effect both in the fusion and scorification of the metal.

That all *flints* contain a large quantity of sulphur is plain, from the sulphureous smell they afford on being struck together; and the sparks which are produced by striking iron against iron are probably affected in the same manner, by the sulphur of the metal dislodged from the adjoining parts by the blow.

One great proof of the sparks being melted and rendered globular by means of the sulphur of the *flint* is, that sparks may be struck from steel, in the same manner by glass as by *flint*, but in less quantity; these having been received on a paper, were examined by Mr. Reaumur, and were found to be scoriæ, of an irregular figure, having never been melted, and therefore never reduced to the globular shape of the others. In regard to the great change wrought in iron by this operation, or its being, according to the words of Kemp, destroyed, no longer retaining its great character of being attracted by the loadstone, Mr. Reaumur willing to try the experiment before he reasoned upon it, found this assertion not to be a fact, or at least not a general one.

All the several kinds of sparks which he mentions, those produced by the common collision of *flint* and steel, those by dropping steel filings through the flame of a lamp, and even those from the filing of the antimoniated iron, all as readily answering to the loadstone as common filings of *iron*; so that if this case sometimes happen, and iron be liable thus to be destroyed, it is however no general fact, but a very rare and extraordinary one. Memoirs Acad. Scienc. Par. 1736.

FLINTS, in the *Glass-trade*. The way of preparing *flints* for the several operations in the glass-trade is this. Choose the hardest *flints*, such as are black and will resist the file, and will grow white when calcined in the fire. Cleanse these of the white scurf that adheres to them, then calcine them in a strong fire, and throw them while red hot into cold water; wash off the ashes that may adhere to them, and powder them in an iron-mortar, and sift them through a very fine sieve; pour upon this powder some weak aqua fortis, or the phlegm of aqua fortis, to dissolve and take up any particles of iron it may have got from the mortar; stir this mixture several times, then let it rest, and in the morning pour off the liquor, and wash the powder several times with hot water, and afterwards dry it for use. You will thus have a powder for making the purest glass as perfectly fine and faultless, as if you had used rock crystal itself. Cramer's Art of Assaying Metals, p. 432.

The washing off the ferruginous particles with aqua fortis is not necessary when the glass intended to be made is to be tinged with iron afterwards; but when meant to be a pure white, this is the method that will secure success.

FLINT, *to cobble of.*—The art of cutting or rather breaking *flint* stones into uniform figures, was by some supposed to be one of the arts now lost. That it was known formerly appears from the ancient Bridewell at Norwich, from the gate of the Austin-Friars at Canterbury, that of St. John's abbey at Colchester, and the gate that formerly stood near Whitehall, Westminster.

But that the art is not lost, and that the French know it, appears from the platform on the top of the royal observatory at Paris, which, instead of being leaded, is paved with *flint*, in the manner here mentioned. But we know not that this art is any where described. Phil. Trans. N°. 477. p. 521, and Note ibid.

FLINTS, *oil of, liquor of*, a name given by some to a preparation made of four ounces of *flints* calcined and powdered, and mixed with twelve ounces of salt of tartar: these being melted together in a large crucible by a strong fire, run into a glass, which quickly and strongly attracts moisture from the air; and is entirely soluble in water, except a very small portion of earthy matter: this glass being afterwards powdered and set in a cellar, runs into an oil per deliquium; with this and the calx of any metal is prepared one of the *metallic* VEGETATIONS. If any acid be added to the liquor of *flints* so as to saturate the alkali, the *flint* which was kept dissolved in water by means of this alkali will be now precipitated in the form of a fine earth, which earth is entirely soluble by acids.

FLINT *mills*. See MILL.

FLIP, a sort of sailors drink, made of malt liquor, brandy, and sugar, mixed.

FLITTER-*Mouse*, in *Zoology*. See BAT.

FLIX *weed*, in *Botany*, a species of *water* CRESSES, which grows in uncultivated places, and by the side of brooks in many parts of England: it flowers in June, and the seeds, which ripen in August, are greatly recommended by some for the gravel and retention of urine.

FLOAT, or FLEET. See FLOTA, and FLEET.

FLOAT *of a fishing line*, &c. See FISHING-*float*.

FLOAT, sometimes called *catamaran*, also denotes a certain quantity of pieces of timber joined together with rafters athwart, thrown into a river, to be conveyed down the stream; and even sometimes to carry burthens down a river with the stream. The invention of *floats* is of great use; it is said to have been first put in execution at Paris, in the year 1549.

FLOAT-*boards*, those boards fixed to *water*-WHEELS of undershot mills, serving to receive the impulse of the stream, whereby the wheel is carried round.

It is a disadvantage to have too great a number of *float-boards*; because when they are all struck by the water in the best manner that it can be brought to act against them, the sum of all their impulses will only be equal to the impulse made against one *float-board* at right angles, by all the water coming out of the pent-stock, through the opening. So as to take place on the *float-board*. The best rule in this case is, to have just so many, that each of them may come out of the water as soon as possible, after it has received and acted with its full impulse; or, which comes to the same thing, when the succeeding one is in a perpendicular direction to the surface of the water.

As to the length of these *float-boards*, it may be regulated according to the breadth of the stream. See Desaguliers, vol. ii. p. 425.

FLOAT *Grass*, in *Botany*. See GRASS.

FLOATAGES. See FLOTAGES.

FLOATING-*bridge*, a bridge consisting of several boats covered with planks; which ought to be so solidly framed as to bear both horses and cannon. See BRIDGE.

FLOATING-*islands*. See ISLANDS.

FLOATING-*vessels*. See BOAT, VESSEL, &c.

FLOATING, in *Husbandry*, is the drowning or watering of meadows.

FLOCK-*Paper*. See PAPER.

FLOOD, a DELUGE or inundation of waters.

FLOOD is also used in speaking of the TIDE.

When the water is at lowest, it is called *flood*; when rising, *young*, or *old flood*; when at highest, *high flood*; when beginning to fall, *ebb-water*.

FLOOD-*mark*, the mark which the sea makes on the shore, at flowing water, and the highest tide: it is also called *high-water mark*.

FLOOD *Sand*. See SAND.

FLOOK *of an anchor*. See ANCHOR.

FLOORING, in *Mining*, a term used to express a peculiarity in the load of a MINE. The load or quantity of ore is frequently intersected in its course, by the crossing of a vein of earth or stone, or some different metallic substance; in which case the load is moved to one side, and this transient part of the load is called a *flooring*.

FLOOR, in *Building*, the underside of a room, or that part we walk on.

Floors are of divers sorts; some of earth, some of brick, others of stone, others of boards, &c.

Carpenters, by the word *floor*, understand as well the frame work of timber, as the boarding over it.

For brick and *stone* FLOORS, see PAVEMENT.

For boarded FLOORS, it is observable, that the carpenters never *floor* their rooms with boards, till the carcase is set up, and also inclosed with walls, lest the weather should injure the *flooring*. Yet they generally rough-plane their boards for the *flooring*, before they begin any thing else about the building, that they may fit them by to dry and season, which is done in the most careful manner. The best wood for *floorings* is the fine yellow deal well seasoned, which, when well laid, will keep its colour for a long while; whereas the white fort becomes black by often washing, and looks very bad. The joints of the boards are commonly made plain, so as to touch each other only; but, when the stuff is not quite dry, and the boards shrink, the water runs through them, whenever the floor is washed, and injures the ceiling underneath. For this reason they are made with feather edges, so as to cover each other about half an inch, and sometimes they are made with grooves and tenons; and sometimes the joints are made with dove-tails; in which case the lower edge is nailed down and the next drove into it, so that the nails are concealed. The manner of measuring *floorings* is by squares of 10 feet on each side, so that taking the length and breadth and multiplying them together and cutting off 2 decimals, the content of a *floor* in squares will be given. Thus 18 by 16 gives 288 or 2 squares and 88 decimal parts.

FLOORS, *earthen*, are commonly made of loam, and sometimes, especially to make malt on, of lime, and brick-dust, and gun-stall, or anvil-stall from the forge.

Oxblood and fine clay, tempered together, Mr Hugh Platt says, make the finest *floor* in the world.

The manner of making earthen *floors* for plain country habitations is as follows. Take two thirds of lime, and one of coal ashes well sifted, with a small quantity of loam clay; mix the whole together, and temper it well with water, making it up into a heap; let it lie a week or ten days and then temper it over again. After this, heap it up for three or four days, and repeat the tempering very high, till it become smooth, yielding, tough, and clayey. The ground being then levelled, lay the *floor* three with about 2 or 3 inches thick, making it smooth with a trowel: the hotter the season is the better; and when it is thoroughly dried, it will make the best *floor* for houses, especially malt-houses.

If any one would have their *floors* look better, let them take lime made of egg-shells, well tempered with whites of eggs, covering the *stone* about ½ an inch thick with it, before the under *flooring* is too dry. If this be well done, and thoroughly dried, it will look when rubbed with a little oil, as transparent as metal or glass. In elegant houses *floors* of this nature are made of stucco or of plaister of Paris beaten and sifted, and mixed with other ingredients.

FLOOR *of a ship*, strictly taken, is only so much of her bottom as she rests on, when aground.

Such ships as have long, and withal broad *floors*, lie on the ground with most security, and are not apt to heel, or tilt on one side; whereas others, which are narrow in the *floor*, or, in the sea-phrase, *crushed by the ground*, cannot be grounded without danger of being overturned.

FLOOR-*Timbers*, in a *ship*, are those parts of a ship's timbers which are placed immediately across the keel, and upon which the bottom of the ship is framed; to these the upper parts of the timbers are united, being only a continuation of *floor*-timbers upwards.

FLORAL *leaves*. See LEAF.

FLORALES *ludi*, or FLORAL *games*, in *Antiquity*, were games held in honour of Flora, the goddess of flowers.

They were celebrated with shameful debaucheries. The most licentious discourses were not enough, but the courtesans were called together by the sound of a trumpet, and made their appearance naked, and entertained the people with indecent shews and postures: the comedians appeared after the same manner on the stage. Val. Maximus relates, that Cato being once present in the theatre on this occasion, the people were ashamed to ask for such immodest representations in his presence; till Cato, apprised of the reverence and respect with which he inspired them, withdrew, that the people might not be disappointed of their accustomed diversion.

There were divers other sorts of shews exhibited on this occasion; and, if we may believe Suetonius in Galba, c. vi. and Vopiscus in Carino, these princes presented elephants dancing on ropes on these occasions.

The *ludi Florales* according to Pliny, lib. xviii. c. 29. were instituted by order of an oracle of the Sibyls, on the 28th of April; not in the year of Rome 230VI. as we commonly read it in the ancient editions of that author, nor in 17XIV. as F. Hardouin has corrected it, but, as Voffius reads it, in 513. Though they were not regularly held every year, till after 580. They were chiefly held in the night time, in the Patrician-street; Flora will have it there was a temple for the purpose, on the hill called Hortulorum.

The goddess Flora is by some said to be the same with the Chloris of the Greeks. Ovid tells us, that this Flora was a famous courtezan; that having by long enriched herself by prostituting herself to the people of Rome her heirs, on condition that they should celebrate the anniversary of her birth-day, by the games and feasts above mentioned. Some time after the senate, judging such a foundation unworthy the majesty of the Roman people, to ennoble the ceremony, converted Flora into a goddess, whom they supposed to preside over flowers; and so made it a part of religion to render her propitious, that it might be well with their gardens, vineyards, &c. This is the common account: but Voffius de Idolol. lib. i. c. 12. can by no means allow the goddess Flora to have been the courtezan above mentioned: he will rather have her a Sabine deity, and thinks her worship might have commenced under Romulus. His reason is, that Varro, in his fourth book of the Latin tongue, ranks Flora among the deities, to whom Tatius, king of the Sabines, offered up vows, before he joined battle with the Romans. Add, that from another passage in Varro it appears, that there were priests of Flora, with sacrifices, &c. as early as the times of Romulus and Numa.

FLORAL *games*. There is also a kind of *Floral games* observed at this day in France; first instituted in 1324.

The design and establishment were owing to seven persons of condition, lovers of poetry, who about All-saints-day, in 1323, sent a circular letter to all the Provencal poets, called Troubadours, to meet at Thoulouse on May-day following, there to rehearse their poems; promising a prize of a violet of gold to the person whose piece should be judged the best.

The capitouls found the design so good, that it was afterwards resolved, as a council of the city, to continue it at the city-charge; which is still done in a manner that does honour to the place.

In 1325, a chancellor and secretary of the new academy were chosen; and the seven initiators took the quality of maintainers thereof. Two other prizes were afterwards added to the violet; viz. an eglantine for the second prize, and a pansy for the third. It was also decreed, that the person who bore away the first prize, might demand to be made bachelor: and that whoever bore away all three, should be created doctor in the *gay science*, that is, in poetry.

There is a register of these games kept at Thoulouse, which gives this account of their origin; though others represent the matter differently. It was an ancient custom they say, for the poets of Provence to meet yearly at Thoulouse, to confer together, animate their verses, and receive a prize allotted to the best performance. This held till about the year 1540, when a lady of quality left the best part of her fortune to eternize the custom, and bear the expence of prizes; the number of which she increased, ordering an eglantine, a pansy, a violet, and a pink: the three first, a cubit high; and worth fifteen pistoles a piece.

The ceremony begins on May-day, with a solemn mass, music, &c. The corporation attends; and poems are rehearsed every day: the third day a magnificent treat is given by the magistracy, &c. and that day the prizes are adjudged. The three prizes are the reward of three different kinds of compositions; viz. a poem, an eclogue, and an ode.

FLORALIA, in *Antiquity*, a general name for the feasts, games and other ceremonies, held in honour of the goddess Flora.

FLORES *argenti*, in *Natural History*, a name given by some to the earth called by the generality of writers LAC *lunæ*. It has both these names from its being supposed to partake of the nature of silver.

FLORES *martiales*, a name given to a preparation of the nature of what was formerly called *ens veneris*. These flowers are thus prepared: take of washed colcothar, or green vitriol, or of iron filings, one pound; of sal ammoniac, two pounds: mix them, and sublime them in a retort, and mixing again the bottom with the flowers, renew the sublimation till the flowers acquire a beautiful yellow colour. To the residue may be added half a pound of fresh sal ammoniac, and the sublimation repeated, and the same process may be continued as long as the flowers arise duly coloured. Pemberton's Lond. Disp. p. 215.

FLORET, *Flosculus*, in *Botany*, is a little tube expanded at the top usually into five segments, and sitting upon the embryo of a single seed; from the inner part of the *floret* arise five stamina, which, uniting together, form a sheath; from the embryo of the seed arises a style, which passes through the sheath, to which it is connected; and is terminated

minated by a bifid ſtigma, which is generally reflexed. Theſe are hermaphrodite.

FLORET, *floret*, is the diviſion of the baſe, and afterwards expanded in the form of a tongue; theſe generally form the rays of compound flowers, and are female.

FLORID *ſtyle*, is that enriched and heightened with figures and flowers of rhetoric. See STYLE.

Longinus uſes the terms *florid* and *affected* ſtyle indifferently, and lays them down as quite contrary to the true ſublime.

FLORILEGIUM, FLORILEGE, a name the Latins have given to what the Greeks called ανθολογιον, ANTHOLOGY; viz. a collection of choice pieces, containing the fineſt and brighteſt things to their liking.

FLORILEGE is alſo particularly uſed as a kind of breviary, in the Eaſtern church, compiled by Arcadius, for the conveniency of the Greek prieſts and monks, who cannot carry with them, in their travels and pilgrimages, all the volumes wherein their office is diſperſed.

The *florilegium* contains the general rubrics, pſalter, canticles, the horologium, and the office of the feria, &c.

FLORIN is ſometimes uſed for a coin, or real money; and ſometimes for an imaginary money, or money of account.

FLORIN, as a coin, is of diverſe values, according to the diverſe metals, and diverſe countries where it is ſtruck. Pieces under this denomination were anciently very frequent in commerce; at preſent they are leſs common, though there were abundance of them ſtruck in Holland, of Engliſh ſilver, during the war, which was terminated by the treaty of Ryſwick. In all appearance they took their name from the place where they were firſt ſtruck, viz. the city of Florence. Their æra is about the year 1251; though others aſcribe the name to a fleur-de-lis, which was ſtruck on one ſide.

Villani obſerves, that there were gold *florins* in the year 1067, from which time the names FRANK or *florin* became applied to the gold coins, which till that time had been called *ſolidi*, *ſolidoes*. See COIN.

FLORIN, as a *money of account*, is uſed by the Italian, Dutch, and German merchants and bankers, in keeping their books, and making up their accounts. But this *florin* is very diverſe, and admits of different diviſions. See COIN.

FLORIN, or FLORENCE, was alſo a gold coin, ſtruck in England in the eighteenth year of Edward III. of the value of ſix ſhillings.

Camden ſays, it was ſo called, becauſe made by Florentines. Fabian obſerves, the *florins* were not of ſo fine gold as the nobles and half-nobles of that prince.

But what is moſt obſervable is, that Fabian calls the *florin* a penny, value 6*d.* 8*s.* the half *florin*, a halfpenny, value 3*d.* 4*s.* the quarter *florin*, a farthing, value 1*s.* 8*d.* Theſe words are often meet with in old hiſtories and accounts, applied to ſeveral coins, as *royals*, *angels*, &c. where we are therefore only to underſtand by *penny* or *ſterling* the whole, by *obolus* the half, and by *quadrans* the fourth part, or farthing.

By indenture of the mint, in 18 Edw. III. every pound weight of old ſtandard gold was to be coined into fifty *florences* or *florins*, to be current at 6*s.* ſhillings a piece; all which made in tale fifteen pounds; or into a proportionable number of half and quarter *florins*.

FLORINIANI, or FLORINISTI, a ſect of heretics, of the ſecond century, denominated from its author Florinus, or Florinus, a prieſt of the Roman church, depoſed along with Blaſtus, for his errors.

Florinus had been a diſciple of St. Polycarp, along with Irenæus. He made God the author of evil; or rather aſſerted, that the things forbidden by God are not evil, but of his own appointing. In which he followed the errors of Valentinus, and joined himſelf with the Carpocratians.

They had alſo other names given them. Philaſtrius ſays, they were the ſame with the *Carpocratians*. He adds, that they were alſo called *ſeculares*, *monites*, *quia de militibus facti ſunt*, &c. Irenæus calls them *Gentiles*; St. Epiphanius, *Patricianici*; and Theodoret, *Barbelici*, on account of the impurities of their lives. Others call them *Zacchæi*; others *Coddeani*, &c. though for what particular reaſon, it is not eaſy to ſay, nor perhaps would it be worth while to inquire.

FLORIST, a perſon curious or ſkilled in flowers; their kinds, names, characters, culture, &c.

It is alſo applied to an author who writes what is called the flora of any particular place, that is, a catalogue of the plants and trees which are found ſpontaneouſly growing there. The Flora Lapponica of Linnæus, and Flora Virginia of Gronovius, are works of this kind; and theſe authors, as the authors of thoſe works, are properly called *floriſtæ*.

FLORUS, in *Ornithology*, a name by which Aldrovand and ſome other authors have called the bird commonly known with us by the name of the WHINCHAT, a kind of the OENANTHE or ſallow-finch.

FLORY, FLOWRY, FLEURY, FLORETTE, FLEURDE-LISE, &c. terms in *Heraldry*, uſed when the outlines of any ordinary are drawn as if trimmed with, or in the form of flowers, lilies, fleur-de-lis, &c.

Thus, he bears a croſs *flory*, &c. See *Tab. Heraldry*, *fig.* 26.

FLOS, the *flower* of a plant. It is to be obſerved that the ancients ſometimes called the ſtamina or threads in the centre of flowers, the *flos*, and not the petals, which we uſually call ſo. Without underſtanding this, it is not poſſible to underſtand many paſſages in their writings. We find in Aurelian, the roſe called a yellow flower ſtanding in a purple huſk; it is plain by this, that he meant the threads in the middle of that flower, which are of a fine yellow, and are very numerous, by the word flower; and he calls the fine purple petals, which we eſteem the flower, only the huſk of the flower. In this ſenſe, Virgil is explained to mean the common broom by the name amello; he ſays it has a yellow flower, and purple leaves at the bottom; and they ſuppoſe that he meant the ſtamina or threads, which in the broom are yellow, by the name flower; and the calyx or cup of the flower, which is a purple, by this expreſſion of leaves at the bottom. The ancients in general do not ſeem determined as to what they would have underſtood by the word *flos*. In the narciſſus, Pliny calls the cup that yellow part which occupies the centre, and the whitiſh leaves that ſurround it, the flower. Pliny has been cenſured for calling this part of the flower the cup; but he does not by this mean to confound it with the green leaves in the generality of plants which ſurround the flower; he only calls it thus in reſemblance to the cups out of which they drank in their feſtivals.

FLOS *æris*. See *Flos*.

FLOS *ambarvalis*, in *Botany*, a name given by ſome to the polygala or MILKWORT.

FLOS *argenti*. See FLORES *argenti*.

FLOS *Aſiæ*, in *Natural Hiſtory*, a name given by Swenkfeld, and ſome other writers, to that fait which is found on the ſurface of the earth in ſome parts of Aſia in form of an efflorescence, and is called the *Smyrna ſoap earth*.

This ſalt is evidently the ſame with the nitre of the ancients. It will ferment with any acid, in the manner of our pot-aſh, or other fixed ſalts, made by fire; and with oil or any fatty ſubſtance, boils into a ſoap. Euelius gives us a great many different places for its production, from which he diſtinguiſhes it into ſeveral kinds; all theſe lie in the eaſtern parts of the world; but to theſe Wormius adds, that it is found in New Spain. It is always eaſy to be known, however, in whatſoever place it is found, being a native alkali ſalt, perforated like a ſponge, and of a frixial taſte. Its principles ſeem to be a marine and an urinous fait.

That it contains a marine ſalt ſeems manifeſt from this, that it has the ſame taſte in ſolution, or nearly ſo, with marine ſalt; that the particles of it when congulating in the evaporated water in which they were diſſolved, firſt riſe to the top of the ſurface, as thoſe of common ſalt do, and that it is always of a ſpongy texture, or full of holes, which is always the caſe with thoſe things in which the common ſalt makes a part, its natural concretions being hollow pyramids. Its containing an urinous ſalt is plain, from its producing with ſalt of tartar the ſame ſort of ſpirit that ſal ammoniac does, when mixed with that fixed ſalt.

FLOS *cæli*, the *flower of the heavens*, a name given by the alchemiſts to the NOSTOCH, which often appearing after rain, was ſuppoſed to fall from heaven. See FLOS *terræ*.

FLOS *martialis*. See FLORES *martiales*.

FLOS *ſalis*. The flower of ſalt flows down with the Nile, and is alſo found on the ſurface of ſome lakes. It is to be choſen of the colour of ſaffron, ſomewhat of a rank ſmell like garum, of a biting taſte, and of a fatiſh ſubſtance. What is coloured with minium, or is grumous, is to be rejected: beſide, what is pure and genuine is not to be diſſolved but in oil; whereas what is adulterated is partly diſſoluble in water.

It is effectual againſt malignant and phagedenic ulcers; noma in the pudenda, and purulencies in the ears: it alſo cures dimneſs of ſight, and removes ſpecks and albugos from the eyes. It is mixed with plaiſters and ointments, as alſo with oil of roſes, for the ſake of the colour it communicates to them. Taken inwardly, in wine or water, it provokes ſweat, diſturbs the belly, and incommodes the ſtomach. It is alſo an ingredient in acopa and ſmegmata, for extenuating the hair. In general it is of an acrimonious and pyrotic quality, as are all ſalts themſelves. Dioſcor. lib. v. cap. 129.

FLOS *terræ*, *flower of the earth*, a name given by ſome of the

the chemical authors to the MERCURY, a remarkable plant, which reſembles the common grass cyperwood, but that it is thicker and more like a reed. It ſuddenly appears no grass or weeds and gardens, after rain; and the alchemists, who knew not what to think of its origin, ſuppoſed it to contain an univerſal ſpirit, capable of turning metals into gold. It is a very ſingular plant, being no way fixed to the ground, nor having any roots, but imbibing its nutritious juices from the humidity of the air, as the ſea-plants do theirs from the ſea-water.

FLOS *tentaline*, in *Botany*, a name given by Tournefort, and many others, to the genus of its fifteenth ſection, called alſo lunes lonicæ, and known by the name of the *caprifolium*, or honeyſuckle.

FLOSCULOUS, in *Botany*, a term uſed by Mr. Tournefort, and others, to expreſs ſuch flowers of plants, as are compoſed each of a great number of ſmaller flowers placed cloſe to one another, and enclоſed in the ſame common cup; each of theſe ſmaller flowers conſiſts of one petal, which is ſlender and hollow, and wider than the bottom, and uſually divided into many ſegments, which ſometimes are diſpoſed in the form of a ſtar. Each of theſe flowers ſtand upon an embryo, or young fruit, from which there grows a capillament, which reaches beyond the flowers. Theſe embryos are lodged in the bottom of the cup, which is called by authors the *thalamus* of the flower, and finally become ſeeds winged with down, or ſometimes without that, and ſometimes armed with prickles. All thoſe that are the flowers of *thiſtles, knapweed, &c.* See *Tab.* IX. *Botany, Claſs* 19.

FLOTA, or FLOTA, *Port.* a name the Spaniards give particularly to the fleet which they ſend annually from Cadiz, to the port of Vera Cruz, to fetch thence the merchandizes gathered in Mexico for Spain. It conſiſts of the captain, admiral, and patach, or pinnace, which go on the king's account; and about fifteen ſhips, from four hundred to a thouſand tons, belonging to particular perſons. They let out from Cadiz about the month of Auguſt, and are of ſtrength to convoy merchantmen before they return.

Theſe ſent to fetch the commodities prepared in Peru, are called galleons.

The name *flotta* is given to a number of ſhips, which get before the reſt in their return, and give information of the departure and cargo of the *flota* and galleons.

FLOTAGES, all ſuch things as are floating on the top of the ſea or great rivers, a word chiefly uſed in the commiſſions of water-bailiffs.

FLOTSON, FLOTSAM, or FLOATSAM, a term ſignifying any goods loſt by ſhipwreck, and ſwimming on the top of the water; which, with *jetſon* and *lagan*, and *derret*, are given the lord high admiral, by his letters patent.

Jetſon is what is caſt out of a ſhip, being in danger of a wreck, and beaten to the ſhore by the waters, or caſt on ſhore by the ſeamen. *Lagan*, or *ligan*, is that which lies in the bottom of the ſea. *Derret* are goods due to ſeveral perſons by compoſition.

FLOUNDER, in *Ichthyology*, the Engliſh name of the fiſh called by the generality of authors *pleſſe ſurmiſſile*, and *paſſer*. According to the new ſyſtem of Artedi, this is a ſpecies of the PLEURONECTES, or FLAT-FISH.

It is diſtinguiſhed from other fiſh of that genus by a row of ſmall ſharp ſpines, that ſurround its upper ſides, and are placed juſt at the junction of the fins with the body; another row marks the ſide-line, and runs both way down the back. The colour of the upper part of the body is a pale brown, ſometimes marked with a few obſcure ſpots of dirty yellow; the belly is white. The *flounder* inhabits every part of the Britiſh ſea, and even frequents our rivers at a great diſtance from the ſalt-waters. It never grows large in our rivers, but is conſiderably ſmaller than thoſe that live in the ſea.

FLOUR, the meal of any grain, but more particularly of wheat; ground and ſifted for the purpoſe of food.

The grain itſelf is not only ſubject to be eaten by inſects in that ſtate, but when ground into *flour*, it gives birth to another race of deſtroyers, who eat it unmercifully and increaſe ſo faſt in it, that it is not long before they wholly deſtroy the ſubſtance. The ſmall *flour* is moſt liable to breed them, eſpecially when ſtale or ill prepared; in this caſe, if it be examined in a good light, it will be perceived to be in a continual motion; and on a nicer inſpection, there will be found in it a great number of little animals of the colour of the *flour*, and very nimble. If a little of this *flour* be laid on the plate of the double microſcope, the inſects are very diſtinctly ſeen in great numbers, very buſy and lively, continually crawling over one another's backs, and playing a thouſand antic tricks together; whether for diverſion or ſearch of food, it is not to be eaſily determined. Theſe animals are of an oblong ſlender [illegible] and are furniſhed with a kind of trunks or [illegible] by means of which they take in their [illegible] is compoſed of ſeveral rings. [illegible] among the magazines of *flour* [illegible] other public uſes; a ſmall [illegible] a parcel of this valuable commo[illegible] preſerve them but, and they increaſe [illegible] method of preventing the total [illegible] make it up into bread as ſoon as [illegible] to prevent their breeding in the *flour* [illegible] ſtamp; nothing [illegible] than *flour*, and yet nothing is [illegible] ſhould be always carefully and [illegible] it is put up, and the barrels [illegible] to be put; then if they are [illegible] warm and dry, they will preſerve [illegible] never does any hurt, though [illegible] ſpoils it. See *Meal*.

FLOWER, in *Botany*, [illegible] parts of plants are more known than their [illegible] definitions given by different authors of the [illegible] very various, and are very neceſſary to be explained in order to the underſtanding of theſe works.

Jungius defines it to be the moſt tender part of a plant, remarkable for its colour or form, or for both, and cohering with the fruit. But this author acknowledges, that there are ſeveral plants, whoſe *flowers* are produced remote from the fruit, and therefore not comprehended in his definition. Mr. Ray ſays, in very vague terms, that the *flower* cohere for the moſt part with the rudiments of the fruit. Tournefort defines it to be a part of a plant very often remarkable for its peculiar colours, for the moſt part adhering to the young fruit, to which it ſeems to afford the firſt nouriſhment, in order to expliſcate its moſt tender parts. But this is a mere indeterminate definition than the former, from its looſe mode of expreſſion. Pontedera defines it to be a part of a plant, unlike the reſt in form and nature. If the *flower* has a tube, it adheres to, or is fixed very near to the embryo, to the uſe of which it is ſubſervient; but if the *flower* has no tube, then its baſe does not adhere to the embryo. This is ſcarce intelligible, except to the expert botaniſt, and may be made to comprehend ſome parts of plants by no means to be underſtood by the name *flower*. Juſſieu defines it to be compoſed of chives, and a piſtillum, and to be of uſe in the generation of the plant; but this is too imperfect, as there are many plants in which the piſtillums is found at a great diſtance from the chives, and many *flowers* which have no piſtillum, and many others which have no chives. Vaillant ſays, that *flowers* are the organs which conſtitute the different ſexes of plants, which are ſometimes found without any covering; and the petals, which moſt of them have, are no way eſſential to their uſe, but are merely intended as covers for them; but yet as theſe cruſts and coverings are the moſt conſpicuous and moſt beautiful parts of the *flower*, theſe are to be called *flowers*, whatever be their form, ſtructure, or colour; and whether they contain the organs of both ſexes in each individual, or only one, or even ſome part depending on one of them, provided they are not of the ſame figure with the leaves of the plant.

The ſhorteſt and moſt exact definition, however, ſeems to be Martyn's; which is, that *flowers* are the organs of generation of both ſexes, adhering to a common placenta, together with their common covering; or of either ſex ſeparately with its proper coverings, if it have any.

The parts of *flowers* are, 1. The ovary, which is the rudiment of the fruit, and is therefore properly the female organ of generation. 2. The ſtyle, which is a body accompanying the ovary, either ariſing from the top of it or ſtanding as an axis in the middle, with the embryos of the ſeeds round it. 3. The ſummits, called alſo apices and antheræ, which are thoſe bodies that contain the prolific powder, analogous to the male ſperm in animals, and generally hung upon ſlender threads, which are called the chives. 4. The petals, commonly called the *flower* leaves, which are thoſe tender fine-coloured leaves which are generally the moſt conſpicuous part of a *flower*. 5. The empalement or calyx, which is formed of thoſe tender leaves which cover the outer parts of the *flower*. Theſe *flowers*, according to the number of their leaves or petals, are called monopetalous, or one-leaved; dipetalous, or two-leaved, and ſo on.

The ſtructure of the different *flowers* is very various; but Dr Grew has obſerved, that the far greater number of them have the empalement, the foliation, and the ſeries of chives, &c. Mr. Ray accounts, that every perfect *flower* has the petals, ſtamina or chives, apices or ſummits, and the ſtyle or piſtil; and ſuch as want any of theſe parts he calls imperfect *flowers*. The greater num-

ber of plants have a *flower* cup, which is of a firmer ſtructure than their leaves, and ſerves for their ſupport.

Flowers are diſtinguiſhed into three kinds, the male, the female, and the hermaphrodite. The male *flowers* are thoſe which have the ſtamina, but bear no fruit; the female are ſuch as contain the piſtillum, this piſtil is ſucceeded by the fruit, and theſe are therefore called the fruitful or bearing *flowers*; and the hermaphrodite are ſuch as have in them the organs of both ſexes in each individual, and of this ſort are the generality of *flowers*, particularly the lily, tulip, daffodil, roſemary, ſage, &c. See FRUCTIFICATION.

The ſtructure of parts is much the ſame in thoſe where the ſexes are divided; the difference between them conſiſts in this, that the ſtamina and apices, i. e. the male parts, in theſe are ſeparated from the piſtils; being ſometimes on the ſame ſtalk, and ſometimes on different ones.

Among the plants which bear both male and female parts on the ſame plant, but at a diſtance from each other, are reckoned the cucumber, melon, gourd, Turky-wheat, turnſol, walnut, oak, beech, fir, alder, cypreſs, cedar, juniper, mulberry, plantain, &c.

Thoſe in which the male and female parts of the *flowers* are borne on different plants, the willow, poplar, hemp, mercury, ſpinage, nettles, and hops. Miller.

Mr. Ray divides *flowers* into *perfect* and *imperfect*.

FLOWERS, *perfect*, he accounts all ſuch as have the petala, though they ſhould want the ſtamina; but this is a very erroneous opinion. Theſe he ſubdivides into *ſimple*, which are thoſe not compoſed of other ſmaller ones, and which uſually have but one ſingle ſtyle; and *compounded*, which conſiſt of many foliculi, all making but one *flower*.

FLOWERS, *ſimple*, are either *monopetalous*, which have the body of the *flower* all of one entire leaf, though ſometimes cut, or divided, a little way, into many ſeeming petala, or leaves; as the borrage, bugloſs, &c. or,

FLOWERS, *polypetalous*, thoſe which have diſtinct petala, and thoſe falling off ſingly, and not altogether, as the ſeeming petala of the monopetalous *flowers* always do.

Both theſe are further divided into *uniform* and *diſform flowers*.

The former have their right and left-hand parts, and the forward and backward parts all alike; but the diſform have no ſuch regularity: ſuch are the *flowers* of ſage, dead-nettle, &c.

FLOWERS, *monopetalous diſform*, are likewiſe further divided into

FLOWERS, *ſemibilabiate*, thoſe whoſe upper part reſembles a pipe, cut off obliquely; as in the *orithalumia*.

FLOWERS, *labiate*, thoſe either with one lip only, as in the *acanthium* and *ſerratula*; or with two lips, as in the far greater part of the labiate *flowers*.

In theſe the upper lip is ſometimes turned upwards, and ſo turns the convex part downwards, as in the chamæciſſus, &c. but moſt uſually the upper lip is convex above, and turns the hollow part down to its fellow below, and ſo repreſents a kind of helmet, or monk's hood; whence theſe are frequently called *galeate*, *cucullate*, and *patriciate flowers*.

Such are the *flowers* of the *lamium*, and moſt of the verticillate plants.

Sometimes alſo the *labium* is entire, and ſometimes jagged or divided.

FLOWERS, *cornicalate*. Theſe are ſuch hollow *flowers* as have on their hinder part a kind of ſpur, or little horn; as in the *linaria*, *delphinium*, &c. and the *cornicabra*, or *cukoo*, is always impervious at the tip or point.

FLOWERS, *compound*, called alſo *compoſite*, and *aggregate flowers*, are ſuch as conſiſt of many little *flowers*, concurring to make up one whole one; each of which has its ſtyle, ſtamina, and adhering ſeed, but all are contained within one and the ſame calyx, or perianthium.

This *compound flower* diſtinguiſhes a large genus of plants, which Mr. Ray divides thus. Herbs having *compounded* or *aggregated flowers*, are,

1. Such as have a *plain-leaved flower* naturally, and for the moſt part full; and having their whole body milky (yielding a milky juice on cutting them); and theſe have their ſeeds,

Firſt, pappous, or winged; that is, having a little lanugo adhering to each ſeed, by which the wind can eaſily carry it from place to place: ſuch are the *lactuca*, *tragopogon*, *ſonchus*, *dens leonis*, *hieracium*, and the *piloſella*.

Secondly, ſuch as have a ſolid ſeed, without any pappus or down upon them; as the *erygium luteum*, *ethereum*, *lampſana*.

2. Such as have a *diſcous flower*: i. e. one compoſed of many ſhort, thick, compoſited *floſculi* (which ſome, by miſtake, call *ſtamina*) fet together, ſo as to make one flat, or hollowiſh ſuperficies: and theſe are alſo either ſuch as have their ſeeds,

Firſt, pappous, as the *roſea*, *paterſon*, *coelina*, *balſamita*, *artemiſia*, *tanacetum*, *abſinthium*, *ſtæchas citrina*, *jacea*, *ſcabioſa*, *eupatorium*, *ſolidago*, *aſtra-cha vulgaris*, *gnaphalium montanum*, and *Alexandrinum*.

Secondly, ſuch whoſe ſeeds are ſolid, and not pappous; as the corymbiferous herbs.

Their doſk is ſometimes radiated, when there is a row of petala ſtanding round in the diſk, like the points of a ſtar; as in the *matricaria*, *chamæmelum*, &c.

And ſometimes naked, having no ſuch radiating leaves round the limb of its diſk; as in the *tanacetum*.

They are likewiſe diſtinguiſhed into *pauciflous*, and *ſtriatæ*.

FLOWERS, *planiſolious*, are thoſe which are compoſed of plain *flowers*, ſet together in circular rows, round the centre, and whoſe face is uſually indented, notched, uneven and jagged; as the *ſtæchas*, *ſonchus*, &c.

FLOWERS, *ſtriatæ*, are thoſe which are compounded of many long, hollow, little *flowers*, like pipes, all divided into large laps at the ends.

FLOWERS, *imperfect*, are ſuch as want the petala, and are called likewiſe *ſtamineous*, *apetalous*, and *capillaceous flowers*.

Thoſe which hang pendulous by fine threads, like the juli, are by Tournefort called *amentaceous*; we call them *catkin-like*. Theſe are Mr. Ray's principal diſtinctions of *flowers*; but other botaniſts furniſh other diviſions and denominations of them; and Mr. Tournefort, in particular, has formed the various claſſes of plants according to the diſpoſition and ſtructure of the *flower*. See *Tab.* VIII. IX. and X. of *Botany*. See BOTANY, and FRUCTIFICATION.

FLOWERS, *amentaceous*. See AMENTACEOUS, and *Tab.* X. of *Botany*, *Claſs* 19.

FLOWERS, *anomalous* or *irregular*, are either monopetalous or polypetalous. The irregular monopetalous *flower* is that in which the petal is divided into unequal ſegments. Theſe are called by Linnæus ringent *flowers*. An irregular polypetalous *flower* is that in which the petals do not agree in figure and poſition. See *Tab.* VIII. *Claſs* 3. and *Tab.* IX. *Claſs* 12.

FLOWERS, *apetalous*. See APETALOUS, and *Tab.* X. *Claſs* 15 and 18.

FLOWERS, *campaniform*, are compoſed of one leaf, and formed into the ſhape of a bell, but with ſome differences in the figure, which conſtitute four ſubordinate ſpecies. 1. The *bell-flower*, ſimply ſo called, which approaches to no other figure but that expreſſed by the name. 2. The tubular narrow kind, which is always conſiderably long. 3. The expanded kind, which opens very wide at the extremity, and repreſents in ſome degree a diſh or baſon. And, 4. The globular *bell-flower*, the mouth of which is narrower and ſmaller than the belly. Tourn. Inſt. p. 76. See *Tab.* VIII. *Claſs* 1.

FLOWERS, *caryophylleous*. See CARYOPHYLLEOUS, and *Tab.* IX. *Claſs* 8.

FLOWERS, *cruciform*, are thoſe conſiſting of four petals, or leaves, diſpoſed in form of a croſs.

Some of theſe *flowers* have a cup, others have not: thoſe which have cups, uſually have them compoſed of four leaves, and placed in the ſame order and direction with thoſe of the *flower*. Of this claſs of plants are the cabbage, ſocket, wall-*flower*, &c. Tourn. Inſt. p. 210. See *Tab.* VIII. *of Botany*, *Claſs* 5.

FLOWERS, *cucurbitaceous*. See CUCURBITACEOUS.

FLOWER, *diſcous*. See DISCOUS.

FLOWERS, *floſculous*. See FLOSCULOUS, and *Tab.* IX. *Claſs* 12.

FLOWERS, *headed*, are thoſe that are compoſed of ſtamina and ſemiflorets, collected into a roundiſh head, and incloſed in one common ſcaly empalement.

FLOWERS, *infundibuliform*, are ſuch as reſemble the figure of a funnel, i. e. are broad and ample at top, and contracted into a neck at bottom: ſuch is that of the bear's ear, or auricula. See *Tab.* VIII. *of Botany*, *Claſs* 2.

FLOWERS, *labiated*. See LABIATED *flowers*, and *Tab.* VIII *of Botany*, *Claſs* 4.

FLOWERS, *leguminous*, are thoſe of leguminous plants. Theſe bear ſome reſemblance to a flying butterfly; for which reaſon they are alſo called *papilionaceous flowers*.

FLOWERS, *liliaceous*. See LILIACEOUS, and *Tab.* IX. *of Botany*, *Claſs* 9.

FLOWERS, *luxuriant*, are *flowers* ſo called, when ſome of the parts of fructification are augmented in number, and others thereby excluded; and theſe are again ſubdivided into *multiplicate flowers*, when by the increaſe of the corolla only a part of the ſtamina is excluded; *full flowers*, when the corolla is ſo far multiplied as to exclude all the ſtamina; and *proliferous flowers*, when one grows out of another; and this happens two ways; either from the centre, when the piſtil ſhoots up into another *flower*, ſtanding on a ſingle pedunculs; and from the ſide, when many pedunculate *flowers* are produced out of one common calyx.

FLOWERS, *monopetalous*. See MONOPETALOUS, and *Tab.* VIII. *of Botany, Class* 1, 2, 3, and 4. and *Tab.* X. *Class* 20.

FLOWERS, *motiles*, are the receptacle of the *hermaphrodites*. Linnæus confines the term to those *flowers* that want the corolla, though they ought to be furnished with it; and this defect he ascribes chiefly to the want of sufficient heat.

FLOWERS, *papilionaceous*, resemble a butterfly with its wings elevated, and consist of four parts, whereof the uppermost is called *vexillum*, or standard; and the two next *alæ*, as resembling the bottom or keel of a boat: these between the two are called *lateral* leaves, or *ale*.

From the bottom of the calyx arises a pistil, which is encompassed with a sheath, or cover, fringed with filaments. This pistil always becomes the fruit, and is usually called the *pod*, in Latin, *siliqua*. See *Tab.* IX. *Class* 10. and *Tab.* X. *Class* 22.

FLOWERS, *radiated*. See RADIATED, and *Tab.* X. *Class* 14.

FLOWERS, *reflexous*. See ROSACEOUS, and *Tab.* IX. *Class* 6. and *Tab.* X. *Class* 21.

FLOWERS, *semiflosculous*. See SEMIFLOSCULOUS, and *Tab.* IX. *Class* 13.

FLOWERS, *staminous*, are such as have no petals, but consist wholly of stamina or threads, with spaces at top. See STAMINEOUS, and *Tab.* X. *Class* 15.

FLOWERS, *verticillate*, or *whorled*, are those ranged, as it were, in circles, rings, or rays, along the stalks, at the base of the leaves: such are those of horehound, clary, &c.

FLOWERS, *umbelliferous*, are those with several leaves disposed in manner of a sole; and which entire essentially become a fruit of two seeds, joined, before they come to maturity; but afterwards easily separated asunder.

They have this denomination, because they are generally sustained by a number of pedicles, subtile, proceeding from the same centre, are branched all around, like the flinks of an umbrella. See *Tab.* IX. *Class* 7.

Of this kind are the *flowers* of fennel, anniseed, &c.

FLOWERS, *colours of*. It is generally agreed among the chemists, that all colours arise from sulphurs, and that they differ according to the different admixtures of salts with these sulphurs. Perhaps on these principles, it may be possible to form some rational conjectures in regard to the origin of colours in the *flowers* of plants. We know very well that the *flowers* of all plants abound in an essential oil or sulphur, to which, according to this doctrine, their colours may be rationally supposed to be owing; and though this oil should be proved to be the very same substance in all, yet their variety of colours may be accounted for from it, since we find that one and the same oil, the essential oil of thyme, according to Mr. Geoffroy's experiments, may be tinged to all the colours that we find in the different *flowers* of plants, from white to deep black, with all the shades of red, yellow, purple, blue, and green, by mixing it with different substances: and by the same token, the essential oil of plants, while contained in their *flowers*, may by the different mixtures they meet with, give them all their beautiful variety of colours. See *Essential* OILS.

We know that the infusions of *flowers*, and of other parts of plants, become red on being mixed with acids, and green on being mixed with alkalies; and there is no reason to doubt, but that it is the sulphureous part of the vegetable in these infusions which thus changes colours on these mixtures. This, however, ought to be proved possible, before it is allowed in argument.

This proof is given in the change of colours before mentioned, which are produced in oils merely by the admixture of different salts; and as all the colours in these are the regular effects of certain combinations, there is great reason to believe, that in those plants where *flowers* give the same colours, there may be the same combinations.

The principal colours of plants, and their several parts, are green, yellow, red, purple, blue, white, black, and transparent whitifh tints; all the others are produced by different combinations of these. The green, which is the common colour of the leaves of plants, is probably the effect of an oil rarefied in that part of the plant, and there mixed with the fixed and volatile salts of the sap, which remain entangled by the earthy particles after most of the aqueous humidity is evaporated, and by that means become in a state to act upon the oil. A clear proof of this is, that if the leaves are covered up in such a manner, that the aqueous humidity of the sap cannot evaporate itself, the oil and salts cannot act upon one another as they naturally would, but becoming diffused among so great a quantity of water, lose the colour they would otherwise have obtained together, and become whitifh or transparent. This is seen in the obvious instance of succory and celery, the leaves of both which plants, though naturally green, become white by being covered up with earth by the gardiners.

The leaves of both plants and trees usually turn red in autumn or on the attack of the first frosts; the reason of which is, that the fixed salts, on the leaving conftringent by the cold, the oils are exalted in the vessels of the leaves, or at least their circulation is greatly interrupted; and being diluted with water, which naturally grows four, the acidity of this alkali takes off the green colour, produced by the alkaline oil. The sap brings on a red colour, in the vegetable reason that the essential oil made green by a mixture of oil of tartar, is again changed to red, by adding to it a proper quantity of distilled vinegar. Where the reader is referred to common experiments the acids of the mineral kingdom turning the infusion of *flowers* red, as they do by the reading of these experiments to be only by destroying the blue, brown, or other colours of the alkaline tints of the plant had made with the infusion.

All the shades and degrees of yellow and saffron colour in the *flowers* of plants, seem wholly owing to a mixture of an acid in their juices, with their essential oil; as the oil of thyme, which is that has very little colour, is made to pass through all their shades of colours, only by digesting it with distilled vinegar. From the digesting the volatile alkaline result as spirit of sal ammoniac and urine, with the same oil, it appears that all the shades of red, from the palest flesh-colour, to purple, and even to the violet blue, are only owing to the different admixtures of an alkaline volatile salt of the animous kind, united in different manners with their essential oils.

Black, which is a very uncommon colour in *flowers*, and which in them ought to be regarded only as a very deep violet, seems the effect of an addition of an acid juice to thereof, steadily turned purple or violet colour by a volatile alcali.

All the shades of blue and purple seem also, by the analogy of the same experiments, to be only the effects of mixtures of alkalies of the fixed and volatile kind, with the oils of plants; since these colours are all produced in those experiments, by mixing the spirit of sal ammoniac, and the oil of tartar with oil of thyme.

The bright green of some *flowers* seems also to be produced by the same salts, only acting on oils more rarefied. For the oil of thyme of a purple violet-colour diluted with rectified spirit of wine, being united with oil of tartar, becomes green. Mem. Acad. Par. 1707.

Boccone is of opinion, that in many plants the colour of the *flowers* is wholly owing to the colour of the juices of the root. This he instances in the greater celandine, whose roots and *flowers* are of the same yellow colour. The barberry in like manner, he observes, has both its roots and *flowers* yellow. The dentillaria has its roots and *flowers* both of a pale red, and the scarlet indica Alcibel, and many other plants, he says, are instances of this. The reason that he assigns for this is, that the more fixed parts wherein this colour consists, preserve the same tincture, without being at all altered by so long a circulation as that from the root to the *flowers*; and he adds another very remarkable observation, which is, that in all these plants and trees, whose roots and *flowers* are of the same colour, the juices are more fixed; and therefore, that these are more fit for dying than any other coloured woods or plants. Vide Boccone, Mus. de Plant.

Dr. Lewis, in his notes on Neumann's Chemistry, has many curious observations on the colours of *flowers*. These are few of them which are constant and invariable, either as to one species of plants, or to the same species in different climates of parts, seasons, years, &c. are very particular. Many *flowers* are their colouring matter, and especially if they are dried in a shady and not warm place. The colours of some people by keeping even in the closest bottles; the same acidity they are dried, and the more perfectly they are secured from air, so much the longer do they retain their beauty. The colouring matter of most extracted and applied to other bodies in the more permanent.

The colour of many blue *flowers* is extracted by infusion in water; but from others, water requires only a purplish hue. Of those which have been tinged, not a few gives a blue colour to spirit of wine; some give no colour, and some give a reddish colour. The expressed juice of these *flowers* is generally blue. The blue juices and infusions are rendered red by all acids; and the most florid red is given to them by mineral acids. The *flowers* also, by maceration, impart a red colour to aqueous liquors. Alkalies fixed and volatile, and lime-water, change these blue colours to green. And those infusions or juices which have nothing of the colour of the *flowers*, follow the same changes from the addition of acid and alkaline liquors. Even when the *flowers* have been kept till their colours

are

are loſt, their infuſions acquire a red colour from acids, and a green colour from alkalies, but in a leſs degree than when the *flowers* were freſh. The red colour produced by acids is fcarce more durable than the original blue, applied upon other bodies, and expoſed to air, it gradually degenerates into a faint purple, and at laſt diſappears, without leaving a ſtain behind. The green produced by alkalies changes to a yellow, which does not fade ſo ſoon. The green made by lime water is more permanent and beautiful. Green lakes, prepared from blue *flowers* by means of lime-water, have been uſed by painters. The *flowers* of cyanus have been much commended for affording elegant and blue pigments. But Dr Lewis has not been able to extract from them any blue colour. They retain their colour, when haſtily dried longer than other blue *flowers*, but do not communicate their original colour to any menſtruum.

Red *flowers* readily communicate their colour to water; and thoſe of a full red colour give to a rectified ſpirit alſo a deep red tincture, brighter, though ſomewhat paler, than the watery infuſion. But the light red *flowers*, and thoſe which are purpliſh, impart little colour to pure ſpirit. The colours of infuſions of theſe *flowers* are ſuppoſed to be heightened by acids, and to be rendered green by alkalies. But this is not univerſal. For amongſt thoſe examined by Dr. Lewis, the roſe colours and purpliſh red were changed by acids nearly as blue *flowers* are; but the full deep reds were not. The deep infuſion of red poppies was turned by alkalies not to a green, but to a duſky purple.

Yellow *flowers* communicate to water and to ſpirit of wine durable yellow colours, not alterable but in degree by acids or by alkalies; the former only rendering them paler; and the latter, as alſo alum, rendering them deeper. Wool, or ſilk, impregnated with a ſolution of alum or tartar, receives, on being boiled with the watery infuſion or decoction, a durable yellow dye. A durable yellow lake is prepared by precipitating with alum an infuſion of yellow *flowers* made in an alkaline ley. In ſome of the orange-coloured *flowers* the yellow matter ſeems to be of the ſame kind as that of the pure yellow *flowers*; but the red matter ſeems to be different from that of the pure red *flowers*. The yellow matter is extracted from theſe *flowers* by water; and the remaining red matter is extracted by ſpirit of wine, or by a weak ſolution of fixed alkali in water. Such are the taſtefree coloured *flowers* of *carthamus*. Theſe *flowers*, after the yellow matter has been extracted by water, are ſaid to give a red tincture to ley, from which a deep red fecula ſubſides, called *ſafflower*, *Spaniſh red*, and *Carthamine*. This pigment gives a beautiful red colour to ſpirit of wine, but none to water. The yellow farina or fine duſt, reſiding on the tips of the ſtamina of *flowers*, gives a fine bright yellow colour to ſpirit of wine, and a paler yellow colour to water. The colours of both the watery and ſpirituous tinctures were heightened by alkalies, rendered red by acids, and again reſtored to a yellow by adding an alkali. This is the only known inſtance of the yellow colour of a vegetable being rendered red by acids. White *flowers*, or their expreſſed juices, impart a green colour to alkaline leys, but have not been obſerved by Dr. Lewis to give a red colour to acids. The white *flowers* of the common wild *anemones* give a deep yellow or orange colour to water, which is affected by acids, by alkalies, and by alum, as the infuſions of yellow *flowers* are. The white *flowers* of *anemone nemoroſa* give a beautiful yellow colour to water acidulated with ſpirit of nitre. See Neumann's Chem. by Dr. Lewis, p. 430-432.

FLOWERS, in *Gardening*, are diſtinguiſhed into *early*, or *ſpring flowers*, which flouriſh in the months of March, April, and May. Of this claſs are the anemonies, daffodils, hyacinths, tulips, jonquils, cowſlips, primroſes, &c. *Summer flowers*, which open in June, July, and Auguſt, as pinks, gilly-flowers, lilies, ſtocks, campanulas, poppies, ſun-flowers, &c. *Autumnal*, or *late flowers*, decore thoſe of September and October; as the aconite, Chriſtmas roſes and roſes, aſters, flower-gentle, &c. Of theſe *flowers*, thoſe which inhabit all the year, we mean in the ſeeds, or root or bulb, are called *perennials*. And thoſe which are to be planted or ſowed afreſh every year, according to the ſeaſon, are called *annuals*.

FLOWERS, preſerving of. The method of preſerving *flowers* in their beauty through the whole year has been diligently ſought after by many people. Some have attempted it, by *gathering* them when dry, and not too much opened, and burying them in dry ſand; but this, though it preſerves their figure well, yet takes off from the liveſneſs of their colour.

The primroſe and cowſlip kind are very eminent inſtances of the change of colours in the *flowers* of dried ſpecimens; for thoſe of this claſs of plants eaſily dry in their natural ſhape, but they not only loſe their yellow, which might be expected naturally enough, but they acquire a fine deep green, much ſuperior to that of the leaves in their moſt perfect ſtate. The *flowers* of all the violet kind loſe their noble blue, and become of a dead white, ſo that in dried ſpecimens there is no difference between the blue flowered violet and the white flowered kinds.

Muntingius gives a method, which he ſays is preferable to all others; this is as follows: gather roſes or other *flowers* when they are not yet thoroughly open. In the middle of a dry day; put them into a good earthen veſſel, glazed within; fill the veſſel up to the top with them; and when full, ſprinkle them over with ſome good French wine, with a little ſalt in it; then ſet them by in a cellar, tying the mouth of the pot cloſe down. After this, they may be taken out at pleaſure, and on ſcenting them in the ſun, or within the reach of the fire, they will open as if on the tree, and not only the colour, but the ſmell will be preſerved.

Sir Robert Southwell has communicated to the world a method of drying plants, by which all *flowers* are preſerved in their natural ſhape, and many in their proper colours. To this purpoſe two ſheets of iron are to be prepared of the ſize of a large half ſheet of paper, or larger for particular occaſions; theſe plates muſt be made ſo thick as not to have any power of bending, and there muſt be a hole made near every corner for the receiving a ſcrew to faſten them cloſe together.

When theſe plates are prepared, lay in readineſs ſeveral ſheets of paper, and then gather the plants with their *flowers*, when they are quite perfect: let this always be done in the middle of a dry day, and then lay the plant and its *flower* on one of the ſheets of paper doubled in half, ſpreading out all the leaves and petals as nicely as can be. If the ſtalk be thick, it muſt be pared or cut in half ſo that it may lie flat; and if it be woody, it muſt be peeled, and only the bark left; then the plant is thus expanded, lay round about it ſome looſe leaves and petals of the *flower*, which may ſerve to complete any part that may prove deficient; when all is thus prepared, lay ſeveral ſheets of paper over the plant, and as many under it; then put the whole into the iron plates, laying the papers ſmoothly on one, and laying the other evenly over them; then ſcrew them cloſe, and put them into an oven after the bread is drawn, and let them lie there two hours; after this make a mixture of equal parts of aquafortis and common brandy; ſhake theſe well together; and when the *flowers* are taken out of the preſſure of the plates, rub them lightly over with a camel's hair pencil dipped in this liquor; then lay them upon freſh brown paper, and covering them with ſome other ſheets, preſs them between this and other papers with a handkerchief, till the wet of theſe liquors is drawn wholly away. When the plant is thus fat prepared, take the quantity of a nutmeg of gum dragon, put this into a pint of fair water cold, and let it ſtand four and twenty hours; it will in this time be wholly diſſolved; then dip a fine hair pencil in this liquor, and with it daub over the backſides of the leaves, and lay them carefully down on a freſh ſheet of white paper lately expanded, and preſs them with ſome more papers over theſe. When the gum water is uſed, let the preſſure and papers be removed, and the whole work is finiſhed. The leaves retain their verdure in this caſe, and the *flowers* always keep their natural colours. Some care muſt be taken, that the heat of the oven be not too great. When the *flowers* are thick and fleſhy, ſome art may be uſed to pare off their backs, and diſpoſe the petals in a fine order; and after this, if any of them are wanting, their places may be ſupplied with ſome of the ſuperfluous dry ones put on for this purpoſe; and if any one of them be loſt indeed, it will be prudent to take them away, and lay down others in their ſtead: the leaves may be alſo diſpoſed and faſtened in the ſame manner. Another way of keeping both *flowers* and fruit the whole year without ſpoiling, is deſcribed by the ſame author in the following manner: take fair-peters, one pound; bole-armoniac, two pounds; clean common ſand, three pounds; mix all well together, then gather fruit of any kind, that is not full ripe, with the ſtalk to them; put theſe in one by one into a wide-mouthed glaſs, laying them in good order; tie over the top with a bladder, and carry the glaſs into a dry cellar, and ſet the whole upon a bed of this prepared matter of four inches thick in a box; fill up the remainder of the box with the ſame preparation, and let it be two inches thick over the top of the glaſs, and round all its ſides. *Flowers* are to be preſerved in the ſame ſort of glaſſes in the ſame manner, and they may be taken up, after a whole year, as plump and as fair as when buried.

FLOWERS, in *Aſtronomy*. We find ſpots in great number at the firſt appearance of the ſun's diſk, being ſeparated by the

the master of the feast, and brought in before the second course; or, as some are of opinion, at the beginning of the entertainment. They not only adorned their heads, necks, and breasts, with *flowers*, but often bellewed the beds whereon they lay, and all parts of the room with them. But the head was chiefly regarded. Potter Archæol. Græc. tom. ii. p. 383. See GARLAND.

Flowers were likewise used in the bedecking of tombs. Potter Archæol. Græc. lib. iv. cap. 7. tom. ii. p. 232, seq. See BURIAL.

FLOWER, in *Architecture*, according to Vitruvius, is a representation of some imaginary *flower*, by way of crowning, or finishing, on the top of a dome, &c. See *Tab. Architecture, fig.* 12.

In lieu of this the moderns commonly use a vase, ball, or the like.

FLOWER-DE-LUCE. FLEUR-DE-LIS, in *Heraldry*, is a bearing anciently of great dignity; being reputed the noblest of all *flowers*; and as such having been in all ages the charge of the royal escutcheon of the kings of France; though time has made the bearing thereof more vulgar. In some coats it is borne single; in others triple; in others it is semee, seeded all over the escutcheon.

FLOWER *of the capital* is an ornament of sculpture, in form of a rose, in the middle of the sweep of the Corinthian abacus.

In that of the Composite, it is not a *rose*, not any real, but an imaginary kind of *flower*.

FLOWERS, in *Chemistry*, are the finest and most subtile parts of dry bodies, raised by fire, into the vessel's head, and studs; and adhering to them, in form of a fine powder, or dust. Such are the *flowers* of sulphur, benjamin, &c.

FLOWERS *of antimony*. See ANTIMONY.

FLOWERS *argentine*, of *regulus of antimony*, are made by putting the regulus into an unvarnished earthen pot, placed in a furnace, so that its bottom may be red-hot, while its upper part shall be much colder. The pot is to be covered with a lid, without luting it, and heat is to be applied for an hour or more. When the pot is cold, its internal surface, and the remaining part of the regulus are found covered with white *flowers*, in form of beautiful, transparent, and shining needles, which are to be gathered with a feather. After this, a second sublimation may be commenced, and managed in the same manner; and the whole regulus may be changed into *flowers*. These *flowers* appear to be nothing else than the earth of regulus of antimony deprived of almost all its phlogiston. They are neither emetic nor purgative; they are soluble in aqua regis.

FLOWERS *of arsenic, white*, are made, as all other *flowers* are, by subliming ARSENIC; from which they do not differ in their nature and properties.

FLOWERS *of benjamin*, or *benzoin*, are made by putting a quantity of this resin into a varnished earthen pan, and covering it with another inverted pan of stone-ware; and let the edges of these pans be made to fit well to each other, and to be well luted together with paper dipped in paste. Put the earthen pan containing the benzoin on a gentle fire, and with that the sublimation is performed; when the vessels are cool and unluted, the *flowers* are to be swept off with a feather. For the properties and medicinal uses of these *flowers*, see BENZOIN.

FLOWERS *of bismuth*. See BISMUTH.

FLOWERS *of cobalt*. See COBALT.

FLOWERS *of copper* have been prepared by subliming sal ammoniac with the caput mortuum of blue vitriol. See COPPER.

FLOWERS, *martial*. See FLORES *martiales*.

FLOWERS *of sal ammoniac* are nothing more than sal ammoniac sublimed; and the sublimation is facilitated by generally mixing with it an equal part of decrepitated common salt. See *Sal* ARMONIAC.

FLOWERS *of sulphur*, or *brimstone*, are the vapours of melted brimstone conveyed from an iron pot (in which it is kept boiling) through a proper flue, into a close room or oven, where this vapour condenses into *flowers*. See SULPHUR.

FLOWER *of wheat, rye*, and other *pulse*. See FARINA and FLOUR.

FLOWERS *of zinc*. See CADMIA and ZINC.

FLOWERS, in the *Animal Oeconomy*, denote women's monthly purgations, or MEURES.

Nicod derives the word in this sense from *fluere*, q. d. *fluere*. Others will have the name occasioned hence, that women do not conceive till they have had their *flowers*; so that these are a sort of forerunners of their fruit.

FLOWERS, in *Rhetoric*, are FIGURES or ornaments of discourse, by the Latins called *floscula*.

FLOWER-*fence, Barbadoes*. See BARBADOES *flower-fence*.

FLOWER-*fence, bastard*. See ADENANTHERA.

FLOWER *of Bristol*. See CAMPION.

FLOWER-*de luce*, in *Botany*. See IRIS.

FLOWER, *starred*, or *star of*. See STARRED *flower*.

FLOWER, *wood*. See ANEMONE.

FLOWER, *fleur d'alisier*. See ALISIER.

FLOWER, *garden*. See ANEMONE, LAVENDER.

FLOWER, *fair maiden*. See ANEMONE.

FLOWER, *fig*. See CHELIDONIUM.

FLOWER, *fulton*. See BUTTON, and CHELIDONIUM.

FLOWER, *sun*. See SUN-*flower*.

FLOWER, *trumpet*. See TRUMPET-*flower*.

FLOWER, *wind*. See ANEMONE.

FLOWER *of Jerusalem*, a name given by the people employed in finding the OSTEOCOLLA to a sort of white marley matter, which they find just on the surface of the ground in the places where the osteocolla is found underneath. It seems very nearly allied to the nature of the osteocolla itself, and usually lies upon it. It is of a blackish matter, resembling earth or mould, and the osteocolla itself is formed upon, and which fills up those hollows we find in most of the pieces, while the whole is in the ground. This rotten vegetable matter has much the resemblance of the roots or branches of trees, and is called by the common people the root of the osteocolla or hammoniac rock. Phil. Trans. N° 30.

FLOWER-*pot worm*, in *Natural History*, a peculiar species of fly-worm, which makes its habitation only in the bulbous roots of *flowers*. The roots of the narcissus at the time they are taken up out of the earth toward the end of autumn, very frequently are found to contain each a single worm, which eats and destroys them. Sometimes one root is found to contain two of them; but this is but rarely the case. The roots which have them may easily be known, by having each a round hole in some part, at which the destroyer has entered while it was small, and which probably serves it now in its large state for respiration of the freer air. The interior part of these bulbs is always found rotted and destroyed, and the worm is found in these, lying in a brown sort of dirt made by its own liquid excrements, mixed among the fragments of the coats of the root which it has destroyed. Reaumur's Hist. Insect. vol. iv. p. 499.

These worms undergo all their changes in a shell made of their own skin, which is of the same egg-fashioned shape with that of the blue flesh-fly, but considerably larger, and of a greyish colour. But this is not all its difference from those shells; for on its anterior and superior part it has two horns of the same kind with the four of the shells of the rat-tailed worms; and seeming to serve to the same purposes, and to convey the air necessary for the life of the creature, into its receiver; the old stigmata, which served the creature in its worm-state, being now obliterated, and something necessarily wanted in their place. After having undergone all the necessary changes, the shells are burst open, in the month of April, and let out the fly they contained.

This has also so much the appearance of an humble-bee, that at first sight it is scarce to be distinguished from it. It is covered with black, yellow, and reddish hairs, as the smaller kinds of the common humble-bees are; but its antennæ, which are of the butterflies fashion, prove plain enough, that it is really no bee, even before one can determine with certainty that it has only two wings.

FLOWERAGE, a collection of flowers of several kinds set together in husks, and hung up with strings.

FLOWERED, in the *Manufactures*. A stuff, or cloth, is said to be *flowered*, *flourished*, *sprigged*, or *figured*, when there are representations of *flowers*, either natural, or imaginary, wrought thereon.

There are stuffs *flowered* of almost all kinds of matter: *flowers* of gold, silver, silk, wool, thread, cotton, &c. Stuffs and cloths are usually denominated from the ground, wherein the *flowers* are raised.

Thus, there are *flowered* velvets, taffeties, damasks, fattins, mohairs, dimities, &c.

Those *flowered* with gold and silver are more usually called BROCADES.

The flowers are usually wrought at the same time with the cloth, or ground. The threads of the warp are raised and lowered by means of pin-threads passed through them in mounting the loom; and the manufacturer, throwing his warp, or matter of the flowers, whether gold, silver, silk, or the like, between the threads thus raised, forms the FLOWERS.

It is very curious to see them mount a loom; or, as they call it, *tend a dessein*, to be represented on a stuff; but it is next to impossible to describe it; yet we have endeavoured to give some idea thereof under DESIGN.

FLOWERING *of bulbous plants*. These plants will grow and *flower* in water alone, without any earth, and make a very elegant appearance. We daily see this practised in single roots, but there is a method of doing it with several together, as follows: take a common small garden-

pot,

pot, stop the hole at the bottom with a cork, and lute in the cork with putty that no water can get through; then fit a board to the top of the pot, and bore six or seven holes in it, at equal distances, to place the bulbs in, and as many smaller holes near them to receive the sticks, which will serve to tie up the *flowers*. Then fill up the pot with water to the board, and place tulips, jonquils, narcissuses and the like plants in the pot upon the holes, so that the bottom of the roots may touch the water; thus will they all *flower* early in the season, and be much more beautiful than any pot of gathered *flowers*, and will last many weeks in their full perfection. After the season of *flowering* is over, the roots will gradually shrink through the holes of the board, and get loose into the water, but instead of becoming spoiled there, they will soon increase in size, so as not to be capable of coming back, and will produce several off-sets. It is natural to try from this the consequence of keeping the roots under water during the whole time of their blowing, and in this manner they have been found to succeed very well, and *flower* even stronger and more beautifully than when in the ground. They may thus also, with proper care in the degree of heat in the room, be kept *flowering* from before Christmas, till March or April. It is not easy in this last manner to manage the keeping of the boards under water, for which reason it is better to procure some sheet lead of about four pounds to the foot, and cut this to the size of the mouth of the pot; in this there should be bored holes for the bulbs, and other holes for the sticks; and in order to keep the sticks quite firm, it is proper to have another plate of lead shaped to the bottom of the pot, with holes in it, answering those in the upper plate made for the sticks. The sticks by this means will be kept always perfectly steady, and the roots being kept under water by the upper plate of lead, will *flower* in the most vigorous and beautiful manner imaginable.

Notches in the side of each lead, will give easy passage to the water, that if there should be any foulness or sediment in it, on shaking it a little, it may all run through, and fresh water be put in its place; but this shifting the water need not be done more than once or twice in a winter, as there may be occasion from the foulness; and when this is done, the sides of the vessel should be cleaned with a painter's brush and rinsed out again, and the bulbs themselves washed, by pouring water on them at a little distance: and if any dull or foul matter be at any time observed swimming on the surface, the method is to fill up the vessel, and let it run over: this will carry off that light foulness, and the water may afterwards be poured away to the proper standard.

It may be more agreeable to some to use glass jars, in this last method with the lead, instead of earthen pots. The bulbs succeed full as well in these; and there is this advantage, that the progress of the roots is seen all the while, and they are managed better as to the supply of water.

By repeated experiments in this way on dried bulbs, and on those taken fresh out of the ground, the former have been found to succeed the best; for those taken fresh out of the ground being full of moisture, will not so soon upon changing their element be nourished fully by a new one; and the fibres which they had struck in the ground always rot when put into the water, and new ones must be formed in their places, so that it requires more time for them to come to *flowering*. The bulbs themselves will not rot in this manner, but they will never be so strong as those which were put into the water dry, which gradually fill themselves with moisture from it, and regularly plump up. The best method of managing the whole process is this: place the bulbs at first only on the surface of the water; for those they will strike out their fibres most strongly. When they have stood thus for weeks, pour in the water so high as to cover them entirely, and keep them at this standard till they have done *flowering*.

Sometimes the roots will become mouldy in several parts while they stand above the water, and the cleaning them of it is to no purpose; for it will eat and spread the farther, and frequently eat through two or three of their coats. In this case, they must be immediately covered with water, and the mould will be stopped, and they will become sound, and flower as well as those which never had any such disemperature. If the roots are suffered to remain in water all the year, they will not decay, but will flower again at their proper season, and that as vigorously as those which are taken out and dried. The old fibres of those roots never rot till they are ready to push out new ones. It is found by experience, that the hyacinth, and many other plants, grow to greater perfection thus in water, than when in the ground. There is a peculiar species of hyacinth, called Keyser's jewel; this never, or however very rarely, produces seed-vessels in the common way of *flowering* in the ground, but it will often produce some pods when blown in water.

Mr. Miller has intimated, in the Philosophical Transactions, that bulbs set in glasses grow weaker, and should be renewed with fresh ones every other year; but it is found that when they are managed in this manner, and kept under water, at the time of taking them up, they are as large, and some of them larger and stronger than when planted; and if these be dried at a proper season, they will flower year after year as well as at first.

The smaller sorts may also be raised in this manner, by the help of wool to support them.

No plant transplanted out of earth into water will thrive kindly; but any plant, whether raised from the root or seed in water, may be transplanted to the earth, and will succeed very well. It may be possible, therefore, from this method of raising plants in water, to come at a better way than is usually practised of raising some roots in the earth which are subject to rot there; such as anemonies, ranunculuses, and hyacinths. A bulb dropped by chance upon the ground will strike out both stronger and more numerous fibres, than those which are planted in the usual way on the ground. On this principle it may be proper to take out the earth of the bed where the bulbs are to stand at the time of planting them, to such a depth as they are to be placed under it, when set for *flowering*. The bulbs are then to be set in their places on the surface of this low ground and to stand there till they have shot out their fibres and their heads, when the earth is to be added over them by degrees, till they are covered as high above the bed as they are in the usual way of planting them; thus they would be preserved from the danger of rotting, and their fibres would be much stronger, and consequently they would draw more nourishment, and flower better than in the common way.

At the time of planting the bulbs, they must be carefully cleaned from any foulness at the bottom, by scraping them clean with the point of a knife, till the sound part of the bulb appears; clean them likewise from any loose skins, and even take off their brown skin, till they appear white; otherwise this brown skin will tinge the water, and the growth will not succeed so well.

There is yet another way of causing flowers to blow early in pots of earth in this manner. Dissolve crude sal ammoniac in water, in such proportion, as that a piece of the bignefs of a walnut may be dissolved in every quart; then prepare some pots of a proper size filled with good garden mould. Sow the annual flowers, and set the roots of the perennial ones, such as tulips, &c. in these pots at Michaelmas; continue the enfuing season to water them with the solution of the salt, and keep them in a warm room; by this means they will be in full flower about Christmas, and will continue through January and February.

FLOWING, or FLOWS, *Sea-Language*, denote the positions of the sheets, or lower corners of the principal sails, when they are loosened to the wind, so as to receive it into their cavities in a direction more usually perpendicular than when they are close-hawled, but more obliquely than when the vessel is sailing before the wind. This position of the sheets takes place when the wind cross the line of her course nearly at right angles.

FLOX, in the *Colour Trade*, a very well cleaned wool used to absorb the colours of cochineal, &c. It is prepared in this manner: infuse a pound of the finest shearings of woollen cloth in cold water for one day; then take them up, and press them well together, to wash off the unctuosity the wool naturally has. This is the simple *flox*, which when impregnated with a solution of alum, is called alumed *flox*. This is done in the following manner: take four ounces of roche-alum, and two ounces of crude tartar, both in fine powder; put them into an earthen vessel with three quarts of water, let it over the fire, and when it begins to boil, then put in the *flox*; let the liquor now boil half an hour over a gentle fire, then take it off, and when all is perfectly cooled, wash the *flox* with fair water, letting them stand in it two hours, then press them in the hand, and let them dry.

FLUDER, or *Sea-Flounder*, in *Ornithology*, the name of a water-fowl of the columbus or diver-kind, described by Gesner, and some other authors, under the name of the columbus maximus, or largest diver. It is nearly of the size of a goose, and moves but very slowly on the water, and much worse either on land, or in the air, being but little able either to walk or fly. Its beak is long, and its legs very short; it makes a very shrill noise, and is remarkable for diving to vast depths. Its feet are webbed, its back is of a greyish colour, and its belly white. It seems much to approach to the northern columbus, called the lumme, and perhaps differs only in colour, which may be an accidental variety, as it is common in birds. Ray's Ornithol. p. 260.

FLUELLIN, *Elatine*, in *Botany*. See ELATINE.

FLUENT, or *flowing quantity*, in the *Doctrine of Fluxions*, that quantity (whether line, surface, solid, &c.) which is continually increasing, or decreasing.

Those *fluents*, which are generated in the same time, or in equal times, or which begin together and end together, are called contemporary *fluents* and their *fluxions* are called contemporate *fluxions*; and if two or more of these contemporary *fluents* are always equal, or in any invariable ratio to each other, their contemporary fluxions will likewise be equal, or in the same proportion, and *vice versâ*. See FLUXION.

Mr. Maclaurin, in his Treatise of Fluxions, has made several enquiries into *fluents*, reducible to the rectification of the ellipsis and hyperbola. M. D'Alembert has pursued the same subject, and carried it farther, in Mem. de l'Acad. de Berlin, ann. 1746. p. 266.

FLUIDITY, in *Physics*, that state or affection of bodies which denominates or renders them *fluid*.

Fluidity stands in direct opposition to *firmness*, or *solidity*.

Fluidity is distinguished *from Liquidity* or *humidity*, in the idea of the first is absolute, and the property contained in the thing itself; whereas that of the latter is relative, and implies wetting, or adhering; i. e. something that gives to the fingers of women, or mothers, and which would have no existence but for our senses.

Thus melted metals, air, or ether, and even smoke, and flame itself, are *fluid* bodies, but not liquid ones; their parts being actually dry, and not bearing any sense of moisture.

The nature and causes of *fluidity* have been variously assigned.

The Gassendists, and ancient Corpuscularians, require only three conditions as necessary thereto; viz. a smallness and smoothness of the particles of the body; vacancies interspersed between them; and a spherical figure. Thus the Epicurean poet, Lucretius:

Hæc eadem docent ea omnibus atque rotundis
Esse magis, fluidoque corpore liquida constant.

The Cartesians, and after them Dr. Hook, Mr. Boyle, &c. beside the circumstances above mentioned, require a various, perpetual, intestine motion of the particles of the bodies, as that which principally contributes to *fluidity*.

Fluidity then, according to these philosophers, consists in this, that the parts of the body, being very fine, and small, are so disposed by motion, or figure, as that they can easily slide over one another's surfaces all manner of ways; and that they be in constant, various, separate agitation to and fro; and that they only touch one another in some few parts of their surfaces. Mr. Boyle, in his *history of fluidity*, mentions three conditions principally required to *fluidity*, viz.

1. The minuteness of parts: thus, in effect, we find that fire, by dividing metals into fine, small parts, renders them fluid; and that acid menstruums dissolve and render them fluid after the like manner; and that fire turns the hard body of common salt almost wholly into a liquor, by distillation: not but that the figure of the particles may have a considerable share in *fluidity*.

Thus mercury, whose parts are doubtless much grosser than those of oil and water, is yet more fluid than either of them: and thus oil, by the action of fire, may be converted into a constituent substance like butter.

2. A number of vacancies interspersed between the corpuscles, to give room for the several particles to move among themselves.

3. A motion and agitation of the corpuscles; either from some principle of mobility within themselves, or from some extraneous agent, penetrating and entering the pores, moving variously among them, and communicating to them a part of its motion.

That this last is the qualification chiefly required in *fluidity*, he argues from divers observations and experiments. Thus, a little dry powder of alabaster, or plaister of Paris, finely sifted, being put in a vessel over the fire, soon begins to boil like water; exhibiting all the motions and phænomena of a boiling liquor. It will tumble variously in great waves like that; will bear stirring with a stick or ladle like that, without resisting; nay, if strongly stirred near the side of the vessel, its waves will apparently dash against them: yet it is all the while a dry, parched powder.

The like is observed in sand; a dish of which being fed on a drum-head, briskly beaten by the sticks, or on the upper stone of a mill, it in all respects emulates the properties of a fluid body. A heavy body, e. gr. will immediately sink in it to the bottom, and a light one emerge to the top. Each grain of sand has a constant vibratory and dancing motion; and if a hole be made in the side of the dish, the sand will spin out like water.

That the parts of fluids are in continual motion, the Cartesians bring divers co[illegible] The transmutation of fo[illegible] water, and vice versâ; the [illegible] body in those two cases [illegible] being fixed and at rest [illegible] whereas in the other, [illegible] not to the highest imp[illegible]

2. The effects of fluids [illegible] motion: such are the [illegible] pores of bodies; the [illegible] the schisms of cor[illegible] intervention of some [illegible] air, or water.

As the same gentlemen [illegible] causes of *fluidity*, [illegible] and water, though [illegible] from the nether or [illegible]

Boerhaave pleads [illegible] fire's being the first *mover*, and the cause of *fluidity* in other bodies, as air, water, &c. Without [illegible] he shews that the atmosphere itself would fix into one solid mass. See FIRE and HEAT.

Sir I. Newton sets aside this theory of the cause of *fluidity*, and substitutes a new one, the great principle of attraction. The corpuscular system, with all the improvements of Descartes, and Mr. Boyle, did not sufficiently account for the primary condition, requisite to constitute a *fluid*, viz. the various intestine motion and agitation of its particles. But this motion is naturally enough accounted for, by supposing it a primary law of nature, that as all the particles of matter attract each other when within a certain distance; so at all greater distances they fly from, and avoid one another. For then, though their common gravity, together with the pressure of other bodies upon them, may keep them together in a mass, yet their continual endeavour to avoid one another singly, and the repetitious impulses of heat, and light, or other external causes, may make the particles of fluids continually move round about one another, and so produce this quality.

There is a difficulty, indeed, in accounting, why the particles of fluids always keep at such a distance from one another, as not to come within the sphere of one another's attraction. The fabric and constitution of that fluid body, water, is amazing; that a body so very rare, and which has a vast over proportion of pores, or interspersed vacuity, in solid matter, should yet be perfectly incompressible by the greatest force, as philosophers very generally and for a long time have imagined, (*See* COMPRESSION) and yet this fluid is easily reducible into that firm, transparent, friable body, which we call ice, by being only exposed to a certain degree of cold.

One would think, that though the particles of water cannot come near enough to attract each other, yet the intervening frigorific matter doth, by being mingled per minima, strongly attract them, and is itself likewise strongly attracted by them, and so wedges or fixes all the main into a firm solid body; which solid body loses its fluidity again, when by heat the vinculum is solved, and the frigorific particles are disjoined from those of the water, and are forced to fly out of it. And thus may the fumes of lead perhaps fix quicksilver.

When a firm solid body, such as metal, is by heat reduced into a fluid, the particles of fire disjoin and separate its constituent parts, which their mutual attraction caused before to cohere, and keep them at such a distance from one another, as that they are out of the sphere of each other's attraction, as long as that violent motion lasts; and when by their lightness and activity they are flown off, unless they be renewed by a continual supply, the component particles of the metal finally come near enough again to feel one another's attractions.

As, therefore, the cause of cohesion of the parts of solid bodies appears to be their mutual attraction, so the chief cause of *fluidity* seems to be a contrary motion, impressed on the particles of fluids; by which they avoid and fly one another, as soon as they come at, and as long as they keep at such a distance from each other.

It is observed also in all fluids, that the direction of their pressure against the vessels which contain them is in lines, perpendicular to the sides of such vessel; which property, being the necessary result of the particles of any fluid's being spherical, shews that the parts of all fluids are to, or of a figure very nearly approaching thereto.

FLUIDS are bodies, whole particles are but weakly connected, their mutual cohesion being in a great measure prevented by some external cause.

In this sense *fluids* stand opposed to *solids*.

Sir I. Newton defines a *fluid* body, to be that whose parts yield to the smallest force impressed, and by yielding are easily moved among each other.

That

That the particles whereof fluids consist, are of the same nature, and have the same properties, with the particles of solids, is evident, from the conversion of liquids and solids into each other, e. gr. of water into ice, of metals into fluors, &c. Nor can it be reasonable doubted, that the component parts of all bodies are the same, viz. hard, solid, impenetrable, moveable corpuscles.

We observe they have, with Dr. Clarke, that if the parts of a body either do not touch each other, or easily slide over one another, and are of such a magnitude, as that they may be easily agitated by heat, and the heat be sufficiently great to agitate them, though it may perhaps be less than suffices to prevent water from freezing; or, even, though the parts be not actually moved, yet, if they be small, smooth, slippery, and of such a figure and magnitude as supposes them to move, and give way, that body is *fluid*.

And yet the particles of such *fluid* bodies do, in some measure, cohere; as is evident hence, that mercury, when well purged of air, will be sustained in the barometer, to the height of 60 or 70 inches; that water will ascend in capillary tubes even in vacuo; and that the drops of liquor in vacuo run into a spherical form; as adhering by some mutual cohesion like that between polished marble planes. Add, that these *fluid* bodies, if they consist of particles that are easily entangled within each other, as oil; or if they be capable of being thickened by cold, and joined by the interposition of little cords or wedges, as water; they are easily rendered hard: but if their particles be such as can neither be entangled, as air, nor thickened by cold, as quicksilver; then they never grow hard any length.

FLUIDS are called either *natural*, as water, and mercury: or *animal*, as blood, milk, bile, lymph, urine, &c. or *factitious*, as wines, spirits, oils, &c. See each under its proper article.

The doctrine and laws of *fluids* are of the greatest extent in philosophy. The pressure and gravitation of bodies in *fluids*, and the action of the *fluid* immerged in them, make the subject of HYDROSTATICS.

FLUIDS, *hydrostatical laws of*. I. The upper parts of all *fluids*, as water, &c. do press upon the lower; or, as some philosophers state it, all *fluids* do gravitate in *proprio loco*.

The contrary of this was a principle in the school-philosophy; and two facts have been commonly urged in support of it. A bucket full of water is lighter in the water than out of it, nor does it weigh more when full in the water, than when empty out of it: therefore, it has been concluded, that the water in the bucket, because it is within water, its own element, does not gravitate: and divers who descend to considerable depths, it has been said, feel no sensible pressure under water; though at the depth of thirty-two feet, the additional pressure they sustain is not less than twenty thousand avoirdupois pounds: for, supposing the surface of the body to contain only ten square feet, and a cubic foot of water to weigh one thousand avoirdupois ounces, 32×10 feet, or 16×20 feet of water will weigh 16×20000 avoirdupois ounces, or twenty thousand pounds. However, in this case, the uniformity of the pressure, the increased elasticity and resistance of the compressed internal air, and the firm texture of the membranes, &c. may prevent their complaining of any sensible pain; though there have been many instances to the contrary, in which the difference of the pressure has produced very injurious effects. See DIVING.

As to the former fact, it is easily explained by the theory of *specific* GRAVITY. The bucket of water weighs in water, but does not overweigh; because the surrounding parts of water endeavour to descend as well as the bucket, and with equal force, and therefore do not permit it to descend. Thus, according to an observation of Dr. Desaguliers, if two pound weights were hung at the two arms of a balance, no one will say, that neither weighs, because it does not outweigh the other. Desag. Exp. Phil. vol. ii. p. 69.

Besides, it is evident, that, in any *fluid*, the weight of the whole is equal to the weight of all its parts; and if any part be taken from the whole, the weight of the whole will be diminished by the weight of that part; and if any part be added to the whole, the weight of the whole will be increased by the weight of the part which was added; and, therefore, it is reasonable to conclude, that the weight of the whole is composed of the weights of the several parts, and that the parts do, therefore, gravitate in the whole, or in *proprio loco*. Cotes's Hyd. and Pneum. Lectures, p. 7. But the certainty of such pressure is now demonstrated by a thousand experiments: it will be sufficient to instance one or two.

Immerge a tube, open at both ends, and half filled with oil of turpentine, into a vessel of water, the upper end of the tube being stopped with the finger: if now the upper surface of the oil be as low as that of the water, the oil, upon removing the finger, will not run out at the lower end of the tube; nay, and if the tube be thrust a little lower, the water will rise up in it, and bear the oil above it: but if the upper surface of the oil be considerably higher than that of the water, the oil will drop out of the tube. Whence it follows, that the column of oil in one case presses on gravitates less on the plane imagined to pass under its lower surface, than a column of water; and in the other case, more.

Or thus: a phial, with as much shot in it as will make it sink, close shut, being immerged in water, and suspended by a horse-hair to the beam of a balance, with a weight at the other end exactly counterpoising it; upon unstopping the phial, and letting it fill with water, it will presently sink, and bear down the end of the balance, without having any communication with the external air. And if the phial had been first weighed in air, it will be found, that the weight necessary for restoring its equilibrium in water, answer exactly to the additional weight of the phial, when it is again weighed in air with the water in it; so that water weighs in water just as much as in air.

These two experiments abundantly prove the proposition, that the upper parts of *fluids* do really press or gravitate on the lower. See *Specific* GRAVITY.

From this gravity it follows, that the surfaces of stagnant *fluids* are plain, and parallel to the horizon; or rather, that they are segments of a sphere concentrical with the earth, because they all gravitate towards the centre of the EARTH.

For, as the particles are supposed to yield to any force impressed, they will be moved by the action of gravity, till such time as none of them can descend any lower. And in this situation once at rest, the *fluid* must remain at rest, unless put in motion by some foreign cause: inasmuch as none of the particles can now move without ascending, contrary to their natural tendency.

II. If a body be immerged in a *fluid*, either wholly, or in part, its lower surface will be pressed upwards by the water underneath it; and the pressure of *fluids* upwards is equal to the pressure downwards at the same depth.

The truth of this proposition is evident from the experiment above mentioned; where the oil of turpentine was suspended, and made to mount up in the tube, by the pressure of the water upwards on its lower parts. Thus also, if the open end of a narrow-bored tube be stopped into quicksilver, whilst the other end is stopped with the finger, and the tube be filled up, a short column of quicksilver will be suspended in the lower end, which column, when dipped into water deeper than about fourteen times its own length, will be pressed upwards, after the finger is removed from the orifice.

This upward pressure of *fluids* may be evinced by causing a piece of lead, &c. to swim in water; which may be done by immersing it to a proper depth, and keeping the water from getting above it. Let CD, *Tab.* II. *Hydrostatics*, *fig.* 10. be a glass tube open at both ends, and EFG a flat piece of lead half an inch thick, exactly fitted to the lower end of the tube, having its upper surface covered with wet leather, so as to hinder the entrance of the water contained in the outer vessel. Let this leaden plate be held close to the tube, by pulling the string or wire HI, upward at I, with one hand, whilst the tube is held in the other by the upper end C. In this situation, let the tube be immersed in water in the glass-vessel AB, to the depth of six inches below the surface of the water at K; and then, the leaden plate EFG will be plunged to the depth of somewhat more than eleven times its own thickness: holding the tube at that depth, you may let go the wire or thread at I, and the lead will not fall from the tube, but will be kept to it by the upward pressure of the water below it, occasioned by the height of the water at K above the level of the lead. For, as lead is 11.33 times as heavy as its bulk of water, and in this experiment is immersed to a depth somewhat more than 11.33 times its thickness, and no water getting into the tube between it and the lead, the column of water EabG, below the lead, is pressed upward against it by the water KDEGL, all round the tube; which water, being a little more than 11.33 times as high as the lead is thick, is sufficient to balance and support the lead at the depth KE. If a little water be poured into the tube upon the lead, it will increase the weight upon the column of water under the lead, and cause the lead to fall from the tube to the bottom of the glass vessel, where it will lie in the situation bde: or, if the tube be raised a little in the water, the lead will fall by its own weight, which will then be too great for the pressure of the water

round

round the tube on the column of water below it. If the plate were brass inſtead of lead, it ought to be immerſed under water at leaſt eight times its thickneſs, in order to be ſupported by the water; becauſe braſs is about eight times ſpecifically heavier than water. A plate of pure gold would require near twenty times its thickneſs of water: and this led Mr. Boyle to propoſe one of his hydroſtatical paradoxes in theſe words, viz. That a ſolid body, as ponderous as any yet known, though near the top of the water it will ſink by its own weight, yet immerſed in water, at a greater depth than that of twenty times its thickneſs, will not ſink, if its deſcent be not aſſiſted by the weight of the incumbent water. Paradox. 21. Scnica. Boyle's Works, abr. by Shaw, vol ii. p. 311.

As we have now ſeen that the heavieſt body may be made to ſwim in water, the lighteſt wood may be made to lie at the bottom of water or mercury. Thus, let two pieces of wood be planed quite flat, ſo that no water may get between them when they are put together; let one of them, b d, be cemented to the bottom of the veſſel A B, *fig.* 10. and the other be laid flat and cloſe upon it, and held down with a ſtick, whilſt water is poured into the veſſel; then remove the ſtick, and the upper piece of wood will not riſe from the lower one, for as the upper one is preſſed down both by its own weight and the weight of water over it, whilſt the contrary preſſure of the water is kept off by the wood under it, it will lie as ſtill as the heavieſt body; but if it be raiſed at the edge, ſo that the water may get under it, it will immediately be preſſed upwards, and as it is lighter than its bulk of water, it will riſe and float on the ſurface of the water. See Ferguſon's Lectures, 4to. p. 68. and Cotes's Hyd. Lect. 2. See HYDROSTATIC *Ballows*, and ART. xi. in the ſequel.

The law of quantity of this preſſure is this; that a body immerged in a *fluid*, loſes juſt ſo much of the weight it would have in air, as ſo much of the *fluid* as is equal to it in bulk, if weighed in the air, would amount to.

This preſſure of *fluids* on the lower parts of an immerſed body, is farther confirmed, by attending to the reaſon why bodies, ſpecifically lighter than *fluids*, aſcend therein. The effect is owing to this, that there is a greater preſſure or weight on every other part of the plane or ſurface of the *fluid* imagined to paſs under the lower ſurface of the body, than there is on that wherein the emerging body inſiſts. Conſequently, to produce an equilibrium in the *fluid*, the parts immediately under the riſing body, being preſſed by the reſt every way, do continually force it upwards.

In effect, the emerging body is continually preſſed on by two columns of water, one bearing againſt its upper and the other againſt its lower parts: the length of both which columns being to be accounted from the top of the water, that which preſſes on the lower part will be the longer, by the thickneſs of the aſcending body, and conſequently will overbalance it by the weight of as much water as will fill the ſpace that body takes up.

Hence, 1. We are furniſhed with one reaſon, why very minute corpuſcles, either heavier or lighter than the liquor they are mingled with, will be ſuſtained therein a good while, without either emerging to the top, or precipitating to the bottom; the difference between the two columns of the *fluid* being here inconſiderable.

Hence, 2. If a body A be ſpecifically lighter than B, an equal portion of the *fluid* in which it is immerged, it will riſe with a force proportionable to the excels of gravity of B above A: and if A be ſpecifically heavier than B, it gravitates and deſcends with the exceſs only of its weight above that of B.

Hence, 3. We have a ſolution of the phenomenon of two poliſhed marbles or other planes adhering ſo ſtrongly together; becauſe the atmoſphere preſſes or gravitates with its whole weight on the under ſurface and ſides of the lower marble, but cannot do ſo at all on its upper ſurface, which is cloſely contiguous to the upper and ſuſpended marble.

III. The preſſure of the upper parts of a *fluid* on the lower exerts itſelf every way, and every way equally, laterally, horizontally, and obliquely, as well as perpendicularly.

For, as the parts of a *fluid* yield to any impreſſion, and are eaſily moved, it is impoſſible any drop ſhould remain in its place, if, while it is preſſed by the ſuperincumbent *fluid*, it be not equally preſſed on every ſide.

The ſame is confirmed from experiment; for ſeveral tubes of divers forms, ſtrait, curved, angular, &c. being immerged in the ſame fluid, though the apertures, through which the *fluid* enters, be differently poſited to the ſurface or plane, ſome being perpendicular, others parallel, and others variouſly declined; yet will the *fluid* riſe to an equal height in them all. See SYPHON.

Hence, 1. All the particles of *fluids* being thus equally preſſed on all ſides, it is argued, that they muſt be at reſt, and not in continual motion, as has been uſually ſuppoſed.

Hence, 2. alſo, A body, being immerſed in a *fluid*, ſuſtains a lateral preſſure from the *fluid*, which is alſo increaſed as the body is placed deeper towards the ſurface of the *fluid*.

IV. In tubes that have a communication with each other, whatever their magnitude be, whether equal or unequal; and whatever their form, whether ſtrait, angular, or crooked; ſtill, *fluids* riſe in them to the ſame height.

V. If a *fluid* riſe to the ſame altitude in two tubes that communicate with each other, and the tubes in that ſituation is a balance, or equal in weight, ſo will they be to the other.

If the tubes be of equal bores, the columns of the *fluid*, having the ſame baſe and altitude, are equal, and conſequently their gravities are equal, ſo that they preſs and gravitate againſt each other with equal force.

This is demonſtrated from theſe principles. E. gr. Let the baſe of G I, *Tab. II. fig.* 11. be ſuppoſed quadruple the baſe of H K, and let the *fluid* deſcend in the greater tube the ſpace of an inch, as from L to O; it will then riſe in the other the ſpace of four inches, as from M to N. Wherefore the velocity wherewith the *fluid* moves in the tube H K, is to that wherewith it moves in G I, as the baſe of the tube G I, to the baſe of the other, H K. But the altitude of the *fluid* being ſuppoſed the ſame in both tubes, the quantity of the *fluid* in the tube G I will be to that in the other tube H K, as the baſe of the tube G I to the baſe of the other H K. Conſequently, the momentum of the *fluid* in the tube G I is to that in the tube H K, as the product of the baſe of the tube G I into the baſe of the other H K, to the factum of the tube H K into the baſe of the other G I. Wherefore, the products being equal, the momenta muſt be equal.

The ſame is eaſily demonſtrated where one of the tubes is inclined, and the other perpendicular, &c.

Hence in tubes that communicate, the *fluid* will preponderate in that where its altitude is the greateſt.

VI. In communicating tubes, *fluids* of different ſpecific gravities will equiponderate, if their altitudes be in the ratio of their ſpecific gravities.

Hence we have a way of finding the ſpecific gravities of *fluids*, viz. by pouring one *fluid* into one of the communicating tubes, as A B (*fig.* 12.) and another into the other tube C D; and meaſuring the altitudes G B and H D, at which they ſtand when balanced.

For the ſpecific gravity of the *fluids* in A B is to that in D C, as D H to B G. If the *fluids* employed in this experiment be apt to mix, it may be proper to fill the horizontal tube B D with mercury, to prevent the mixture.

Hence, ſince the DENSITIES of *fluids* are as their ſpecific gravities, the denſities will likewiſe be as the altitudes of the *fluids* D H and B G; ſo that we have hence likewiſe a method of determining the denſities of *fluids*.

VII. The bottoms and ſides of veſſels are preſſed in the ſame manner, and by the ſame laws, as the liquids contained in them.

And hence, as action and re-action are equal, the *fluids* themſelves ſuſtain an equal preſſure from the bottoms and ſides. And as the preſſure of *fluids* is equal every way, the bottom and ſides are preſſed as much as the neighbouring parts of the *fluids*; and conſequently this action increaſes in proportion to the height of the *fluid*, and is equal every way at the ſame depth; as depending altogether on the height, and not at all on the quantity of the *fluid*.

VIII. In perpendicular veſſels of equal baſes, the preſſure of *fluids* on the bottoms is in the ratio of their altitudes. This is evident, becauſe, the veſſels being perpendicular, the bottoms are horizontal: conſequently the tendency of *fluids* by the action of gravity will be in lines perpendicular to the bottoms, ſo that they will preſs with all their weight; the bottoms therefore are preſſed in the ratio of the gravities. But the gravities are as the bulks, and the bulks here are as the altitudes; therefore the preſſure on the bottoms are as the altitudes.

IX. In perpendicular veſſels of unequal baſes, the preſſure on the bottoms is in a ratio compounded of the baſes, and altitudes.

From the preceding demonſtration it appears, that the bottoms are preſſed in the ratio of the gravities: and the gravities of *fluids* are as their bulks; and their bulks in a ratio compounded of the baſes and altitudes. Conſequently, &c.

X. If an inclined veſſel A B C D, *fig.* 13. have the ſame baſe and altitude with a perpendicular one, B E F G, the bottoms of each will be equally preſſed.

For, in the inclined veſſel A B C D, the bottom C D is preſſed in the direction B D. But the force of gravity in the direction B D is to the abſolute gravity, as B E to B D.

Conſe-

Consequently the bottom CD is preſſed in the ſame manner, as if it had been preſſed perpendicularly by the *fluid* under the altitude FE. Therefore, the bottoms of the perpendicular and inclined veſſels are equally preſſed.

XI. *Fluids* preſs upon ſubject bodies, according to their perpendicular altitude, and not according to their latitude, or breadth.

Or, in other ſhte it, thus: if a veſſel be taper, or unequally big as to its top and bottom, yet the bottom will be preſſed after the ſame manner as if the veſſel were cylindrical, and the top and bottom equal.

Or thus: the preſſure ſuſtained by the bottom of a veſſel, whatever the figure of the veſſel be, is ever equal to the weight of a column of the *fluid*, whoſe baſe is the bottom itſelf, and its height the vertical diſtance of the upper ſurface of the water from the bottom.

Or, yet more explicitly thus: if there be two tubes or veſſels, having the ſame heights, and baſes, both filled with water; but one of them made to tapering upwards that it ſhall contain but twenty ounces of water; whereas the other, widening upwards, holds two hundred ounces; yet the bottoms of the two tubes ſhall ſuſtain an equal preſſure of water, viz. each of them that of the weight of two hundred ounces.

This is a noble paradox in hydroſtatics, firſt diſcovered by M. Paſchal, and which it is well worth the obſerving and inſiſting on. It is found unexceptionably true from abundant experiments; and it may even be demonſtrated and accounted for on principles of mechanics.

Suppoſe, e. g. the bottom of a veſſel CD (*fig.* 15.) leſs than its top AB; ſince the *fluid* preſſes the bottom CD, which we ſuppoſe horizontal, in a perpendicular direction, EC, more but that part within the cylinder ECDF can preſs upon it, the natural tendency and preſſure of the reſt being taken off by the ſides.

Again, ſuppoſing the bottom CD (*fig* 15.) much bigger than the top FG; or even, for the eaſier demonſtration, ſuppoſe a tube FE fixed in a cylinder ABCD; and ſuppoſe the bottom CD raiſed to I, that the *fluid* may be moved through the interval DI: then will it have riſen through the altitude GI, which is to DI as the baſe CD to that of GF. The velocity therefore of the *fluid* FE is to its velocity in the veſſel AD as the baſe CD to the baſe FG.

Hence we have the momentum wherewith the *fluid* in the tube tends downwards, by multiplying the baſe of the cylinder CD into its altitude CH.

Conſequently, the bottom CD is preſſed with the ſame force, as it would be preſſed by the cylinder HCDI.

To confirm and illuſtrate this doctrine of the preſſure of *fluids* in the ratio of the baſe and altitude, provide a metalline veſſel ACDB (*fig.* 15.) ſo contrived, as that the bottom CD may be moveable, and to that end fitted in the cavity of the veſſel with a rim of wet leather, to ſlide freely without letting any water paſs. For this purpoſe it would be moſt adviſeable, that the moveable bottom ſhould have a groove round its edge, and that it be put into a bladder, tied cloſe round it in the groove by a ſtrong waxen thread; and the bladder may be made to come up like a purſe within the veſſel, and put over the top of it at A and B all round, and then the lid of the veſſel preſſed on it: ſo that when water is poured through a hole in the lid, it would lie upon the bottom CD, and be contained within the bladder. Then, through holes in the top, AB, apply ſucceſſively ſeveral cubes of equal altitudes, but of different diameters. Laſtly, faſtening a ſtring or wire to the beam of a balance, and tying the other end by a little ring K to the moveable bottom, put weights in the other ſcale, till they be ſufficient to raiſe the bottom CD: then will you not only find, that the ſame weight is requiſite, what diameter or magnitude ſoever the tube be of; but even, that the weight which will raiſe the bottom when preſſed by the ſmalleſt tube, will raiſe it when preſſed by the whole cylinder HCDI.

Suppoſe the veſſel ABCD to hold about a pound of water, and that the moveable bottom, wire, and hook, are of equal weight with an empty ſcale M. When this ſcale is pulled down, the bottom CD will be drawn up within the box, and that motion will cauſe the water to riſe in the glaſs tube ELFG. If one pound be put into the ſcale, the bottom will be moved a little, and the water will juſt appear at the lower end of the tube at *o*. Another pound will cauſe it to riſe from *o* to *b*, juſt twice as high above the bottom as it was when at *o*; the preſſure on the bottom being equal to two pounds, the counterbalancing weight in the ſcale M. A third pound will raiſe it to *c*, a fourth to *d*, &c. the diſtances *ab*, *bc*, *cd*, &c. being taken equal to each other and to the depth of the veſſel. If another tube, as *f*, be put into a hole made in the top of the veſſel, and the veſſel be filled with water; and, then, if water be poured in at the top of the tube FGEL, it will riſe in the tube *f* to the ſame height as it does in the other tube: from hence it is evident, that the upward preſſure of the water, riſing in the tube *f*, is equal to the downward preſſure in the other tube FGEL: the caſe would be the ſame, whatever be the number of tubes; and the moveable bottom would ſuſtain the weight of the water in all the tubes, beſides the weight of all the water in the veſſel: and if all the holes to which theſe tubes (FGEL excepted) were fixed be ſtopped up, each pair, thus ſtopped, will be preſſed upward with a force equal to the weight of water in each tube: and, conſequently, the whole upward preſſure againſt the top of the veſſel, ariſing from the weight or downward preſſure of the water in the tube FGEL, will be equal to the weight of a column of water of the ſame height with that in the tube, and of the ſame thickneſs as the width of the inſide of the box or of the moveable bottom; and this upward preſſure againſt the top will reach downward with equal force againſt the bottom.

If the diameter of the moveable bottom be three inches, therefore, and the diameter of the bore of the tube a quarter of an inch, their ſquares will be nine inches and one ſixteenth of an inch; and therefore the whole area of the bottom will be a hundred and forty-four times as great as that of the area of the bottom or top of the tube: ſo that if the moveable bottom be raiſed one inch, the water would be raiſed to the top of a tube a hundred and forty-four inches, or twelve feet in height. The veſſel muſt be open below the moveable bottom to let in the air, whereby the preſſure of the atmoſphere upon it, ſuppoſing its diameter three inches, would require a counterbalance of a hundred and eight pounds in the ſcale M before the bottom would begin to move. See HYDROSTATIC *Balance*.

XII. From the preceding articles, we may eaſily deduce a method of eſtimating the quantity of preſſure of *fluids* on any given ſurface. Let *a b c d* (*fig.* 16.) repreſent a cubical veſſel full of water; the ſide *a c* will, therefore, repreſent a ſquare; and the meaſure of the preſſure on every phyſical point of *a c* will be the altitude of the water above that point; thus, the preſſure on *l* is meaſured by *a l*, on *m* by *a m*, &c. and the preſſure on the whole line will be meaſured by the ſum of as many altitudes *a l*, *a m*, &c. as there are points in the line *a c*. Erect perpendiculars *l e*, *m f*, &c. reſpectively equal to *a l*, *a m*, &c. and the ſum of theſe perpendiculars will be the meaſure of the whole preſſure on the line *a c*: but the ſum of theſe is equal to the area of the triangle *a c d*; and this is as the ſquare of its altitude *a c*. When *a c* repreſents a ſquare, the triangle *a c d* muſt repreſent a priſm, having the ſaid triangle for its baſe, and the ſide of the ſquare for its altitude: the weight of that priſm of water is, therefore, equal to the preſſure made againſt the ſquare, or ſide of the cube; which, as the priſm is half the cube, is equal to half the weight of the whole water contained in the veſſel; and as ſuch ſide bears the ſame degree of preſſure, all the four ſides ſuſtain four times half the weight, or twice the whole weight of the water: and becauſe the bottom ſuſtains a preſſure equal to the whole weight of the water, the bottom and ſides of a cubical veſſel taken together ſuſtain a preſſure from the water contained in it equal to thrice its weight. The ſame obſervations may be eaſily applied to planes that are oblique to the horizon; and we may conclude univerſally, that the preſſure upon any plane, of whatever figure and ſituation, is equivalent to the weight of a ſolid of water, formed by erecting perpendiculars upon every point of the plane propoſed, equal to the reſpective diſtances of thoſe points from the upper ſurface of the water; or, the preſſure on any ſurface is equal to the ſum of all the products which are made by multiplying every indefinitely ſmall part of the ſurface into its diſtance from the top of the water. To find the ſum of all theſe products, or a body of water equal to that ſum, is, in moſt caſes, a difficult problem: Stevinus has attempted the ſolution of it in few inſtances, confining himſelf to regular plain ſurfaces. Mr. Cotes has laid down the following univerſal and expeditious rule: the preſſure on any ſurface is equal to the weight of a body of water whoſe magnitude is found by multiplying the ſurface propoſed into the depth of its centre of gravity under water; and the preſſure on any number of ſurfaces of different bodies, however differently ſituated, is equal to the weight of a body of water whoſe magnitude is found by multiplying the ſum of all thoſe ſurfaces into the depth of their common centre of gravity under water. The demonſtration of this rule depends on the following theorem, viz. that the ſum of the products, ariſing from multiplying every indefinitely ſmall part of any ſurface, or number of ſurfaces, reſpectively, into its perpendicular diſtance from any propoſed plane, will be equal to the product of the whole ſurface or number of ſurfaces multiplied into the perpendicular diſtance of the centre

of gravity of any *single surface*, or of the common centre of gravity of the whole number of surfaces from the same plane. Thus, let a, b, c, d, (*fig.* 17.) represent weights, hanging at their centres of gravity a, b, c, d, by the lines ae, bf, cg, dh, fixed to a horizontal plane e, f, g, h; and let n be the common centre of gravity of all the weights, and no its perpendicular distance from the said plane. Let r be the common centre of gravity of a and b, and to nr, drawn parallel to the said plane, let am and bn be perpendicular. In the similar triangles mrn and mrb, $nr : mr :: mb : ab : a$. See CENTRE *of Gravity*. Therefore $a \times mr = b \times nr$, i. e. $a \times me - re = b \times ne - re$, and, consequently, $a \times me + b \times re = a + b \times re$. In the common centre of gravity of a and b suppose a weight $= a + b$, and a weight $p = r + c$ in the common centre of gravity of r and c, and a weight $= r + d$, in the common centre of gravity of p and d. Then n is the common centre of gravity of a, b, c, d. And we have (as above) $a \times ke + b \times ke = a \times re$, and $a \times re + c \times re = p \times re$, and $p \times oe + d \times oe = n \times oe$: consequently $a \times ae + b \times be + c \times ce + d \times de = n \times oe$. And this will be the case, if the suspended lines $a e$, &c. be perpendicular to any plane, though not parallel to the horizon. Now taking the upper surface of water for that plane to which we refer the indefinitely small parts of the surface which is exposed to the pressure we are concerned with; since it has been already shewn, that the pressure upon the whole is equivalent to the weight of a body of water which is equal in magnitude to the sum of all the products, made by multiplying every little part by its distance from the upper plane of the water; and that this sum of products is exactly equal to the product of the whole surface or number of surfaces multiplied into the distance of the centre of gravity from the upper plane of the water; it will follow, that the same product is the measure of a magnitude of water, whose weight is equivalent to the pressure required. See Cotes's Hydrost. Lect. 3.

For the laws of the pressure and gravitation in FLUIDS specifically heavier, or lighter, than the bodies immerged, see GRAVITY, *Specific*.

For the laws of the resistance of FLUIDS, or the retardation of solid bodies moving in *fluids*, see RESISTANCE.

For the ascent of FLUIDS in capillary tubes, or between glass planes, see ASCENT and CAPILLARY *Tubes*.

The motions of *fluids*, and particularly water, do also make the subject of hydraulics.

FLUIDS, *Hydraulic Laws of*. I. The velocity of a *fluid*, as water, moved by the pressure of a superincumbent *fluid*, as air, is equal at equal depths, and unequal at unequal ones.

For the pressure being equal at equal depths, the velocity arising thence must be so too; and vice versâ: yet the velocity does not follow the same proportion as the depth, notwithstanding that the pressure, whence the velocity arises, does increase in the proportion of the depth. But here the quantity of the matter is concerned: and the quantity of motion, which is compounded of the ratio of the velocity and quantity of matter, is increased in equal times as the squares of the velocities.

II. The velocity of a *fluid* arising from the pressure of a superincumbent *fluid*, at any depth, is the same as that which a body would acquire in falling from a height equal to the depth; as is demonstrated both from mechanics and experiments. See DISCHARGE.

III. If two tubes of equal diameters, full of any *fluid*, be placed in any position, either erect, or inclined, provided they be of the same altitude, they will discharge equal quantities of the *fluid* in equal times.

That tubes, every way equal, should, under the same circumstances, empty themselves equally, is evident; and that the bottom of a perpendicular tube is prelled with the same force as that of an inclined one, when their altitudes are equal, has already been shewn. Whence it easily follows, that they must yield equal quantities of water, &c.

IV. If two tubes of equal altitudes, but of unequal apertures, be kept constantly full of water, the quantities of water they yield in the same time, will be as the diameters; and this, whether they be erect, or any way inclined.

Hence, if the apertures be circular, the quantities of water emptied in the same time, ought to be in a duplicate ratio of the diameters.

But this law, Mariotte observes, is not perfectly agreeable to experiment. If one diameter be double the other, the water flowing out of the less is found more than a fourth of what flows out of the greater. But this may have been owing to some accidental irregularities in making the experiments.

Wolfius however ascribes it principally to this, that the column of water directly over the aperture is sometimes thinner than that next the sides or parietes of the vessel: for the water, in its efflux, forms a kind of cavity over the aperture; that part immediately over it being evacuated first, and the other water not running so much from the sides to supply it. Now, this cavity, or diminution of altitude, being greater in the greater tube, than in the less; hence the pressure, or endeavour to pass out, becomes proportionally less in the greater tube than in the less.

V. If the apertures E and F of two tubes AB and CD (*fig.* 18. and 19.) be equal, the quantities of water, discharged in the same time, will be as the velocities.

VI. If two tubes have equal apertures E and F, and unequal altitudes AB and CD, the quantity of water discharged from the greater AB will be to that discharged from CD, in the same time, in a subduplicate ratio of the altitudes AB and CD.

Hence, 1. The altitude of the water, AB, and CD, discharged through equal apertures E and F, will be in a duplicate ratio of the velocities acquired in the same time.

And as the quantities of water are the velocities, the velocities are likewise in a subduplicate ratio of their altitudes.

Hence, 2. The ratio of the waters discharged by two tubes AB, and CD, together with the altitude of one of them, being given, we have a method of finding the altitude of the other, viz. by finding a fourth proportional to the three given quantities; which proportional, multiplied by itself, gives the altitude of CD, required.

Hence, also, 3. The ratio of the altitudes of two tubes of equal apertures being given, as also the quantity of water discharged by one of them, we have a method of determining the quantity the other should discharge in the same time.

Thus, to the given altitudes, and the square of the quantity of water discharged at one aperture, find a fourth proportional. The square root of this will be the quantity of water required.

Suppose, e. gr. the height of the tubes as 9 to 25, and the quantity of water discharged at one of them, three inches; that discharged by the other will be $= \sqrt{\frac{9 \times 25}{9}} = \sqrt{25} = 5$.

VII. If the altitude of two tubes AB and CD be unequal, and the apertures E and F be likewise unequal, the quantities of water, discharged in the same time, will be in a ratio compounded of the simple ratio of the apertures, and the subduplicate one of the altitudes.

And hence, if the quantities of water discharged in the same time by two tubes, whose apertures and altitudes are unequal, be equal, the apertures are reciprocally as the roots of the altitudes, and the altitudes in a reciprocal ratio of the squares of the apertures.

VIII. If the altitudes of two tubes be equal, the water will flow out with equal velocity, however unequal the apertures be.

IX. If the altitudes of two tubes, AB and CD, as also their apertures, E and F, be unequal, the velocities of the waters discharged are in a subduplicate ratio of their altitudes.

And hence, 1. As the velocities of waters flowing out at equal apertures, when the altitudes are unequal, are also in a subduplicate ratio of the altitudes, and as this ratio is equal if the altitudes be equal, it appears in the general, that the velocities of waters flowing out of tubes, are in a subduplicate ratio of their altitudes.

Hence also, 2. The squares of the velocities are as the altitudes.

Mariotte found, from repeated experiments, that if a vessel ABCD have a tube EG fitted to it, there will more water be evacuated through the tube, than there could have been, in the same time, through the aperture of the vessel E without the tube; and that the motion of the *fluid* is accelerated so much the more, as the tube EG is the longer.

E. gr. The altitude of a vessel AC being one foot, that of the tube EG three feet, and the diameter of the aperture three lines, no less than 6½ septiers of water were discharged in the space of one minute; whereas, upon taking off the tube, only four septiers were discharged. Again, when the length of the tube EG was six feet, and the diameter of the aperture G an inch, the whole quantity of water run out in thirty-seven seconds; but cutting off half the tube, the vessel was not evacuated in less than forty-five seconds; and, taking it quite away, in less than ninety-five seconds.

X. The altitudes and apertures of two cylinders full of water being the same, one of them will discharge double the quantity of water discharged in the same time by the other, if the first be kept continually full, while the other runs itself empty; for the velocity of the full vessel will be equable, and that of the other will be continually

nually retarded. Now it is demonſtrated, that, if two bodies be impelled by the ſame force, and the one proceeds equably, and the ſecond is equably retarded, by that time they have loſt all their motion, the one has moved double the ſpace of the other.

XI. If two tubes have the ſame altitudes, and equal apertures, the times wherein they will empty themſelves, will be in the ratio of their baſes.

XII. Cylindric and priſmatic veſſels, as ABCD (*fig.* 20.) empty themſelves by this law, that the quantities of water diſcharged in equal times decreaſe, according to the uneven numbers, 1, 3, 5, 7, 9, &c. taken backwards.

For the velocity of the deſcending level FG is continually decreaſing in the ſubduplicate ratio of the decreaſing altitudes; but the velocity of a heavy body deſcending, increaſes in the ſubduplicate ratio of the increaſing altitudes. The motion, therefore, of the level FG, in its deſcent from G to B, is the ſame as if it were to deſcend in the inverſe ratio from B to G; but, if it deſcend from B to G, the ſpaces, in equal times, would increaſe, according to the progreſſion of the uneven numbers; conſequently the altitudes of the level FG, in equal times, would decreaſe, according to the ſame progreſſion inverſely taken.

Hence, therefore, the level of water FG deſcends by the ſame law, as, by an equal force impreſſed, it would aſcend through an altitude equal to BG.

From this principle, many other particular laws of the motion of *fluids* might be demonſtrated, which, for brevity ſake, we here omit.

To divide a cylindrical veſſel into parts, which ſhall be evacuated in certain parts or diviſions of time, ſee CLEPSYDRA.

XIII. If water deſcending through a tube HE (*fig.* 21.) ſpout up at the aperture G, whoſe direction is vertical, it will riſe to the ſame altitude GI, at which the level of the water LM, in the veſſel ABCD, does ſtand.

For ſince the water is driven through the aperture G by the force of gravity of the column EK, its velocity will be the ſame as that with which a body, by the ſame force impreſſed, would riſe to the altitude FI: wherefore, ſince the direction of the aperture is vertical, the direction of the water ſpouting through it, will be ſo too; conſequently the water muſt riſe to the height of the level of the water LM in the veſſel.

Indeed, by the experiment, it appears, that the water does not riſe quite ſo high as I: beſides, the aperture G ſhould be ſmaller, as the height of the level of the water is leſs; and even ſmaller when mercury is to be ſpouted than when water. But this is no objection to the truth of the theorem; it only ſhews, that there are certain external impediments, which diminiſh the aſcent. Such are, the reſiſtance of air, and the friction of the tube, &c. See JET *d'Eau*.

XIV. Water, deſcending through an inclined tube, or a tube bent in any manner, will ſpout up, through a perpendicular aperture, to the height of which the level of the water in the veſſel ſtands.

XV. The lengths or diſtances DE and DF, or IH and IG, (*fig.* 22.) to which water will ſpout either through an inclined, or an horizontal aperture D, are in a ſubduplicate ratio of the altitudes in the veſſel or tube AB and AC.

For ſince water, ſpouted out through the aperture D, endeavours to proceed in the horizontal line DF, and, at the ſame time, by the power of gravity, tends downwards in lines perpendicular to the former; nor can the one power hinder the other, inaſmuch as the directions are not contrary; it follows, that the water, by the direction BA, will arrive at the line IG in the ſame time wherein it would have arrived at it, had there been no horizontal impulſe at all. Now, the right lines IH and IG are the ſpaces which the ſame water would have deſcribed in the mean time by the horizontal impetus; but the ſpaces IH and IG, inaſmuch as the motion is uniform, are as the velocities: conſequently the velocities are in a ſubduplicate ratio of the altitudes AB and AC; and therefore the lengths or diſtances, to which the water will ſpout in apertures either horizontal or inclined, are in a ſubduplicate ratio of the altitudes.

That the velocities are in the ſubduplicate ratio of the altitudes may be ſhewn by experiment: for, let two pipes as C and *g*, of equal ſized bores, be fixed into the ſide of the veſſel AB, (*fig.* 23.) and let the pipe *g* be four times as deep below the ſurface of the water at *h*, in the veſſel, as the pipe C is; and whilſt theſe pipes run, let the water be conſtantly poured into the veſſel, to keep the ſurface at the ſame height. Then a veſſel holding a pint, applied to the ſpout C, and another containing a quart, at the ſpout *g*, will be filled at the ſame time. The horizontal diſtance, to which a *fluid* will ſpout from an horizontal pipe, in any part of the ſide of an upright veſſel, below the ſurface of the *fluid*, is equal to twice the length of a perpendicular to the ſide of the veſſel, drawn from the mouth of the pipe to a ſemicircle deſcribed upon the altitude of the *fluid*; and therefore, the *fluid* will ſpout to the greateſt diſtance poſſible from a pipe, whoſe mouth is at the centre of the ſemicircle; becauſe a perpendicular to its diameter (ſuppoſed parallel to the ſide of the veſſel) drawn from that point, is the longeſt that can poſſibly be drawn from any part of the diameter to the circumference of the ſemicircle. Thus, if the veſſel AB, *fig.* 23. be full of water, the horizontal pipe D be in the middle of its ſide, and the ſemicircle *N e d c h* be deſcribed on D as a centre, with the radius D *c* N, or D *f h*, the perpendicular D*d* to the diameter D N*h* is the longeſt that can be drawn from any part of the diameter to the circumference *N e d c h*. And if the veſſel be kept full, the jet G will ſpout from the pipe D to the horizontal diſtance N M, which is double the length of the perpendicular D *d*. If two other pipes, as C and E, be fixed into the ſide of the veſſel at equal diſtances above and below the pipe D, the perpendiculars C*c* and E*e*, from theſe pipes to the ſemicircle, will be equal; and the jets F and H, ſpouting from them, will each go to the horizontal diſtance N K, which is double the length of either of the equal perpendiculars C*c* or E*e*. Ferguſon's Lect. p. 70.

Hence, as every body, projected either horizontally or obliquely, in an unreſiſting medium, deſcribes a parabola; water projected either through a vertical or inclined ſpout, will deſcribe a parabola.

Hence we have a way of making a delightful kind of water arbours, or arches, viz. by placing ſeveral inclined tubes in the ſame right line.

On theſe principles are formed various hydraulic engines for the raiſing, &c. of fluids, as pumps, ſyphons, fountains, or jets d'eau, &c. which ſee deſcribed under their proper articles PUMP, SYPHON, FOUNTAIN, SPIRAL, SCREW, &c.

For the laws of the motion of FLUIDS, by their own gravity, along open channels, &c. ſee RIVER, and WAVE, and *Motion* of WATER.

For the laws of preſſure and motion of air, conſidered as a FLUID, ſee AIR, and WIND.

FLUIDS. Animalcules obſerved in *fluids* are of divers kinds; ſome are flat, others eel-like, but the greater part of an oval figure. Leewenhoeck gives a deſcription of a very unuſual ſhaped creature, fixed in a little ſeabhard or ſheath, which was fattened to ſome of the ſmall green weeds found in ditches full of water. Phil. Tranſ. N° 337. p. 160.

Waters of all kinds, that have ſtood a while expoſed to the air, till they have grown a little putrid, or where putrefaction has been promoted by the admixture of other matters, abound in variety of animalcules, having each their peculiar characters, ſizes, figures, oeconomy, and method of life, not to ſay uſes. In a ſmall drop of the diſcoloured ſurface of rain-water, which had ſtood two months in a window, Dr. Harris obſerved four ſorts of animalcules: the clear part of the drop preſented two kinds, both very ſmall; the firſt of the figure of ants-eggs: theſe were in a continual briſk motion. The ſecond more oblong, three times as long as broad, were exceedingly numerous, but their motion ſlow.

In the thick part of the drop there were alſo two ſorts of animalcules. The firſt of the eel-kind, reſembling thoſe in vinegar, but much ſmaller, and with their extremes more ſharp. Theſe would wriggle out into the clear part, and then ſuddenly betake themſelves back again, and hide in the thick and muddy part of the drop, much like common eels in the water. The ſecond ſort reſembled a large maggot, which would contract themſelves into a ſpherical figure, and then ſtretch out again. The end of the tail appeared with a forceps, like that of an ear-wig. They might be plainly perceived to open and ſhut their mouths, from whence air-bubbles were frequently diſcharged. The number of theſe was not above four or five. The ſame four kinds of animalcules he alſo found in many other drops of the ſame corrupted water. Animalcules in *fluids* are generally found at the top. In the lower parts of the water, Dr. Harris aſſures us he could never find any, unleſs when the liquor had been diſturbed, and the ſurface ſhaken down, and mingled with the lower parts. Dr. Harris examined ſome rain-water that had ſtood uncovered a little while, but had not contracted any thick or diſcoloured ſcum.

And here, where the water was clear, he could not find any animals at all; but a little thin white ſcum, like greaſe, began to appear in its ſurface, he found to be a congeries of exceeding ſmall animals of different ſhapes and ſizes, much like thoſe produced by ſteeping barley in water.

Viewing a ſmall drop of the green ſurface of ſome puddle

water

water, he found it altogether composed of animalcules of several shapes and magnitudes; the most remarkable were those which gave the water that green colour, and were oval creatures, whose middle part were of a grass-green, but each end clear and transparent. They could contract and dilate themselves, tumble over and over many times together, and then shoot away like fishes. Phil. Trans. N° 220, p. 235.

Dr. Harris looked on the surface of some mineral chalybeate water, which stood in a vial unstopt for about three weeks. In it he saw two kinds of animals, one exceeding small, and the other very large, which latter sort had on the tail something that looked like fins. There were but very few of either sort. Phil. Trans. N° 220, p. 257. seq.

Animalcules in *fluids* are eafily deftroyed by only feparating them a while from their element. Naturalifts have even found fhorter ways. A needle-point dipped in fpirit of vitriol, and then immerged into a drop of pepper-water, readily kills all the animalcules, which, though before ftriking about with great fpecimals and activity, no ftoner come within the influence of the acid particles, than they fpread themfelves, and tumble down to all appearance dead. The like may be done by a folution of falt, only with this difference; that by the application of this latter, they feem to grow vermicular, turning round and round, till they fall down. Tincture of falt of tartar oiled in the fame manner kills them ftill more readily; yet not fo, but there will be apparent marks of their being fick ftill and convulfed. Take deftroy them as faft as fpirit of vitriol, and human blood, by virtue of the falt contained in it, produces the fame effect. Urine, fack, and fugar, do all deftroy them, though not fo faft; befides, that there is fome diverfity in their figures and appearances, as they receive their deaths from this poifon or that. The point of a pin dipped in fpittle prefently killed all the kinds of animalcules in puddle water, as Dr. Harris fuppofes it will other animalcules of this kind. Phil. Trans. N° 203. p. 863, feq. and N° 220. p. 236.

We find in the wants of our ditches many fpecies of fmall animalcules, both of the cruftaceous and teftaceous kinds. The legs of the creatures are fhort, they refemble thofe of crabs and lobfters, but are of a much more curious ftructure; they are lefs than a fmall flea, but they feem all breeders, carrying fpawn at their tails, or in two fmall bags, one hanging from each fide. Thefe bags are often feen broken, and the fpawn is then found to conift of globules very large in proportion to the fize of the creature. There is another fort befide thefe, as beautiful, but much fmaller than they; this in fhape more refembles the fhrimp, and carries its fpawn as the fhrimp does. Their kinds both feem only to have one eye, and that placed exactly in the middle of their forehead, without the leaft trace of a dividing line; and they are often fo tranfparent, that the motion of their bowels, and pulfation of their heart, may be feen. Baker's Microfcope, p. 93.

All who are acquainted with the microfcope, know very well, that in water, in which the beft glaffes can difcover no animated particle of matter, after a few grains of pepper, or a fmall fragment of a plant of almoft any kind, has been fome time in it, animals full of life and motion are produced, and thofe fo numerous as to equal the *fluid* itfelf in quantity.

A fmall quantity of water taken from any ditch in the fummer months, is found to be full of little worms, feeming in nothing fo much as fize to differ from thefe microfcopic animalcules. Nay water, without thefe, expofed in open veffels in the fummer months, will be always found, after a few days, to abound with multitudes of them, vifible to the naked eye, and full of life and motion.

Thefe we know, by their future changes, are the fly-worms of the different fpecies of gnats, opules, and multitudes of the other fly-fpecies, and we can eafily determine, that they have owed their origin only to the eggs of the parent fly there depofited. Now, a clofer obfervation will at any time give undue proof of this; as the flies may be feen laying their eggs there, and thofe eggs may be followed in all their changes to the fly again. Why then are we to doubt but that the air abounds with other flies and animalcules, as minute as the worms in thefe *fluids*? and that thefe laft are only the fly-worms of the former, which after a proper time fpent in that ftate, will fuffer changes like thofe of the larger kinds, and become flies like thofe to whofe eggs they owed their origin? Vide Reaumur. Hift. Infect. vol. iv. p. 431.

The differently macerated liquors, made by the infufions of different plants, afford a proper matter for the worms of different fpecies of thefe fmall flies; and there is no reafon to doubt but among thefe fome are viviparous, others oviparous, and to this muft be a great meafure owing the different time taken up in the production of the infects in different *fluids*. Thofe which are a proper matter for the worms of the viviparous kind may be foonefl found full of them, as probably the latter is no fooner in a ftate to afford them a proper nourifhment than their parents place them there: whereas thofe produced from the eggs of the little oviparous flies muft wait after the liquor is in a proper ftate, and they are depofited in it, in form of eggs, before a proper time can be hatched before they can appear alive.

It is eafy to prove that the fmall eggs are found on thefe vegetable infufions were brought to them from fome other place. It is not lefs eafy to prove that they would not be in the matter infufed, any more than the *fluid* it is infufed in.

Not with ftanding the fcoffings of a tribe of falmanders, it is now well known, that the minuteft, large or fmall, even to the fhorteft time, after a confiderable time; and by means of reafon we are to believe, that any infect, or embryo infect, in any form, can bear the heat of boiling water for many minutes. To proceed to enquiries on this foundation, if feveral tubes filled with water with a fmall quantity of vegetable matter, fuch as pepper, oak-bark, truffles, &c. in which, after a time, infects will be difcovered by the microfcope; and other like tubes be filled with fimple water boiled, with water and pepper boiled together, and with water with the two other ingredients, all feparately boiled in it; when all thefe liquors come to a proper time for the obfervation of the microfcope, all, as well thofe which have been boiled as thofe which have not, will be found equally to abound with infects, and thofe of the fame kind in the infufions of the fame kind, whether boiled or not boiled.

Thofe in the infufions which had fuftained a heat capable of deftroying animal life, muft therefore not have fubfifted either in the water, or in the matter put into it, but muft have been brought thither, after boiling, and it feems by no way fo probable, as by means of fome little winged inhabitants of the air depofiting their eggs or worms in thofe *fluids*.

It is a natural queftion on this to aft, why it is, that while we fee myriads of the progeny of thefe winged infects in water, we feldom fee the infects themfelves? The anfwer is eonally eafy, viz. becaufe we can always place a drop of this water immediately before the focus of the microfcope, and keep it there while we at leifure examine its contents; but that is not the cafe with regard to the air inhabited by the parent flies of thefe our worms, which is of immenfe extent in proportion to the water proper to nourifh thefe worms, and confequently, while the latter are cluftered together in heaps, the former may be difperfed and fcattered. Nor do we want inftances of this even in the infects of a larger kind. In many of our gardens we frequently find veffels of water filled with the gnat-worms, in plentifully in proportion to their fize, as thefe nor *fluids* with animalcules. Every cubic inch of water in thefe veffels contains many hundreds of thefe animals; yet we fee many cubic inches of the air in the garden not affording any one of the parent flies. Id. Ibid. See ANIMALCULES, EEL, VINEGAR, and PEPPER-*water*.

FLUID, *Cauftic*. See CAUSTIC-*fluid*.

FLUID, *Senfitive*. See SENSITIVE-*fluid*.

FLUKE, in *Lithology*, a word ufed in fome parts of England as a name for the PLOUGHSOR.

FLUKE *of an anchor*, that part of it which falleth in the ground. See ANCHOR.

FLUKERS, in *Natural Hiftory*, a name given by the miners in Cornwall, and fome other places, to a fort of greyifh foft earth, in which there are a great number of fmall white ftones of a ftarry nature. They ufually find this mixt fubftance near the places where the loads or veins of ore lie, and it feems evidently to have been waffied from among the broken parts of the ftrata near where the metals lie. It is itfelf a courfe and often foul earth, and the white ftones which it contains, are fometimes fmall cryftalline, but opake pebbles, of the nature of thofe which we find of various fizes in our fand and gravel-pits; but more ufually they are fmall fragments of common fpar, and are of a plated figure when broken, and feem only rounded by the motion of the water, like many fmall ftones which are found in the beds of rivers, and on the fea-fhores. The foft nature of the fubftance of which thefe are compofed makes them eafily liable to be robbed into a round figure.

FLUMMERY, a wholefome fort of vegetable jelly made of oatmeal.

The manner of preparing it is as follows: put in the proportion of three large handfuls of finely ground oatmeal, to ftand for twenty-four hours or more, in two quarts of fair water; then pour off the clear water, and put two quarts

quarts of fresh water to it; strain it through a fine hair-sieve, and boil it till it is as thick as a lady pudding, stirring it continually while it is boiling that it may be very smooth: some sweeten it with sugar, and add rose or orange-flower water; and then eat it with white or Rhenish wine, cream, or milk.

FLUOR, in *Physics*, &c. denotes a fluid; or, more properly, the state of a body, which was before hard and solid, but is now reduced, by fusion, or fire, into a state of fluidity.

Gold and silver will remain a long time in *fluor*, kept to them by the intenseft heat, without losing any thing of their weight. See GOLD, FIXITY, &c.

The word *fluor* is applied to fignify the habitual fluidity of any fubftance, or that property by which a fubftance cannot be rendered folid, and is employed as an epithet, to diftinguifh fuch fubftances from others of the fame kind, but which are habitually folid, or which may be rendered folid.

Thus, acids, which are habitually fluid, as all the mineral and fome vegetable acids, are called *fluor* acids, in order to diftinguifh them from the acid of tartar and acid eflential falts, which are naturally concrete. Alfo volatile alkali treated with quick lime, or with metallic earths, fo that it is always liquid and not cryftallized, is called *fluor* volatile alkali, to diftinguifh it from the concrete and cryftallizable volatile alkali. See ACID *Fluor*.

FLUOR is alfo ufed, by the modern mineral writers, for fuch foft, tranfparent, fparry kinds of mineral concretions, as are frequently found amongft ores and ftone, in mines and quarries.

Thefe are of a ftony nature, and refemble gems, but are lefs hard, and are called *metallic fluors and fpars*.

FLUOR *Albus*, or *Uterinus*, a kind of flux, incident to women, popularly called the *whites*.

It conftits in an irregular, diforderly difcharge of fome corrupt humour from the uterus, near the os internum and the vagina, fometimes white and pale, like whey; fometimes yellow, green, or blackifh. At firft, it is ufually mild, and harmlefs; but in time, it grows hot, fharp, and corrofive, and excoriates all the parts it touches. It is attended with a pain in the fpina dorsi, a fwelling of the feet and eyes, weaknefs, fhmbago, a lofs of appetite, loathings, and unaccountable longings, change of complexion, &c.

It generally proceeds from a relaxed habit, arifing from indolence, extreme grief, or the immoderate ufe of coffee, tea, or other weak and watery diet; and fometimes from exceflive menftrual difcharges, abortions, &c.

The immediate caufes of a *fluor albus*, are debility of the veffels from which the menftrual difcharge is made, or a retarded circulation of the blood through them. In fome languid habits, the *fluor albus* returns periodically, inftead of the proper menftrual evacuation, till the patient's conftitution is invigorated; and in many inftances, it is manifeft only during the abfence of the menfes.

It muft be carefully diftinguifhed from an ulcer in the uterus, and a gonorrhœa, which laft it greatly refembles. It happens to all ages, from girls of three years old; and at all times, before, after, or even along with, the menfes, and even to women with child.

Thofe that are moft fubject to this diforder, are women abounding with ferum, thofe of lax fibres, women at the flower of their age, and girls at the approach of the menfes.

Etmuller takes it for a gonorrhœa molleris, analogous to a non-virulent gonorrhœa in men, flowing out of the glandulæ of the proftates.

What the coryza is in the noftrils; too much weeping in the eyes; and coughing and hawking in the fauces; that, according to Etmuller, is this *fluor* in the uterus.

According to Pitcairn, all the difference between the venereal gonorrhœa and a *fluor albus*, is, that the humour evacuated in the latter is vifcid, and in the former quite thin and ferous. The fame author adds, that the *fluor albus* can only be cured by medicines proper for the venereal difeafe.

Aftruc diftinguifhes this diforder into the lymphatic, femilacteous, and lacteous: Dr. Sheldeare fays, that the *fluor albus*, the hectic fever, and the diabetes, are of the fame general kind, and that they are caufed by a defect of vital heat in different circumftances.

Other authors diftinguifh this difeafe into two kinds, the benign and the malignant; the firft is fimple, the other complicated with the venereal difeafe. The fimple *fluor albus*, though called benign in comparifon of the other, is yet very difficult to cure, and is always the more fo, the longer it has continued upon the perfon; and very often the common methods by medicine fail, unlefs the caufe and manner of life be changed. But though it is thus difficult of cure, it is of lefs danger than many other diſeaſes, for many women have had it many years, nay a great part of their lives even to old age, and that without any great hurt. Indeed it very rarely grows to that height as to injure the ftrength or health, farther than by a paleneſs of the face, and a ſtupid look, and a laſſitude of the limbs: but if this difcharge, when it has been many years habitual to a perſon, be ſtopped by any improper methods, it often brings on very terrible complaints. The worſt effect of the *fluor albus* is that, when of long ſtanding, it uſually renders women barren; and its principal difficulty of cure is this, that it will often ſeem to give way to medicines, but return afterwards with all its former violence; nay when people ſeem ever ſo perfectly cured of it, it often returns, and the whole method is to be gone through again. The *fluor albus*, while it only attends the flowing of the menſtrual diſcharges, is a thing of no great moment; but when thoſe diſcharges ſtop, and this matter becomes more acrid, and is voided in larger quantities, it then becomes a diſeaſe that calls for all the art of the phyſician to remedy it; for, in ſome perſons, it brings on finally hectics and waſting of the fleſh, and in others cachexies, œdemas, and dropſies.

Method of cure. When this diſeaſe happens to a perſon of a plethoric habit, the firſt ſtep toward a cure is bleeding in the foot to diſcharge part of the load of blood, leſt nature ſhould make that an occaſion of conveying a great part of it into uterum, and throwing it upon the uterus for its diſcharge. After bleeding, an abſtenſion of the matter of the diſeaſe, and a ſucceſſive evacuation of it are to be attempted, by the more temperate uterine medicines, the gentle emmenagogues and cleanſers; ſuch are amber, myrrh, and turpentine. The ſecond of theſe is to be given, but in moderate doſes, and the laſt ſucceeds beſt after boiling, or when mixt with maſtic. The digeſtive ſalts are alſo to be given, and nitre in this caſe often proves a very beneficial medicine. The aperient roots, ſuch as lovage, pimpernel, and the like, are to be given in decoction, and the leaves of bean and ſouthernwood are no ineffectual remedies; and finally the gums are to be added, ſuch as galbanum, ammoniacum, and ſagapenum. After theſe aſtringents and preparatory medicines, gentle purges are to be given, and finally ſuch medicines as reſtore the due tone of the parts: of this nature are the milder chalybeats, and decoctions of the nervous and aromatic herbs; ſuch as roſemary, origanum, fernyſtom, and the like. Junker's Conſ. Med. p. 472. The diet of the patient ſhould be ſolid and nouriſhing, but eaſy of digeſtion: her drink generous, as red port or claret, mixed with Pyrmont, Briſtol, or lime-water. Ptiſans diſſolved in milk, ſtrong broths, and a milk diet, have been of conſiderable ſervice: tea and coffee ſhould be avoided. The beſt medicine is the Peruvian bark in ſubſtance; and the cold bath is extremely uſeful. Dr. Cheyne recommends mild mercurials to alter, chalybeats to invigorate, and the bark and cold bathing for completing the cure.

Dr. Morgan thinks the *fluor albus* is the lymph corrupted, and aſſures us, that the tincture of cantharides, given in a pretty ſtrong decoction of guaiacum, has good effects when the diſtemper is recent, but when it is of long ſtanding and inveterate, recourſe muſt be had to mercurials.

FLUSH *Deck*. See DECK.

FLUSHER, in *Ornithology*, the common name of the leſſer BUTCHER-*bird*, called by authors the lanius minor, and the lanius tertius of Aldrovand. Its beak is black, long, and very ſtrong, and a little hooked at the end: the mouth is yellow within, and the tongue jagged. It has ſeveral ſhort briſtles at the top of the beak. The middle of its back and ſmaller feathers of its wings are of a reddiſh brown; its head and rump grey: it has a broad black line on each ſide of the head, running from the angle of the beak; its belly is white; its throat and breaſt whitiſh, with a caſt of red. Its wing-feathers are brown and black, and its legs and feet of a deep bluiſh black. It builds in holly-buſhes and ſuch places, and lays ſix oblong eggs, white at the ſmaller end, and ornamented with a circle and reddiſh ſpots at the other. It is common in Germany and in the northern parts of England. Ray's Ornith. p. 54.

FLUTA, in *Ichthyology*, a name given by Gaza and ſome authors, to the common SYARUS, diſtinguiſhed by Artedi, by the name of the plain yellowiſh SPARUS, with a large annular black ſpot near the tail.

FLUTA is alſo a name given by Columella to the murena of Ariſtotle, and the ancient authors in general, as well Greek as Roman. It makes only one ſpecies of the murena, according to Artedi; but being with him a generical name, which comprehends all the eel-kind, the *ſerpens marinus* and the like, among theſe. This, which

was anciently called simply the murena, is distinguished by that author under the name of the murena having no pectoral fins; which being peculiar to this species, evidently and obviously distinguishes it at first sight from all the rest.

FLUTE, an instrument of music, the simplest of all those of the wind-kind; played, by blowing it with the mouth; and the tones or notes formed and changed by stopping or opening holes disposed for that purpose all along it. Those in common use are either the *flute abec*, i. e. a beaked or common English *flute*, and the traverse, Helvetian, or German *flute*, the invention of which is ascribed by Galileo and Mersenne to the Helvetians: but the antique statue of the piping faun, and a tessellated pavement of Fortuna Virilis, erected by Sylla at Rome, in which is a representation of a young man playing on a traverse pipe, with an aperture to receive his breath, shew that it is of more ancient original.

The Latins call it *fistula*, and sometimes *tibia*, pipe; from the former of which, some derive the word *flute*: though Borel will have it derived from *flute*, a lamprey, thus called a *flectibus in flutem*; in regard the *flute* is long like the lamprey, and has seven holes all along it, like that fish. Hawkins's Mus. p. 120.

The ancient *fistulæ*, or *flutes*, were made of reeds; afterwards they were of wood; and at length of metal. But how they were blown, whether as our *flutes*, or hautboys, does not appear.

Mons. Cassilion apprehends that they were sounded by means of a reed; and that there were two sorts of them, in one of which the reed was visible, as in our hautboy, but concealed in the other. Berlin. Mem. 1774. vol. v.

It is plain, some had holes, which at first were but few; but afterwards were increased to a greater number; and some had none. Some were single pipes, and some a combination of several, particularly Pan's syringa, which consisted of seven reeds, joined together sideways.

These seven reeds had no holes, each giving but one note, in all seven distinct ones; but at what intervals, is not known: perhaps they were the notes of the natural, or diatonic scale.

The German *flute* is different from the common ones: it is not put into the mouth, by the end, as the ordinary ones are; the end is stopped up with a plug or tampion, but the lower lip is applied to a hole a little way distant from it.

It is made equally big every where, and perforated with six holes, besides that of the mouth, and that opened by the key.

FLUTE, or FLUYT, is also a kind of long vessel, with flat ribs, or floor-timbers, round behind, and swelled in the middle; serving chiefly for the carrying of provisions to fleets, or squadrons of ships: though it is often used in merchandize.

The word *flute* taken for a sort of boat, or vessel, is derived according to Borel, from the ancient *flotte*, a little boat. In the verbal process of the miracle of St. Catherine of Sweden, in the xiith century, we read, *Unus equum suum una cum mercibus magni pondetis introduxit super instrumentum de lignis fabricatum, vulgariter dictum flute*. Upon which the Bollandists observe, that in some copies it is read *flotta*, an instrument called by the Latins *ratis*; and that the word *flutte*, or *flotta*, arose from *flottare*, or *ottare*, to float.

FLUTE, in *weaving tapestry*. See TAPESTRY.

FLUTES, or FLUTINGS, in *Architecture*, are perpendicular channels, or cavities, cut along the shaft of a column, or pilaster. See *Vitr. Archit. lib.* 25, 26.

They are supposed to have been first introduced in imitation of the plaits of women's robes; and are therefore called by the Latins, *strigæ* and *rugæ*.

The French call them *cannelures*, as being excavations; and we *flutes*, or *flutings*, as bearing some resemblance to the musical instrument so called.

They are chiefly affected in the Ionic order, in which they had their first rise; though they are also used in all the richer orders, as the Corinthian and Composite; but rarely in the Doric; and scarce ever in the Tuscan.

Their number is usually twenty-four, though in the Doric it is only twenty.

Each *flute* is hollowed exactly in a quadrant of a circle.

Between the *flutes* are little spaces that separate them, called, by Vitruvius, *strix*, and by us, *fillets*; though in the Doric, the *flutes* are frequently made to join each other, without any intermediate space at all, the fillet being sharpened off to a thin edge, which forms a part of each *flute*.

In some buildings we see columns with *flutes* that go winding round the shaft, spirally; but this is rather looked on as an abuse.

Vignola determines the depth of the *flutes*, by taking the angle of an equilateral triangle for the centre. Vitruvius describes it from the middle of the square, whose side is the breadth of the *flutes*; which last method makes them deep. The *flutes*, or *strigæ*, are frequently filled up with a prominent, or swelling ornament, sometimes plain, in form of a staff, or reed; and sometimes a little carved, or enriched, in imitation of a rope, or otherwise, and therefore called *rudentures*, or CABLINGS; and the columns, thus enriched, are called *rudted columns*.

This is most frequent in the Corinthian order. The cablings, or fillings up, commence from about one third of the height of the column, reckoning from the base; and are continued to the capital: that is they begin and end with the diminution of the column.

FLUTES, or *Flutings*, are also used in *Botany*, to denote the stems and fruits of certain plants, which have furrows analogous to those of these columns.

FLUVIALIS, in *Botany*, the name given by Vaillant and Micheli to a genus of plants, called by Linnæus NAJAS.

FLUVIATILES *testæ*, fresh-water *shell-fish*, a term used by naturalists to express those kinds of shell-fish which never inhabit the sea, but are found in our ponds, rivers, and ditches. These, though much less numerous than the species of sea-shells, are yet of a greater variety and beauty than is usually supposed. What are known at present, may be arranged under their proper heads in the following manner. See *Syst. Nat.* *Testa*. N° 30.

Of the univalve kinds we have two species of patellæ: the one having a beak at the summit of the shell: the other wanting it, and being smooth as the common patellæ or limpets of the sea.

Of the *limaces* or snails we have five species; of the fresh water *nerita* we have three kinds; one species of the *trochus*; three species of the *turbo*; seven species of the water *buccina*; four species of the *dolia*, or *conchæ globosæ*; four species of the *cornu ammonis*; of the bivalve fresh water shells, we have five species of the *ostrea* kind; six species of the muscle kind.

Of the *pecten* kind we have only one species.

Of the multivalve shells, there is not one known species.

The reducing of the several species to their proper genera is easy, from a remembrance of the characters of each genus of the marine shells. The limpet is a flat shell elevated into a sort of a cone at the summit. Of the snail kind, if the mouth be round, the shell is a true limax; when it is semicircular, the shell is a nerita; and when it is oval or depressed, and the clavicle is long, it is then a trochus. The turbo, or screw-shell, is known by its long and slender figure. The buccina are long shaped, and have a tail, and their mouth is narrow; and the dolia are of a somewhat globose figure. The cornu ammonis, and the umbilicated snail, are often confounded together by those who observe their external resemblance among the fresh water shells; but they are in reality sufficiently different, the cornu ammonis being marked on the outside with circular ridges, and divided on the inside into several separate cells, like the common fossile kinds; whereas the umbilicated snail is of an even external surface, and has only one cavity within. The snail also has its mouth placed toward one side, the CORNU *ammonis* in the middle: there are other differences, but these are sufficient for the distinction. The *ostreæ* are known by their roundish figure; the muscles by being oblong; and the *pecten* is known by its ears and its *striæ*. Hist. Nat. Eclair. p. 375. See SHELLS.

FLUX, FLUXUS, in *Medicine*, an extraordinary issue, or evacuation of some humour.

Fluxes are various, and variously denominated, according to their seats, or the humours thus voided; as a *flux* of the belly, uterine *flux*, hepatic *flux*, salival *flux*, &c.

The *flux* of the belly is of four kinds, which have each their respective denominations, viz. the LIENTERY, or *fluxus lientericus*; the COELIAC, or *fluxus chyliformis*; the DIARRHŒA; and the DYSENTERY, or bloody *flux*.

A wound or scarification across the crown of the head, is used in Scotland to cure *fluxes* and dysenteries. Philosoph. Transf. N° 313.

The bishop of Cloyne, in his reflexions on tar-water, says, he has known a *bloody flux* of long continuance, after divers medicines had been tried in vain, cured by TAR-*water*. But what he takes to be the most speedy and effectual remedy in a *bloody flux*, is a clyster of an ounce of common brown rosin, dissolved over a fire in two ounces of oil, and added to a pint of broth, which not long since he had frequent occasion of trying, when that distemper was epidemical. Nor can he say that any to whom he advised it miscarried.

FLUX, *abortive*, *fluxus abortivus*, is sometimes used among the ancients as synonymous with abortions or effluctions, viz. where the embryo loses its hold and slips away. In this sense, the eagle-stone is celebrated for stopping *abortive* fluxes; for which end it was to be hung to the arm, *subnexus sperm uteri defensale a fluxibus abortivis*. See ÆTITES.

Among

Among modern physicians, *abortive fluxes* are chiefly understood of a kind of hæmorrhages, which sometimes precede, and bring on abortion; at other times, burst forth in the act of exclusion.

In this sense, a late author defines them a species of uterine hæmorrhages, happening to married women; when, after a stoppage of the menses, for three or four months successively, with a gradual swelling of the abdomen, and other signs of pregnancy, the blood begins to issue from the womb, at first sparingly, like the regular menses, but afterwards, bursts out with great force, attended with anxieties, fainting fits, and sometimes with miscarriage.

The cause is a violent separation of the secundines from the uterus, which may arise from a vehement fit of passion, or motion of the body, a fall, fright, or the like. Thunder, lightning, hot liquors, too liberal use of deobstruents, or the navel-string being too short, sometimes occasion an *abortive* hæmorrhage.

FLUX *of the mouth*, or *salival flux*. See SALIVATION.

The *hepatic* FLUX of the ancients, is, by several moderns, held a mere name; being, in reality, an hæmorrhoidal *flux*, out of the hæmorrhoidal veins. See HEPATIC *Flux*.

Women are subject to three kinds of *fluxes* extraordinary: the first, called the MENSES, or *menstrual flux*, as happening every month; sometimes *courses*, as keeping pace with the moon; and sometimes *flowers*.

The second is after delivery, called LOCHIA.

The third is irregular, and preternatural; and, for want of a better name, called FLUOR *albus*, or the *whites*.

FLUX, in *Hydrography*, a regular, periodical motion of the sea, happening twice in twenty-four hours; wherein the water is raised, and driven violently against the shores.

The *flow*, or *flow*, is one of the motions of the TIDE: the other, whereby the water sinks and retires, is called the *reflux*, or *ebb*.

There is also a kind of rest, or cessation of about half an hour, between the *flux*, and reflux: during which time the water is at its greatest height, called *high-water*.

The *flux* is made by the motion of the water of the sea, from the equator towards the poles; which, in its progress, striking against the coasts in its way, and meeting with opposition from them, swells, and where it can find passage, as in flats, rivers, &c. rises up, and runs into the land.

This motion follows, in some measure, the course of the moon; as it loses, or comes later every day by about three quarters of an hour; or more precisely, by forty-eight minutes: and by so much is the motion of the moon slower than that of the sun. It is always highest and greatest in full moons, particularly those of the equinoxes. In some parts, as at Mount St. Michael, it rises eighty or ninety feet, though in the open sea it never rises above a foot or two; and in some places, as about the Morea, there is no *flow* at all. It runs up some rivers above a hundred and twenty miles. Up the river Thames it only goes eighty, viz. near to Kingston in Surry.

Above London-bridge, the water flows four hours, and ebbs eight; and below the bridge, flows five hours, and ebbs seven.

FLUXES, in *Metallurgy*, are certain saline matters, which cause a body otherwise not at all, or hardly fusible by fire, to melt. Fixed alkalis, nitre, borax, tartar, and common salt, are the saline matters of which *fluxes* are generally composed.

The most powerful of these, are glass of lead, and the alkaline and neutral salts. These are principally used by assayers, when they would work minerals in a small quantity; but when large quantities of minerals are to be wrought on, it is seldom possible to use *fluxes* of this kind to any advantage, because of their prices. In these cases, instead of these expensive *fluxes*, they use such stones as are vitrified by a gentle fire, or the scoriæ made of the same stones when melted, which always serve their purposes much better; for the other these stones have been exposed to the fire, the more easily are they put in fusion: the reason of which seems to be, that the alkaline salt proceeding from the fuel of the fire, adheres to the scoriæ; and these added in large quantities to the rest of the metals in great operations, cause the said ores to melt, which are otherwise made refractory by the calcareous and incombustible stones and earths mixed with them.

The melting of gold and silver, and of their calces, is greatly promoted by glass of lead, alkaline salts, &c. but when gold and silver in the fusion itself, are to be purged from other metals and semimetals, it is proper to use nitre only; or if not so, nitre must be always mixed with the other salts; for the semimetals and the four less perfect metals are destroyed by nitre.

In this operation, nitre by its detonation with their sulphurs is in part alkalised, and by the help of a gentle fire, turns their calces into vitreous and much attenuated scoriæ.

From hence, the reason is plain why gold and silver, when made brittle, are readily restored to their malleability by nitre: for the semimetals, and among the metals, lead, and tin, most of all communicate this fault to gold and silver; but these being changed, as before observed, by nitre, are then rejected by gold and silver in a simple fusion, so that they can no long remix with these metals, unless they are themselves first again reduced to their metallic state; and there is besides these, no other body that can be mixed with silver and gold to render them brittle, unless crude charcoal happening to fall into the vessel, wherein those metals are melted, should impregnate them with something arsenical, there being some arsenic contained in coals of this kind; as has been demonstrated by Stahl and Hoffman.

The less perfect metals, and the semimetals melt more easily by adding salts to them, than of themselves; they always, however, lose a great deal of their substance by this means; and this is more particularly the case, in regard to copper and iron. To amend this, it is necessary to add some kind of fat body, which prevents the destruction, and even reduces the metals already destroyed; and this is the more necessary, when the calces prepared either by burning, or by a detonation with nitre, are to be reduced.

The most proper *flux* on these occasions, is that usually known among metallurgists under the name of the *black flux powder*, and is thus prepared.

Take of common nitre, one part, of crude tartar thoroughly dried, two or three parts: make them separately into very fine powder, then grind them well together, and afterwards put them into an earthen pot, narrow at the orifice, not glazed within, and of capacity three times larger than the powder will take up; put this into a gentle fire, and as soon as the mass begins to flame with some noise, shut the orifice of the vessel with a tile; after the detonation is over, you will find in the vessel a black oily alkaline salt, which is very easily fusible in the fire, and is called the *black flux*: keep it in a dry warm place, and in a vessel closely shut, to prevent its growing moist.

Tartar being burnt either alone in vessels closely shut, or detonated with nitre, is very readily alkalised; and thus retains a considerable quantity of the oil which it contains in great abundance, and which is fixed enough to remain with it, after this operation; and for this reason it very easily becomes a reducing *flux*, which, on account of its alkaline salts, diffolves earths and stones, and changes them into an imperfect kind of glass by a moderate melting fire; but the oil being of a more fixed nature, still remains concealed therein, and is of great use both to preserve metals from being destroyed, and to reduce such as have been destroyed already.

If the pot in which this *flux* powder is made be glazed within, and part of the glazing comes off, and mixes with the *flux*, and melts with it, it is again reduced to lead, and may thus disappoint the assayer; for this cruft of glazing is given to earthen vessels by lead or litharge.

Another caution is also necessary; which is, that all *fluxes* must be kept and used very dry; for moist salts foam very much; and when the operations are made in close vessels, if the fire is quickly increased, not being able to get rid of the moisture, the vessels will split and break.

Besides the black, assayers are also very fond of a white *flux* powder, which is prepared only of equal parts of nitre and tartar detonated in the same manner. But in this case the oil of the tartar is almost entirely consumed by the abundance of the nitre, and the remaining mass becomes a whitish or ash-coloured salt; which is also more powerfully alkaline, and sharp than the foregoing. This *flux* is very efficacious in the dissolving of stones, and earths; but for want of its oil as of a less reductive virtue, and destroys the metal, when the fire is continued a little longer than is required.

By crude *flux*, is meant the mixture of nitre and tartar in any proportions, without detonation.

Flux powders are of great service also to reduce metals out of their respective calces, and to free them from the stones in which they are embodied; but when the refractory calx of iron is to be reduced by a great and long lasting fire, these *fluxes* being greatly attenuated, though confined in close vessels, part from their oily principles, and their alkaline salt remaining, begin to corrode and consume the vessels, of what matter soever they are made, and finally make their way through them and get out. The fruit of these accidents is prevented by adding coal dust, which will never part with its oil, without the help of a free air; and the others by an admixture of common glass, made of a due mixture of flints and fixed alkali.

kali. For this is sufficiently fusible, and readily melts with the *fluxes*, and by its viscidity, in some sort coagulates, and holds the salt of the *flux* together, and prevents it from so easily corroding the vessels. Cramer, Art. Ass p. 48, 52.

The great secret in making and improving *fluxes* for the ores of metals, is not only to find such ingredients as will be of efficacy to separate the metal already ripened in the ore, but even to maturate and ripen the yet immature part of it in the fire; and something of this kind we apprehend might be effected, as there is great reason to believe, that certain *fluxes* will obtain a much larger yield of metals from certain ores than other *fluxes* in common use, though esteemed of the best, and perhaps of the dearest kind: thus clean iron filings will often do more than borax, but as the scales and rust of iron have commonly been used under the name of iron in *fluxes*, few operators know the value of pure iron in that intention, and many advantages are now obtained by mixing one ore with another of the same denomination, and with the slags or recrements of metals in the way of a *flux*.

The *fluxes* for the ores of metals seem in general reducible to two kinds, the vitreous and the saline. The vitreous are those which either naturally have a glassy form, or readily assume one as the lead, the principal of these are glass of lead, glass of antimony, and borax.

By the saline *fluxes*, authors generally mean those which are composed of salts, whether tartar, nitre, fixed alkali, or the like, as the black *flux*, fandiver, pot-ashes, and the like. The vitreous *fluxes* seem defined more immediately to act upon the stony or vitrescible matter, where with the stubborn ores are frequently mixed, and the saline kind to act more immediately upon the matter of the ore itself, for the due exclusion or separation of the metal.

The more kindly ores require no *fluxes* at all, and often they contain in themselves the necessary matter for that *flux*; thus there are copper ores, which being only ground to powder, and put into a common wind furnace, will yield as much pure metal at the first operation, as can be produced from them, by all the *fluxes*. Shaw's Lectures, p. 256.

Powder of antimony is a very good *flux* powder. By this alone may you readily melt iron or steel in a crucible, with an ordinary charcoal fire.

Some of the cheapest and most powerful *fluxes* now in use are, dried wine-lees, dried cow-dung, and horse-dung, dried river-mud, sailor's-earth, iron filings, common salt, potash, and fandiver. These may be used in the larger works; as nitre, tartar, borax, sal armoniac, and mercury sublimate, in the assays or for compound *fluxes*, they are very numerous, almost every operator having his particular nostrum; and it is plain that some *fluxes* are better adapted to the ores of some metals than others; but certainly a few general ones might be fixed upon, one or other of which would answer all the operator's expectations.

The three following preparations are all very general, very powerful, and not expensive. 1. Take of nitre, prepared by long boiling in lime-water, of sea-salt melted in the fire, of fandiver, and of dry wine-lees, each one part; glass of lead, three parts, and powdered glass, eight parts; mix them all well together, and use them in an equal weight with stubborn ores. 2. For a still stronger *flux*, take equal parts of white tartar, common salt, and nitre prepared as above; calcine all together to a white powder, and mix with it its own weight of glass of lead: of this *flux* add two parts to one part of the most stubborn ores. 3. For a very powerful saline *flux*, take of the strongest soap-boiler's lees four pounds, of white tartar and common salt, melted in the fire, each one pound; boil these together, with four gallons of human urine, to a dry salt. This *flux* is particularly serviceable where sulphur and cobalt abound, and render the ore very refractory. Shaw's Lectures, p. 257.

FLUXES, in *Enamel-painting*, are used for forming the grounds and colours: there are two kinds of substances which enter the composition of enamel *fluxes*, viz. the vitrifiable matters, which consist of salts, lead and arsenic, and the correctives of these, which are calcined flints, sand, or such calcareous matter, which give body and firmness to the fluxing composition, without discolouring or changing the proper fluxing qualities, unless by diminishing in a degree their vitrifactive power. The most active *flux* among salts is borax, the next is lead; arsenic, joined with some other body already vitrified and hereby fixed, is the next powerful *flux*; and the several kinds of salts succeed, of which sea salt possesses the greatest fluxing power. Though these are not strong enough by themselves, yet, as they are colourless, they are necessary to be compounded with lead, or substituted for it, with the aid of borax, for purposes, in which the *flux* must be wholly destitute of colour. *Fluxes* of all kinds are prepared by levigating the ingredients of which they consist on a porphyry slooe with a mullar of the same matter or of flint; or in a mortar of agate or flint, with an agate pestle; or, for the sake of expedition, a mortar and pestle of the common green glass may be previously used. This levigated matter must be then put into melting pots, and placed in a furnace, where the heat is nearly that of a strong culinary fire; and when the vitrification is perfect, which may be known by the matter's being transparent and free from any bubbles, it must be poured out on an iron plate free from rust, and when cold, powdered and kept for use. See ENAMEL.

FLUXES, in the *Manufactures of Glass*, are red-lead, pearl-ashes, nitre, sea-salt, borax, arsenic the *ferria* of forges, commonly called clinkers, and wood-ashes. See GLASS.

FLUXION, in *Medicine*, a sudden collection of morbid matter in any part of the body.

Fluxions arise either from the weakness, flaccidity, and inactivity of the part affected, which does not disperse, perspire, or expel, the humours naturally received into it; or from the derivation of some extraordinary quantity of peccant matter from some other part.

This latter is properly called DEFLUXION, and, by the ancients, *catarrhus*.

A *fluxion*, or *defluxion*, on the trachea and lungs, is called a CATARRH.

FLUXION, in the *Newtonian Analysis*, denotes the velocity with which a flowing quantity is increased by its generative motion: by which it stands contradistinguished from *fluent* or the *flowing* quantity, which is gradually, and indefinitely increasing, after the manner of a space which a body in motion describes.

Or, a *fluxion* may be more accurately defined, as the magnitude by which any flowing quantity *would be* uniformly increased in a given portion of time, with the generating celerity at any propofed portion, or inftant, fuppoling it from thence to continue invariable.

Thus, if the point M move from A, and generate the right line A *m*. Tab. II. Geometry, *fig.* 26. and the celerity at B be fuch as would be fufficient, fuppoling it to continue uniform from that point, to defcribe the line B *r* in the given time; then B *r* repreſents the *fluxion* of the variable line A *m* in that poſition. The rectangle A S, *fig.* 30. may be conceived to be generated by the parallel motion of the invariable line S A between A F and B G; and ſince R *r* is the *fluxion* of A *m*, the rectangle R *r* ſb will be the ſpace which would be uniformly deſcribed by *m n*, whilſt A *m* would be uniformly increaſed by *m s*, and *n* is, therefore, the *fluxion* of the generated rectangle A B S R. Further, if the curvilineal ſpace A *m n*, *fig.* 31. be generated by the parallel motion of *m n*, conſidered as variable; and R *r* be the *fluxion* of A *m*, the rectangle R *r* s would be uniformly generated with the celerity, with which it begins to be generated, and with which the ſpace A *m n* is increaſed in the poſition R *s*, when the length and velocity of *m n* are ſuppoſed to continue invariable from that poſition, and, therefore, agreeably to the definition, will be the *fluxion* of the generated ſpace A *m n*.

From this definition it appears, that the *fluxions* of quantities are, always, as the celerities by which the quantities themſelves increaſe in magnitude.

Mr. Simpſon obſerves, that there is an advantage in conſidering *fluxions*, not as mere velocities, but as the magnitudes which theſe velocities would, uniformly, generate in a given finite time: the imagination is not here confined to a ſingle point, and the higher orders of *fluxions* are rendered much more eaſy and intelligible. And though Sir Iſaac Newton defines *fluxions* to be the velocities of motions, yet he hath recourſe to the increments or moments, generated in equal particles of time, in order to determine thoſe velocities, which he afterwards teaches us to expound by finite magnitudes of other kinds. Simpſon's *Fluxions*, vol. I. *paſſ.* p. 6. and p. 2, &c.

FLUXIONS, *method of*, is the arithmetic and analyſis of *fluxions*, and fluents, or flowing quantities.

Foreigners uſually deſcribe the method of *fluxions*, the arithmetic, or analyſis, of infinitely, or rather indefinitely, ſmall variable quantities; or the method of finding an infinitiſimal, or infinitely ſmall quantity, which, being taken an infinite number of times, becomes equal to a given quantity.

Sir I. Newton, and, after him, the Engliſh authors, call theſe infinitely ſmall quantities, *moments*; conſidering them as the momentary increments, or decrements, of variable quantities, e. gr. of a line conſidered as generated by the flux of a point, or of a ſurface generated by the flux of a line.

Accordingly, the variable quantities are called *fluents*, or flowing quantities; and the method of finding either the *fluxion*, or the fluent, the method of *fluxions*.

M. Leibnitz conſiders the ſame infinitely ſmall quantities

as the differences, or differentials, of two quantities; and calls the method of finding those differences, the *differential calculus*. Each of these ways of considering and denominating, has its advantages, which the retainers to this or that method strenuously assert.

Flowing quantities, i. e. such as, in the genesis of figures by local motion, are continually increasing and diminishing, are certainly very properly denominated fluents: and as all figures may be conceived as so generated, the infinitely small increments or decrements of such quantities, are very naturally denominated *fluxions*.

Beside this difference in the name, there is another in the notation.

Sir I. Newton expresses the *fluxion* of a quantity, as *x*, by a dot placed over it, as $\dot{x}$; and M. Leibnitz expresses his differential of the same *x*, by prefixing a *d*, as *dx*; each of which methods of notation has likewise its advantage.

Setting aside these circumstances, the two methods are the same.

The method of *fluxions* is one of the greatest, most subtle, and sublime discoveries of this, or, perhaps, of any age: it opens a new world to us, and extends our knowledge, as it were, to infinity; it carries us beyond the bounds that seemed to have been prescribed to the human mind, at least infinitely beyond those to which the ancient geometry was confined.

The history of this important discovery, as fresh as it is, is a little dark, and imbroiled. Two of the greatest men of this age do both of them claim the invention, sir I. Newton, and M. Leibnitz; and nothing can be more glorious for the method itself, than the zeal wherewith the partisans of either side have asserted their title.

To give the reader a just view of this noble dispute, and of the pretensions of each party, we shall lay before him the origin of the discovery, and mark where each claim commenced and how it was supported.

The first time the method made its appearance in public, was in 1684, when M. Leibnitz gave the rules thereof in the Leipsic Acts of that year; but the demonstrations he kept to himself. The two brothers, the Bernoullis, were presently struck with it, and found out the demonstrations, though very difficult; and practised the calculus with surprising success.

However, M. Leibnitz began to propose his differential method in a letter, dated the 21 Jan. 1677, in which he exactly pursues Dr. Barrow's method of tangents, published in 1670: and sir I. Newton communicated his method of drawing tangents to Mr. Collins, in a letter dated 10 Dec. 1672; which letter, together with another dated 13 June, 1676, were sent to M. Leibnitz by Mr. Oldenburgh, in 1676. So that there is a strong presumption that he might avail himself of the information contained in these letters, and other papers transmitted with them, and also in 1675, before the publication of his own letter, containing the first hint of his differential method. And it sufficiently appears, that sir I. Newton had invented his method before the year 1669, and that he actually made use of it in his Compendium of Analysis and Quadrature of Curves before that time. His attention seems to have been directed this way, even before the plague which happened in London in 1665 and 1666, when he was about twenty-three years of age: and, therefore, there is no foundation for the hint suggested by the authors of the Encyclopedie Art. *Differentielle*, that sir Isaac borrowed the differential method from Dr. Barrow.

This is all we hear of it, till the year 1687, when sir Isaac Newton's admirable Principia came forth, which is almost wholly founded on the same calculus.

The common opinion, at that time, was, that sir Isaac, and M. Leibnitz, had each invented it about the same time; and what confirmed it was, that neither of them made any mention of the other; and that, though they agreed in the substance of the thing, yet they differed in their ways of conceiving it, called it by different names, and used different characters.

In effect, M. Leibnitz's character was supposed, by foreigners, to be somewhat more commodious than that of sir Isaac Newton: accordingly, the method soon spreading itself throughout Europe, M. Leibnitz's character went with it; by which means the geometricians were insensibly accustomed to look on him as the sole, or principal inventor.

The two great authors themselves, without any foreseeing concern, or dispute, as to the property of the invention, enjoyed the glorious prospect of the progresses continually making under their auspices, till the year 1699, when the peace began to be disturbed.

M. Fatio, in a treatise Of the Line of swiftest Descent, declared, that he was obliged to own sir Isaac Newton as the first inventor of the differential calculus, and the first by many years; and that he left the world to judge, whether M. Leibnitz, the second inventor, had taken any thing from him. This precise distinction between first and second inventor, with the suspicion it insinuated, raised a controversy between M. Leibnitz, supported by the editors of the Leipsic Acts, and the English geometricians, who declared for sir I. Newton. Sir Isaac himself never appeared on the scene; his glory was become that of the nation; and his adherents, warm in the cause of their country, needed not him to animate them.

Writings succeeded each other but slowly, on either side, probably, on account of the distance of places; but the controversy grew still hotter and hotter: till, at length, it came to such pass, that, in the year 1711, M. Leibnitz complained to the Royal Society, that Dr. Keill had accused him of publishing the method of *fluxions* invented by sir I. Newton, under other names, and characters.

He insisted, that nobody knew better than sir Isaac himself, that he had stolen nothing from him; and required, that Dr. Keill should publicly disavow the ill construction which might be put on his words.

The society, here appealed to as a judge, appointed a committee to examine all the old letters, papers, &c. that had passed among the several mathematicians, relating to the point; and, after a strict examen of all the evidences that could be procured, gave in their report to this purpose: "That Mr. Leibnitz was in London in 1673, and "kept a correspondence with Mr. Collins by means of "M. Oldenburgh, till Sep. 1676, when he returned "from Paris to Hanover, by way of London and Amsterdam: that it did not appear that M. Leibnitz knew "any thing of the differential calculus before his letter "of the 21st June, 1677, which was a year after a copy "of a letter wrote by sir I. Newton, in the year 1672, "had been sent to Paris to be communicated to him, "and above four years after Mr. Collins began to communicate that letter to his correspondents, wherein "the method of *fluxions* was sufficiently explained, to "let a man of his sagacity into the whole matter: and "that sir I. Newton had even invented his method before the year 1669, and, of consequence, fifteen years "before M. Leibnitz had given any thing on the subject "in the Leipsic Acts." And thence they concluded, that Dr. Keill had not at all injured M. Leibnitz in what he had said.

The society printed this censure at large, together with all the pieces and materials relating thereto, under the title of Commercium Epistolicum de Analyi Promota, Lond. 1712. This book was carefully distributed through Europe, to vindicate the title of the English nation to the discovery; for sir Isaac, as already hinted, never appeared in it: whether it were that he trusted his honour with his compatriots, who were zealous enough in the cause; or whether it were that he was even superior to the glory thereof.

M. Leibnitz and his friends, however, could not shew the same indifference: he was accused of a theft, and the whole Commercium Epistolicum either expresses it in terms, or insinuates it. Soon after the publication there of, a loose sheet was printed, at Paris, in behalf of M. Leibnitz, then at Vienna. It is wrote with great zeal and spirit; and maintains, boldly, that the method of *fluxions* had not preceded that of *differences*: and even insinuates, that it might have arisen from it. The detail of the proofs, on each side, would be too long, and could not be understood without a large comment, which must enter into the deepest geometry.

M. Leibnitz had begun to work upon a Commercium Epistolicum, in opposition to that of the Royal Society; but he died before it was completed.

A second edition of the Commercium Epistolicum was printed at London in 1722; where sir Isaac Newton, in the preface, account, and annotations, which were added to that edition, particularly answered all the objections which M. Leibnitz and M. Bernoulli were able to make since the Commercium first appeared in 1712. See also Raphson's Hist. *Fluxions*. From the last edition of the Commercium, and the various original papers contained in it, it evidently appears that Sir Isaac Newton had discovered his method of *fluxion* many years before M. Leibnitz's pretensions.

It must be owned, that there are strong presumptions in favour of M. Leibnitz; presumptions, we mean, that he was no plagiary: for that sir Isaac Newton was the first inventor, is past all dispute; his glory is secure; the reasonable part, even among the foreigners, allow it: and the question is only, whether M. Leibnitz took it from him, or fell upon the same thing with him; for, in his Theory of Abstract Notions, which he dedicated to the Royal Academy, in 1671, before he had seen any thing of sir I. Newton's, he already supposed infinitely small

quantities, some greater than others; which is one of the great principles of the fyſtem.

The doctrine conſiſts of two parts, viz. the *Direct method of fluxions*, called alſo, *Leibnitz differentials*; and the *Inverſe method of fluxions*, or *Cavalus integrals*.

The latter is directly oppoſite to the former; and is a conſequel of it: both of them are adopted into the new geometry, and make reigning methods therein.

The firſt deſcends from finite, to infinite; the latter aſcends from infinitely ſmall, to finite: the one decompounds a magnitude; the other re-eſtabliſhes it.

The foundation of the direct method of *fluxions* amounts to this problem: the length of the ſpace deſcribed being continually (that is, at all times) given, to find the velocity at any time propoſed.

The foundation of the inverſe method of *fluxions* amounts to this problem: the velocity of the motion being continually given, to find the ſpace deſcribed by it at any time propoſed.

Direct method of FLUXIONS. All finite magnitudes are here conceived to be reſolved into infinitely ſmall ones, ſuppoſed to be generated by motion, as a line by the motion of a point, a ſuperficies by a line, and a ſolid by a ſuperficies; and they are the elements, momants, or differences, thereof.

The art of finding theſe infinitely ſmall quantities, or the velocities by which they are generated, and of working on them, and diſcovering other infinite quantities, by their means, makes the direct method of *fluxions*.

What renders the knowledge of infinitely ſmall quantities of ſuch ſignal uſe and extent is, that they have relations to each other, which the finite magnitudes, whoſe they are the infiniteſimals, have not.

Thus v. gr. in a curve, of any kind whatever, the infinitely ſmall difference of the ordinate and abſciſs have the ratio to each other, not of the ordinate and abſciſs, but of the ordinate and tangent; and conſequently, the abſciſs and ordinate alone being known, give the ſubtangent unknown; or, which amounts to the ſame, the tangent itſelf. See the *Inverſe method of* FLUXIONS.

The method of notation in *fluxions*, introduced by the inventor, Sir I. Newton, is thus:

The variable, or flowing quantity, to be uniformly augmented, as ſuppoſe the abſciſs of a curve, he denotes by the final letters v, x, y, z; and their *fluxions* by the ſame letters with dots placed over them, thus, $\dot{v}$ $\dot{x}$ $\dot{y}$ $\dot{z}$. And the initial letters a, b, c, d, &c. are uſed to expreſs invariable quantities.

Again, if the *fluxions* themſelves are alſo variable quantities, and are continually increaſing or decreaſing, he conſiders the velocities with which they increaſe, or decreaſe as the *fluxions* of the former *fluxions*, or ſecond *fluxions*; which are denoted by two dots over them, thus, $\ddot{x}$ $\ddot{y}$ &c.

After the ſame manner one may conſider the augments, and diminutions of theſe, as their *fluxions* alſo; and thus proceed to the third, fourth, fifth, &c. *fluxions*, which will be noted thus, $\dddot{x}$ $\dddot{y}$ $\dddot{z}$ &c. We may obſerve, in general, that the *fluxions* of all kinds and orders whatever, are contemporaneous, or ſuch as may be generated together, with their reſpective velocities in one and the ſame time.

Laſtly, if the flowing quantity be ſurd, as $\sqrt{a-b}$; he notes its *fluxion* $\sqrt{\dot{a}-\dot{b}}$: if a fraction $\frac{x}{d-y}$ he notes it, $\frac{\dot{x}}{d-y}+\frac{x\dot{y}}{\overline{d-y}^2}$. V. Wallis's Algebra, p. 392, apud Oper. vol. ii. See FLUENT.

The chief ſcope and buſineſs of *fluxions* is, from the flowing quantity given, to find the *fluxion*: for this we ſhall lay down one general rule, as ſtated by Dr. Wallis, and afterwards apply and exemplify it in the ſeveral caſes.

"Multiply each term of the equation ſeparately by the "ſeveral indices of the powers of all the flowing quan-"tities contained in that term; and in each multiplica-"tion, change one root or letter of the power into its "proper *fluxion*: the aggregate of all the products con-"nected together by their proper ſigns, will be the *fluxion* "of the equation deſired.

The application of this rule will be contained in the following caſes. I. To expreſs the *fluxions* of ſimple variable quantities, as already mentioned, you need only put the letter, or letters, which expreſs them, with a dot over them: thus, the *fluxion* of x is $\dot{x}$, and the *fluxion* of y is $\dot{y}$, and the *fluxion* of $x+y+z$, is $\dot{x}+\dot{y}+\dot{z}$, &c.

Note, For the *fluxion* of permanent quantities, when any ſuch are in the equation, you muſt imagine c, or x cypher; for ſuch quantities can have no *fluxion*, properly ſpeaking, becauſe they are without motion, or invariable.

Again, the *fluxion* of a quantity, which decreaſes, inſtead of increaſing, is to be conſidered as negative.

II. *To find the* FLUXION *of the product of two or more variable or flowing quantities*.—Multiply the *fluxion* of each ſimple quantity by the factors of the products, or the product of all the reſt; and connect the laſt products by their proper ſigns; then the ſum, or aggregate, is the *fluxion* ſought.

Thus the *fluxion* of xy, is $x\dot{y}+y\dot{x}$. For, let two right lines, DE and FG, move parallel to themſelves from two other right lines, BA and BC, *Tab. Geometry, fig.* 32. and generate the rectangle DF. Let them always interſect each other in the curve BHR, and let Dd ($\dot{x}$) and Ff ($\dot{y}$) be the *fluxions* of the ſides BD (x) and BF (y); and draw dm and fn parallel to DH and FH. The *fluxion* of the area BDH (ſee the beginning of this article) is Dm or $y\dot{x}$, and that of the area BFH is Fn or $x\dot{y}$, and therefore the *fluxion* of the whole rectangle $EF=xy=BDH+BFG$ will be $x\dot{y}+y\dot{x}$. The *fluxion* of yz is $y\dot{z}+z\dot{y}+y\dot{z}$; for if x be put $=yz$, then $\dot{x}\dot{z}$ will be $=\dot{y}\dot{z}$, and its *fluxion* $=\dot{y}\dot{z}+\dot{x}\dot{y}$; but x being $=yz$, and $\dot{x}=\dot{z}y+\dot{y}z$, by ſubſtitution, will be $=y\dot{z}+\dot{y}z+\dot{x}\dot{y}$. And the *fluxion* of xyz, is $xy\dot{z}+x\dot{y}z+\dot{x}yz=\dot{x}yz+x\dot{y}z+xy\dot{z}$, and the *fluxion* of $a+x\times b-y$ (the common product being $ab+bx-ay-xy$) will be $b\dot{x}-y\dot{a}-x\dot{y}-\dot{x}\dot{y}$.

III. *To find the* FLUXION *of a fraction*.—Multiply the *fluxion* of the numerator by the denominator, and from this product ſubtract the *fluxion* of the denominator drawn into the numerator; this will be the numerator, and the ſquare of the denominator will be the denominator of the fraction expreſſing the *fluxion* of the given fraction.

Thus the *fluxion* of $\frac{x}{y}$ is $\frac{x\dot{y}-y\dot{x}}{y\overline{y}}$.

For ſuppoſe $\frac{x}{y}=z$, then will $x=yz$, which equal quantities muſt have equal *fluxions*; therefore $\dot{x}=y\dot{z}+z\dot{y}$ and $\dot{x}-z\dot{y}=y\dot{z}$; and dividing all by y, $\frac{\dot{x}-z\dot{y}}{y}=\dot{z}=\frac{\dot{x}-\frac{x}{y}\times\dot{y}}{y}$ (becauſe $\frac{x}{y}=z$) $\frac{\dot{x}-\frac{x\dot{y}}{y}}{y}=\frac{\frac{y\dot{x}-x\dot{y}}{y}}{y}=\frac{y\dot{x}-x\dot{y}}{y\overline{y}}$; wherefore this laſt is the *fluxion* of the fraction $\frac{x}{y}=z$; becauſe z being $=\frac{x}{y}$, $\dot{z}$ will be equal to the *fluxion* of $\frac{x}{y}$.

And the *fluxion* of $\frac{a}{x}$ will be $\frac{-a\dot{x}}{x\overline{x}}$; for the permanent quantity a having no *fluxion*, there can be no product of the *fluxion* of the numerator into the denominator, as there would have been, had a been v, z, or any other variable quantity.

IV. *To find the* FLUXION *of a power*.—Multiply the *fluxion* of the root by the exponent of the power, and the product by that power of the ſame root, whoſe exponent is leſs by unit than the given exponent; and likewiſe by the invariable quantity and co-efficient, if there be any.

Thus, the *fluxion* of $x\,x$ will be $2\,x\dot{x}$; for $xx=x\times x$; but the *fluxion* of $x\times x=\dot{x}\times x+x\times\dot{x}=2\,x\dot{x}$, &c. and the *fluxion* of x^3 will be $3\,x\dot{x}$. That of x^4 will be $4\,x^3\dot{x}$, &c. that of $5\,x^3$ will be $25\,x^2\dot{x}$; that of $3\,ax^4$ will be $12\,ax^3\dot{x}$.

Or if m expreſs the index of any power, as ſuppoſe x^m; its *fluxion* will be $m\,x^{m-1}\dot{x}$.

If the power be produced from a binomial, &c. as ſuppoſe $x+y^2$, or $xx+2xy+yy$, its *fluxion* will be $2\times x+y\times\dot{x}+\dot{y}$, or $2\,\dot{x}x+2\,x\dot{y}+2\,\dot{y}y$.

If the exponent be negative, as ſuppoſe x^{-m} or $\frac{1}{x^m}$ its *fluxion* will be $-m\,x\,\dot{x}^{-m-1}$.

Or, if you would do it by way of fraction, $\frac{-m\,x^{m-1}\dot{x}}{x^{2m}}$ (for the ſquare of x^m is x^{2m}) $=-m\,x^{m-1-2m}\dot{x}=-mx^{-m-1}\dot{x}$, as before; $=$, removing $+x^{-m-1}$ to the denominator, by changing the ſign of the exponent, $\frac{-m\dot{x}}{x^{m+1}}$.

If the power be imperfect, i. e. if its exponent be a fraction, as ſuppoſe $\sqrt[n]{x^m}$; or in the other notation $x^{\frac{m}{n}}$, ſuppoſe $x^{\frac{m}{n}}=z$: then if you raiſe up each member to the power of n, it will ſtand thus, $x^m=z^n$; the *fluxion* of which will be, by this general rule, $m\,x^{m-1}\dot{x}=n\,z^{n-1}\dot{z}$.

Where-

Wherefore $\dot{z}$ will be $= \frac{mx\dot{x}}{nz^{n-1}}$ (by dividing both parts by $n\dot{z}^{n-1}$) and $\frac{m\dot{x}}{n\dot{z}^{n-1}} = \frac{x^{m-1}}{z^{n-1}} \times \frac{\dot{x}}{\dot{z}} \times \frac{x}{z}$ or $\frac{m}{n}\sqrt{}$: x^{m-1}; putting, instead of x^{m-1}, its value $z^{\frac{mn-m}{n}}$, and the above expreſſion will become $\frac{m}{n}\dot{x} \times \frac{z^{\frac{mn-m}{n}}}{z^{n-1}} = \frac{m}{n}\dot{x} \times z^{\frac{mn-m}{n}-n+1} = \frac{m}{n}\dot{x} \times z^{\frac{mn-n-mn+m}{n}} = \frac{m}{n}\dot{x} \times z^{\frac{m-n}{n}} = \frac{m}{n}\dot{x}\sqrt[n]{z^{m-n}}$. Or, more briefly, according to the rule, the *fluxion* of $\sqrt[n]{x^m}$ or $x^{\frac{m}{n}}$ will be $\frac{m}{n} \times \dot{x} \times x^{\frac{m}{n}-1} = \frac{m}{n}\dot{x}x^{\frac{m-n}{n}}$, &c.

V. *To find the* FLUXIONS *of ſurd quantities.* Suppoſe it required to find the *fluxion* of $\sqrt{2rx-xx}$, or $2rx-xx)^{\frac{1}{2}}$. Suppoſe $2rx-xx)^{\frac{1}{2}} = z$; then is $2rx-xx = zz$; and conſequently $r\dot{x}-x\dot{x} = z\dot{z}$; and, by diviſion, $\frac{r\dot{x}-x\dot{x}}{z} = \dot{z} =$ (by ſubſtitution) $\frac{r\dot{x}-x\dot{x}}{\sqrt{2rx-xx}} =$ to the *fluxion* of $\sqrt{2rx-xx}$.

Or, by the preceding rule, the *fluxion* of $\overline{2rx-xx}^{\frac{1}{2}}$ will be $\frac{1}{2} \times 2rx-2x\dot{x} \times \overline{2rx-xx}^{-\frac{1}{2}} \cdot 1 = \frac{r\dot{x}-x\dot{x}}{\overline{2rx-xx}^{\frac{1}{2}}} = \frac{r\dot{x}-x\dot{x}}{\sqrt{2rx-xx}}$. See POWER.

If it be required to find the *fluxion* of $\overline{ay-xx}^{\frac{3}{2}}$; ſet $ay-xx)^{\frac{1}{2}}$ put z; then $ay-xx = zz$; and $a\dot{y}-2x\dot{x} = 2z\dot{z} = 2z\sqrt{ay-xx}$; and multiplying by $\frac{3}{2}$, $\frac{3}{2}a\dot{y}-3x\dot{x} = 3z\sqrt{ay-xx}$, and conſequently, $\frac{3}{2}a\dot{y}-3x\dot{x} \times z = z^3$ equal (ſubſtituting $ay-xx)^{\frac{3}{2}} = z^3$) $\frac{3}{2}a\dot{y}y-3x\dot{x}y$ to the *fluxion* of $ay-xx)^{\frac{3}{2}}$.

VI. *To find the* FLUXION *of quantities compounded of rational and ſurd quantities.*—Let it be required to find the *fluxion* of $bx^3+cx\sqrt{ax+ax}+e$. Put $ax+ax = pp$, and $\sqrt{ax+ax} = p$. Then the given quantity is $\frac{bx^3+cxp+e}{a}$, and the *fluxion* thereof is $\frac{3bx^2\dot{x}+c\dot{x}p+cx\dot{p}}{a}$. But $\dot{p} = \frac{a\dot{x}+a\dot{x}}{2\sqrt{ax+ax}}$, and $p\dot{p} = \frac{a\dot{x}+a\dot{x}}{2}$; therefore, in the equation $p\dot{p}+q\dot{p} = \dot{z}$, if in the place of p, $\dot{p}$, q, $\dot{q}$, we reſtore the quantities they repreſent, we ſhall have $\frac{2a\dot{x}+a\dot{x}}{2\sqrt{ax+ax}} + 2b\dot{x}x \times \sqrt{ax+a} + c\dot{x}\sqrt{ax+a} \times \sqrt{ax+a} = \dot{z}$. Which being reduced to one denomination, gives $\frac{3bx^2+2cx^2}{+cx+a} + \frac{2b\dot{x}x+cx\dot{x}}{\sqrt{ax+a}} = \dot{z} =$ to the *fluxion* of the given quantity.

VII. *To find the* FLUXION *of a logarithm.* The *fluxion* of the hyperbolic logarithm of any quantity is equal to the *fluxion* of that quantity divided by the quantity itſelf: e. gr. the *fluxion* of the hyperbolic logarithm of x is $= \frac{\dot{x}}{x}$: for let LQ *Tab.* II. *Analyſis, fig.* 40. be an hyperbola, whoſe aſymptotes are OR and OS, and whoſe parameter is AL = AO = 1: draw an ordinate PM parallel to AL, and the ſpace APML will be the hyperbolic logarithm of the line OP; and, therefore, the *fluxion* of the ſpace APML will be equal to the *fluxion* of the *hyperbolic* LOGARITHM of the line OP. But the *fluxion* of this ſpace, OP being $= x$, and PM $= y$, is $= y\dot{x}$, and OP : AO $::$ LA : MP by the nature of the curve; i. e. $x : 1 :: 1 : y = \frac{1}{x}$; therefore $y\dot{x} = \frac{\dot{x}}{x}$. Then, from the nature of LOGARITHMS, the hyperbolic logarithm of 10 (viz. 2.30258, &c.) is to the common logarithm of 10 (viz. 1) as the hyperbolic logarithm of any number x to the common logarithm of the ſame number x; i. e. L being made $= 2.30258$, &c. L : 1 :: the hyperbolic logarithm of x to common logarithm of x: and therefore L : 1 :: the *fluxion* of the hyperbolic logarithm of x: the *fluxion* of the common logarithm of x : i. e. L : 1 :: $\frac{\dot{x}}{x} : \frac{\dot{x}}{Lx}$, which is the *fluxion* of the common logarithm of x, or becauſe $\frac{1}{L} = 0.43429$, &c. the modulus of the Brigean or common form of logarithms, if $\frac{1}{L}$ be $= M$, the *fluxion* of the common logarithm of x (viz. $\frac{\dot{x}}{Lx}$) will be $= \frac{\dot{x}}{x} \times M$; or, the *fluxion* of the hyperbolic logarithm of any number multiplied by M or 0.43429, &c. is $=$ the *fluxion* of the common logarithm of the ſaid number.

VIII. *To find the* FLUXION *of an exponential or percurrent quantity*, i. e. of a quantity having a variable exponent, as y^x. Suppoſe $y = ax$; then, by the properties of logarithms, $x \times \log. y = \log. a$. And finding the *fluxions* of theſe terms, $\dot{x} \times \log. y + \frac{M}{y}\dot{y} \times x = \frac{M}{a}\dot{a}$, M being as in the preceding article: conſequently, the *fluxion* of y^x or $a = \frac{a\dot{x}}{M} \times \log. y + \frac{\dot{y}x}{y} = \frac{x}{M} \times y^{x-1} \times \log. y + xy^{x-1}\dot{y}$.

IX. *To find the* FLUXION *of a rectangle, when one ſide is increaſing, and the other decreaſing.* In this caſe the *fluxion* of the decreaſing quantity is negative with reſpect to that of the increaſing quantity (for the beginning of this article), and therefore, the ſign of the term affected with it ought to be changed; or the *fluxion* of the rectangle xy in theſe circumſtances will be expreſſed by $x\dot{y}-y\dot{x}$.

X. *To find the ſecond, third, &c.* FLUXION *of a flowing quantity.* Theſe *fluxions* differ in nothing, except their order and notation, from firſt *fluxions*, being actually ſuch to the quantities from which they are immediately derived; and therefore, they may be found, in the ſame manner, by the general rules already delivered.

Thus, by the 4th rule, the firſt *fluxion* of x^3 is $3x^2\dot{x}$; and if x be ſuppoſed conſtant, or if the root x be generated with an equable celerity, the *fluxion* of $3x^2\dot{x}$, or $3\dot{x} \times x^2$, will be $3\dot{x} \times 2x\dot{x} = 6x\dot{x}^2$, which is the ſecond *fluxion* of x^3; and $6\dot{x}$ will be its third *fluxion*: but if the celerity with which x is generated be variable, either increaſing or decreaſing, then $\dot{x}$, being variable, will have its *fluxion* denoted by $\ddot{x}$, &c. In this caſe the *fluxion* of $3x^2\dot{x}$ will be, by the 2d and 4th rules, $6x\dot{x} \times \dot{x} + 3x^2\ddot{x} = 6x\dot{x}^2 + 3x^2\ddot{x}$, the ſecond *fluxion* of x^3. And the third *fluxion* of x^3, obtained in like manner from the laſt, will be $6\dot{x} \times \dot{x}^2 + 6x \times 2\dot{x}\ddot{x} + 6x\dot{x} \times \ddot{x} + 3x^2\dot{x} = 6\dot{x}^3 + 18x\dot{x}\ddot{x} + 3x^2\dot{x}$. Thus alſo, if $y = x^{n-1}$, then $\dot{y} = n\dot{x} \times x^{n-2} + n\dot{x}x^{n-2}$, and if $\dot{x}^2 = \dot{x}\dot{y}$, then $2\dot{x}\ddot{x} = \dot{x}\dot{y} + \dot{y}\dot{x}$, &c.

FLUXIONS, *inverſe method of, or calculus integralis*, conſiſts in finding finite magnitudes, from the infinitely ſmall parts thereof, and in determining the variable quantity or fluent from the velocity with which it flows at any point or term aſſigned, or the given *fluxion*.

It proceeds, as already obſerved, from infinitely ſmall quantities to finite; and recompounds and ſums up what the other has reſolved: whenceit is alſo called, by ſome, *the ſummatory calculus*.

But what that has decompounded, this does not always re-eſtabliſh; ſo that the inverſe method is limited and imperfect, at leaſt hitherto; if it were once complete, geometry would be arrived at its laſt perfection.

To give an idea of its nature and office, take the inſtances already propoſed in the direct method: in that the infinitely ſmall quantities of the ordinates and abſciſſe, being known, give the ſubtangent required; in this, on the contrary, the ſubtangent of an unknown curve being had, gives the infinitely ſmall quantities of the abſciſſa and ordinate which produced it, and, of conſequence, the abſciſſa and ordinate themſelves; which are finite magnitudes, in whoſe relation the whole eſſence of the curve is founded.

But the diſtinguiſhing uſe of this method is in meaſuring. The baſe of a parallelogram multiplied by the infinitely ſmall element of its altitude, gives an infinitely ſmall parallelogram; which is the element of the finite parallelogram, and is repeated an infinity of times therein, i. e. as many times as there are points in the height of the parallelogram.

To have the finite parallelogram, therefore, by means of its element, the element muſt be multiplied by the altitude; which is the inverſe method of *fluxions*, re-aſcending from the infinitely ſmall quantity to the finite.

Such a circuit of infiniteſimals, it is true, would be impertinent, in ſo ſimple a caſe; but when we have to do with ſurfaces terminated by curves, the method then becomes neceſſary, or, at leaſt, ſuperior to any other.

Suppoſe, e. gr. in a parabola, the ſpace included between two infinitely near ordinates, an infinitely ſmall portion of the axis, and an infinitely little arch of the curve; it is certain, this infinitely ſmall ſurface is no parallelogram; ſince the two parallel ordinates which terminate it on one ſide are not equal; and the arch of the curve, oppoſite to the little portion of the axis, is frequently neither equal nor parallel thereto; and yet this ſurface, which

which is no parallelogram, may be considered, in the strictest geometry, as if it really were one, because it is infinitely small; and the error, of consequence, infinitely little, i. e. none.

So that, to measure it, there needs nothing but to multiply an ordinate of the parabola by the infinitely small portion of the axis corresponding thereto. Thus we have the element of the whole parabola; which element being tallied, by the inverse method, to a finite magnitude, is the whole surface of the parabola.

This advantage, so peculiar to the geometry of infinites, of being able, without any error, to treat little arches of curves as if they were right lines; curvilineal spaces, as if rectilineal ones, &c. enables it not only to go with more ease and readiness than the ancient geometry, to the same truths, but to reach a great number of truths which were inaccessible to the other.

Its operations, in effect, are more easy, and its discoveries more extensive; and simplicity and universality are its distinguishing characters.

The preceding observations are more properly applicable to the method of *fluxions*, in which magnitudes of various kinds are capable of increase, not by a repeated accession of parts, but by a continued motion or flux. See the sequel of this article.

FLUXION *given, to find the flowing quantity belonging to it.* To have the doctrine of the inverse method correspond and keep pace with that of the direct, we will apply it in the same cases.

1. In the general to express the variable quantity of a *fluxion*, there needs nothing but to write the letters without the dots, or to substitute the variable or flowing letter for its *fluxion*. Thus the flowing quantities of $\dot{x}$, $\dot{y}$, $\dot{z}$, are x, y, z.

2. To find the fluent of a compound fluxional expression consisting of the products of two or more flowing quantities drawn into their *fluxions*; or which consists of the *fluxion* of each quantity drawn into the other, or product of the rest of the quantities.

Multiply the flowing quantities together; and the product is the fluent required. E. gr. the fluent of $x\dot{y}+y\dot{x}$ is $=xy$; of $x\dot{y}z+x\dot{z}y+\dot{x}yz=xyz$, &c.

3. To find the *fluxion* of a fraction. The following rule will serve in many cases. Divide the last term in the numerator by the *fluxion* of the negative square root of the denominator; then divide this quotient by the affirmative square root of the denominator for the required fluent.

Thus, the fluent of $\frac{x\dot{y}-y\dot{x}}{y^2}$ is $=\frac{x}{y}$.

4. To find the fluent of an expression compounded of different fluxionary terms connected together by the signs + and −.

Find the separate fluents of the different terms, and connect them together by the signs of their respective *fluxions*. Thus, the fluent of $a\dot{x}+\dot{x}y+x\dot{y}-\frac{y\dot{y}-x\dot{y}}{y^2}$ is $=ax+xy-\frac{x}{y}$.

5. To find the flowing quantity belonging to the *fluxion* of any power, either perfect, or imperfect. Take the fluxionary letter, or letters, out of the equation; then augment the index of the *fluxion* by 1, or unity: lastly, divide the *fluxion* by the index of its power so increased by unity.

Thus suppose $3x^2\dot{x}$ proposed; by taking away $\dot{x}$ it will be $3x^2$; and by increasing its index by unity, it will be $3x^3$; then dividing it by 3, its now (augmented) index, the quotient will be x^3, the flowing quantity required.

Again, the fluent of $\frac{n}{m}x^{\frac{n-m}{m}}\dot{x}$ will be $=x^{\frac{n}{m}}$. In compound fluxionary expressions, if the fluxionary part is equal, or in an invariable ratio to the *fluxion* of the quantity under the vinculum, the fluent may be had by adding 1 to the index of the power, and dividing by the *fluxion* of the quantity under the vinculum drawn into the index of the power thus increased. E. gr. the *fluent* of $\overline{x+x^2}^3\times 3\dot{x}+6x\dot{x}$ is $=\frac{\overline{x+x^2}^3\times 3\dot{x}+6x\dot{x}}{3\times 1+2x}=$ $\frac{\overline{x+x^2}^3}{1+2x}$: the fluent of $\overline{a+x^n}^m\times d\dot{x}^{n-1}\dot{x}$ is $=\frac{\overline{a+x^n}^{m+1}\times d\dot{x}^{n-1}\dot{x}}{m+1\times n\dot{x}\dot{x}^{n-1}}=\frac{\overline{a+x^n}^{m+1}\times d}{n\times m+1}$; and the fluent of $\overline{a+x^n}^m\times x^{n-1}\dot{x}$ is $=\frac{\overline{a+x^n}^{m+1}}{m\times n+1}$.

By these methods the fluent is found when the *fluxion* is given; and the rules are derived from those of the direct method; as the rules in division and evolution in algebra are deduced from those of multiplication and involution. As when a fluent consists of a variable and invariable part, the latter does not appear in the *fluxion*; so when any *fluxion* is proposed, it is only the variable part of the fluent that can be derived from it. If x represent any *fluxion* that may be proposed, the variable part of the fluent will be equal to x; for supposing y to be any variable quantity, if $x+y$ could represent the fluent of x, then $\dot{x}+\dot{y}$ would be equal to $\dot{x}$, and $\dot{y}=o$, or y would be invariable, against the supposition. But supposing K to represent any invariable quantity, then $x+K$ may generally represent the fluent of x. If it be required to find such a fluent of x as shall vanish when x is supposed to vanish, it can be no other than x; and if it be required that the fluent should vanish when x is equal to any given quantity a, then by supposing $x+K$ to vanish when x becomes equal to a, we shall have $a+K=o$, or $K=-a$; whence the fluent is $x-a$. In the same manner, the fluent of $-x$ may be generally represented by $K-x$. When a *fluxion* that is proposed coincides with any of those which were deduced from their fluents in the preceding articles, the variable part of the fluent required must coincide with that which was there proposed. As division in algebra leads us to fractions, and evolution to surds; so the inverse method of *fluxions* leads us often to quantities that are not known in common algebra, and that cannot be expressed by common algebraic symbols. Maclaurin's Flux. art. 735.

We cannot here pretend to enter into a detail of the rules of the inverse method of *fluxions*. We shall only observe in general, that a *fluxion* being proposed, its fluent may sometimes be found accurately in algebraic terms; but this is far from being always possible; and recourse must sometimes be had to a converging series. Thus, if $x^{n-1}\dot{x}$ were proposed, the variable part of the fluent is found by adding unity to the exponent of the power, dividing by the exponent thus increased, and by the *fluxion* of the root; that is, the invariable part of the *fluent* of $x^{n-1}\dot{x}$ will be $\frac{x^{n-1+1}}{n\times 1}=\frac{x^n}{n}$. But in many cases this fluent requires the addition or subtraction of some constant quantity to render it complete, which can only be known from the nature of the problem under consideration; e. gr. the fluent of $x^{n-1}\dot{x}$ may be either represented by x^n or by $x^n\pm a$, because a being constant, the *fluxion* of $x^n\pm a$, as well as of x^n is $nx^{n-1}\dot{x}$. To find this invariable quantity that must be added or subtracted, is to correct the fluent. In order to do this, the best way is to consider how much the variable part of the fluent, first found, differs from the truth, in that particular circumstance when the required quantity which the whole fluent ought to express is equal to nothing: then, that difference added to or subtracted from the variable part, as occasion requires, will give the fluent truly corrected. For, since the difference of two quantities flowing with the same celerity, or having equal *fluxions*, is either nothing at all, or constantly the same, the difference in that circumstance will likewise be the difference in all other circumstances; and, therefore, being added to the lesser quantity, or subtracted from the greater, both become equal. Let the variable quantities x and y be first supposed to begin their existence together or to be generated at the same time: e. gr. 1. Let $y=a^nx\dot{x}$, the fluent will be $y=\frac{a^nx^n}{2}$; if $y=o$, $\frac{a^nx^n}{2}$ vanishes, because x is also $=o$, and the fluent needs no correction. 2. Let $y=\overline{a+x}^1\times\dot{x}$; and y will be $=\frac{\overline{a+x}^2}{2}$; but when $y=o$ and $x=o$, $\frac{\overline{a+x}^2}{2}$ becomes $=\frac{a^2}{2}$; and, therefore, $\frac{\overline{a+x}^2}{2}$ always exceeds y by $\frac{a^2}{2}$, and the fluent properly corrected will be $y=\frac{\overline{a+x}^2-a^2}{2}=a^1x+\frac{3a^0x^2}{2}+ax^1+\frac{x^2}{4}$. But this fluent may be found without correction, by expanding $\overline{a+x}^2$ in the original equation, which will become $y=a^1x+2a^0x\dot{x}+2x^1x+x^2\dot{x}$, whence $y=a^1x+\frac{2a^0x^2}{2}+ax^1+\frac{x^2}{4}$. 3. Let $\dot{y}=\overline{a^2-x^2}^{\frac{1}{2}}\times x\dot{x}$; then $y=-\frac{\overline{a^2-x^2}^{\frac{3}{2}}}{3}$, and y being $=o$, $-\frac{\overline{a^2-x^2}^{\frac{3}{2}}}{3}$ becomes $=-\frac{a^3}{3}$; therefore $-\frac{\overline{a^2-x^2}^{\frac{3}{2}}}{3}$ is too little by $\frac{a^3}{3}$; and the fluent corrected will be $y=\frac{a^3}{3}-\frac{\overline{a^2-x^2}^{\frac{3}{2}}}{3}$, &c.

In the solution of other problems, the value of y will be equal

equal to nothing, when that of x is equal to any given quantity a. E. gr. Let $y = x^3$, and y is $= \frac{a^3}{3}$; but when $y = x$, $\frac{a^3}{3}$ is $= a^3$, by ſuppoſition; therefore the corrected fluent will be $y = \frac{x^3 - a^3}{3}$. 2. Let $y = -x^n$, then $y = -\frac{x^{n+1}}{n+1}$, which corrected becomes $y = \frac{a^{n+1} - x^{n+1}}{n+1}$, &c.

But if the propoſed *fluxion* were $\frac{a}{a-x}$, we cannot find its fluent by the rule above given; however, we may throw the *fluxion* into an infinite ſeries by dividing a by $a - x$ in the uſual method, and we ſhall find the quotient or $\frac{a}{a-x} = 1 + \frac{x}{a} + \frac{x^2}{a^2} + \frac{x^3}{a^3}$, &c. Hence $\frac{a}{a-x} = x + \frac{x^2}{2a} + \frac{x^3}{3a^2} + \frac{x^4}{4a^3}$, &c. Now the fluent of each term of this ſeries may be found by the foregoing rule; and therefore the fluent of $\frac{a}{a-x}$ will be expreſſed by the ſeries $x + \frac{x^2}{2a} + \frac{x^3}{3a^2} + \frac{x^4}{4a^3}$, &c. which may be of uſe for determining the fluent when x is very ſmall in reſpect of a; becauſe in that caſe, a few terms at the beginning of the ſeries will be nearly equal to the value of the whole. But it often happens that the ſeries deduced in this method converges ſo ſlowly, as to be of little or no uſe. Or, becauſe the *fluxion* of the hyperbolic logarithm of any quantity is equal to the *fluxion* of that quantity divided by the quantity itſelf, the fluent of $\frac{a}{a-x}$ will be $= a \times$ hyp. log. of $a - x$. For the *fluxion* of $a - x$ is $= -x$, which divided by $a - x$ is $\frac{x}{a-x}$. See Maclaurin's Treat. of Flux. art. 737. 744. 827. Sterling, De Summat. Series. p. 28. and Simpſon's Fluxions, vol. i. p. 87, &c. Mathematicians do not always immediately recur to infinite ſeries, when it does not appear that a fluent can be aſſigned in a finite number of algebraic terms. The arches of a circle, and hyperbolic areas or logarithms, cannot be aſſigned in algebraic terms, but have been computed with great exactneſs by ſeveral methods. By theſe with algebraic quantities, any ſegments of conic ſections, and the arches of a parabola, are eaſily meaſured; and when a fluent can be aſſigned by them, this is conſidered as the ſecond degree of reſolution. When it does not appear that a fluent can be meaſured by the areas of conic ſections, it may however be meaſured in ſome caſes by their arcs; and this may be conſidered as the third degree of reſolution. If it does not appear that a fluent can be aſſigned by the arc of any conic ſections (the circle included) it may however be of ſome uſe to aſſign the fluent by an area, or arc of ſome other figure, that is eaſily conſtructed or deſcribed; and it is often important, that the propoſed *fluxion* be reduced to a proper form, in order that the ſeries for the fluent may not be too complex, and that it may not converge at too ſlow a rate.

We may therefore conſtitute three orders or claſſes of fluents. Firſt, ſuch as can be accurately aſſigned in finite terms by common algebraic expreſſion. Secondly, thoſe which can be reduced to circular arcs and logarithms. Thirdly, ſuch as can be aſſigned by hyperbolic or elliptic arcs. The firſt two claſſes (conſidering triangles and circles as conic ſections) may therefore be meaſured by the areas of conic ſections; and the third claſs by their perimeters, or lines that bound them.

The fluent of $\frac{x}{\sqrt{1 \pm xx}}$ is of the firſt claſs; that of $\frac{x}{\sqrt{x \times \sqrt{1 \pm xx}}}$, or of $\frac{x}{\sqrt{1 \pm xx}}$, of the ſecond; but the fluents of $\frac{xx}{\sqrt{1 \pm xx}}$, $\frac{x}{\sqrt{x \times \sqrt{1 \pm xx}}}$, $\frac{x}{1 \pm xx}$, and $\frac{x}{(1 \pm xx)^{\frac{3}{2}}}$ are of the third claſs, and as far as has appeared hitherto, cannot be reduced to the former. See Maclaurin's Fluxions, book ii. chap. iii. art. 755. 798, &c.

It is to be obſerved, as to the fluent of $\frac{x}{\sqrt{x \times \sqrt{1 \pm xx}}}$ or of $\frac{x}{1 - x^4}$, that it does not appear poſſible to repreſent them by any hyperbolic arc and algebraic quantities. But by aſſuming an ellipſe are likewiſe, they may be conſtructed. See Maclaurin, ib. cit. art. 802.

So likewiſe to repreſent the fluent of $\frac{x}{\sqrt{x \times \sqrt{b^2 \pm 2xx - xx}}}$ or of $\frac{x}{\sqrt{a^4 \pm 2aaxx - x^4}}$, we muſt have recourſe to both the hyperbolic and elliptic arcs. Maclaurin, ib. cit. art. 805.

$= \frac{rn}{4} - 1 \frac{c}{}$

The fluent of $\frac{x^n}{\sqrt{1 + x^n}}$ is aſſignable by the arcs of conic ſections, when r is an integer number; that is, by right lines, when r is equal to 4, or to any multiple of 4; by circular and parabolic arcs (reducible to logarithms) with right lines, when r is any other even number; by arcs of an equilateral hyperbola with right lines, when r is any number of the ſeries 3, 7, 11, 15, &c. and by arcs of the ſame hyperbola and right lines, with arcs of an ellipſis, that has its excentricity equal to the ſecond axis, when r is any of the numbers 1, 5, 9, 13, &c. See Maclaurin, ibid. art. 800.

We preſume, upon the whole, that few will be ſo ſcrupulous as to deny the Newtonian doctrine of *fluxions* to be intelligible, and accurately demonſtrated. But on the other hand it muſt be conſidered, that the introduction of the notions of motion and velocity, which are mechanical, ſeems not to have thrown any light on this part of geometry. The conſideration of the limiting ratios of variable quantities, and that of the limiting polygons of curves, as it requires no other knowledge but what depends on the common properties of number and magnitude, ſo it ſeems, in all reſpects, the moſt clear and unexceptionable manner of conſidering the ſubjects treated of in the higher geometry. An eminent mathematician ſeems to declare himſelf of this opinion, when he ſays, that quadrature by limiting polygons is one of that kind which requires no other knowledge but what depends on the common properties of number and magnitude; and ſo may ſerve as an inſtance to ſhew, that no other is requiſite for the eſtabliſhment of principles for arithmetic and geometry; a truth, which though certain in itſelf, may perhaps ſeem doubtful from the nature and tendency of the preſent enquiries in mathematics. For among the moderns ſome have thought it neceſſary, for the inveſtigation of the relations of quantities, to have recourſe to very hard hypotheſes; ſuch as that of numbers infinite, and indeterminate; and that of magnitudes in *ſtatu fieri*, exiſting in a potential manner, which are actually of no bigneſs. And others, whoſe names are truly to be reverenced, on account of their great and ſingular inventions, have thought it requiſite to have recourſe even to principles foreign to mathematics, and have introduced the conſideration of efficient cauſes and phyſical powers, for the production of mathematical quantities; and have ſpoken of them, and uſed them, as if they were a ſpecies of quantities by themſelves. Vide Machin, in Phil. Tranſ. N° 447.

The elements of the doctrine of *fluxions* have been delivered by its great author in ſo conciſe a manner, as to give occaſion to one of the moſt ingenious writers of this age to repreſent it as founded on inconceivable principles, and full of falſe reaſonings. This author, in a letter, under the title of the Analyſt, publiſhed in the year 1734, has been at great pains to convince his readers, that the objects, principles, and inferences of the modern analyſis by *fluxions*, are not more diſtinctly conceived, or more evidently deduced, than religious myſteries and points of faith. He ſays he does not controverſe the truth of the concluſions, but only the logic and method of mathematicians. He aſks how they demonſtrate, what objects they are converſant with, and whether they conceive them clearly; what principles they proceed upon, how found they may be, and how they apply them; declaring himſelf not concerned about the truth of the theorems, but only about the way of coming at them, whether it be legitimate or illegitimate, clear or obſcure, ſcientific or tentative. He conſiders the concluſions not in themſelves, but in their premiſes; not as true or falſe, uſeful or inſignificant, but as derived from ſuch principles, and by ſuch inferences. And for as much as it may ſeem an unaccountable paradox, that mathematicians ſhould deduce true propoſitions from falſe principles, be right in the concluſion, and yet err in the premiſes, he endeavours particularly to explain, how this may come to paſs, and how how error may bring forth truth, though it cannot bring forth ſcience. His ſolution of the paradox is, that in the application of the method of infiniteſimals and *fluxions*, two errors are committed, which being equal and contrary, deſtroy each other. We cannot enter into a detail of all he ſays on theſe and many other heads, nor of all that has been ſaid on the other ſide, in defence of the method of

fluxions, and of its inventor, Sir Isaac Newton. An anſwer to the Analyſt, under the title of Geometry no Friend to Infidelity, appeared very early under the name of Philalethes Cantabrigienſis, ſuppoſed to be Dr. Jurin; a ſecond, by the ſame hand, in defence of the firſt, intitled, The Minute Mathematician, or the Free-thinker no juſt Thinker, publiſhed in 1735; a Diſcourſe of *Fluxions*, by Mr. Robins, firſt publiſhed in 1735 (ſee his Collection of Tracts, by Wilſon, vol. ii.); a Treatiſe of Sir Iſaac Newton's with a Commentary by Mr. Colſon; and ſeveral other pieces were publiſhed on this ſubject; particularly a very full and excellent treatiſe of *fluxions*, by Mr. Maclaurin, late profeſſor of mathematics in the Univerſity of Edinburgh, containing not only a moſt diſtinct account of the principles of *fluxions*, but alſo of the chief diſcoveries in geometry, and mathematical philoſophy of this age. The curious may find an elegant account of this treatiſe in the Philoſophical Tranſactions, N° 468, 469.

We preſume that Mr. Maclaurin's demonſtrations are ſufficient to ſatisfy the moſt ſcrupulous; it would exceed the bounds of our deſign to inſert them at length here; but we cannot omit mentioning what ſeems neceſſary to explain and illuſtrate the notion of *fluxions*; and the principles on which this method of computation is founded.

In the doctrine of *fluxions*, magnitudes are conceived to be generated by motion; and the velocity of the generating motion is the *fluxion* of the magnitude. Lines are ſuppoſed to be generated by the motion of points; the velocity of the point that deſcribes the line, is its *fluxion*, and meaſures the rate of its increaſe or decreaſe. When the motion of a point is uniform, its velocity is conſtant, and is meaſured by the ſpace deſcribed by it in a given time: when the motion varies, the velocity at any term of the time is meaſured by the ſpace which would be deſcribed in a given time, if the motion was to be continued uniformly, from that term, without any variation. And this is analogous to the general doctrine of powers, or may be conſidered as a particular application of it. As a power which acts continually and uniformly is meaſured by the effect that is produced by it in a given time, ſo the velocity of an uniform motion is meaſured by the ſpace that is deſcribed in a given time. If the action of the power vary, then its exertion at any rate of the time is not meaſured by the effect that is produced after that term in a given time, but by the effect that would have been produced if its action had continued uniform from that term; and in the ſame manner, the velocity of a variable motion at any given term of time is not to be meaſured by the ſpace that is actually deſcribed after that term in a given time, but by the ſpace that would have been deſcribed, if the motion had continued uniformly from that term. If the action of a variable power, or the velocity of a variable motion, may not be meaſured in this manner, they muſt not be ſuſceptible of any menſuration at all. When it is ſuppoſed that a body has ſome velocity or other at any term of the time, during which it moves, it is not therefore ſuppoſed, that there can be any motion in a term, limit or moment of time, or in an indiviſible point of time; and as velocity is always meaſured by the ſpace that would be deſcribed by it, continued uniformly for ſome given finite time, it cannot ſurely be ſaid, that geometers pretend to conceive motion or velocity without regard to ſpace or time, as the author of the Analyſt often ſuggeſts. This is a ſhort view of the nature and tendency of the doctrine of *fluxions*, which we ſhall now proceed to explain more particularly.

We have already ſaid that lines may be conceived as generated by the motion of points; in like manner ſurfaces may be conceived as generated by the motion of lines; ſolids by the motion of ſurfaces; angles by the rotation of their ſides; the flux of time being ſuppoſed to be always uniform. The velocity with which a line flows, is the ſame as that of the point which is ſuppoſed to deſcribe or generate it. The velocity with which a ſurface flows, is the ſame as the velocity of a given right line; that, by moving parallel to itſelf, is ſuppoſed to generate a rectangle which is always equal to the ſurface. The velocity with which a ſolid flows, is the ſame as the velocity of a given plain ſurface, that, by moving parallel to itſelf, is ſuppoſed to generate an erect priſm or cylinder that is always equal to the ſolid. The velocity with which an angle flows, is meaſured by the velocity of a point, that is ſuppoſed to deſcribe the arch of a given circle, which always ſubtends the angle, and meaſures it. In general, all quantities of the ſame kind (when we conſider their magnitude only, and abſtract from their poſition, figure, and other affections) may be repreſented by right lines, that are ſuppoſed to be always in the ſame proportion to each other as theſe quantities. They are repreſented by right lines in this manner in Euclid's Elements, in the general doctrine of proportion, and by right lines and figures in the data of that accurate geometer. In this method likewiſe, quantities of the ſame kind may be repreſented by right lines, and the velocities of the motions by which they are ſuppoſed to be generated, by the velocities of points moving in right lines. All the velocities we have mentioned are meaſured, at any term of the time of the motion, by the ſpaces which would be deſcribed in a given time by theſe points, lines, or ſurfaces, with their motions continued uniformly from that term.

A *fluxion* being the velocity with which a quantity flows, at any term of the time while it is ſuppoſed to be generated, is therefore always meaſured by the increment or decrement that would be generated in a given time by this motion, if it was continued uniformly from that term without any acceleration or retardation; or it may be meaſured by the quantity that is generated in a given time by an uniform motion, which is equal to the generating motion at that term.

Time is repreſented by a right line that flows uniformly, or is deſcribed by an uniform motion; and a moment, or termination of time, is repreſented by a point or termination of that line. A given velocity is repreſented by a given line, the ſame which would be deſcribed by it in a given time. A velocity that is accelerated or retarded, is repreſented by a line that increaſes or decreaſes in the ſame proportion. The time of any motion being repreſented by the baſe of a figure, and any part of the time by the correſponding part of the baſe; if the ordinate at any point of the baſe be equal to the ſpace that would be deſcribed, in a given time, by the velocity at the correſponding term of the time continued uniformly, then any velocity will be repreſented by the correſponding ordinate. The *fluxions* of quantities are repreſented by the increments or decrements, deſcribed in the foregoing paragraph, which meaſure them; and inſtead of the proportion of the *fluxions* themſelves, we may always ſubſtitute the proportion of their meaſures.

When a motion is uniform, the ſpaces that are deſcribed by it in any equal times are always equal. When a motion is perpetually accelerated, the ſpaces deſcribed by it in any equal times that ſucceed after one another, perpetually increaſe. When a motion is perpetually retarded, the ſpaces that are deſcribed by it in any equal times that ſucceed after one another, perpetually decreaſe. It is manifeſt, converſely, that if the ſpaces deſcribed in any equal times are always equal, then the motion is uniform. If the ſpaces deſcribed in any equal times that ſucceed after one another perpetually increaſe, the motion is perpetually accelerated; for it is plain, that if the motion was uniform for any time, the ſpaces deſcribed in any equal parts of this time would be equal; and if it was retarded for any time, the ſpaces deſcribed in equal parts of this time that ſucceed after one another would decreaſe; both of which are againſt the ſuppoſition. In like manner it is evident, that a motion is perpetually retarded, when the ſpaces that are deſcribed in any equal times that ſucceed after one another, perpetually decreaſe. The following axioms are an evident, as that a greater or leſſer ſpace is deſcribed in a given time, according as the velocity of the motion is greater or leſs.

Axiom 1. The ſpace deſcribed by an accelerated motion is greater than the ſpace which would have been deſcribed in the ſame time, if the motion had not been accelerated, but had continued uniform from the beginning of the time.

Axiom 2. The ſpace deſcribed by a motion while it is accelerated, is leſs than the ſpace which is deſcribed in an equal time by the motion that is acquired by that acceleration continued uniformly.

Axiom 3. The ſpace deſcribed by a retarded motion is leſs than the ſpace which would have been deſcribed in the ſame time, if the motion had not been retarded, but had continued uniform from the beginning of the time.

Axiom 4. The ſpace deſcribed by a motion while it is retarded, is greater than the ſpace which is deſcribed in an equal time by the motion that remains after that retardation, continued uniformly.

From theſe axioms, general theorems concerning motion, of uſe in the doctrine of *fluxions*, may be demonſtrated. Thus when the ſpaces deſcribed by two variable motions are always equal, or in a given ratio, the velocities are always equal, or in the ſame given ratio; and converſely, when the velocities of two motions are always equal to each other, or in a given ratio, the ſpaces deſcribed by theſe motions in the ſame time are always equal, or in that given ratio; that when a ſpace is always equal to the ſum or difference of the ſpaces deſcribed by two other motions, the velocity of the firſt motion is always equal to the ſum or difference of the velocities of the other motions; and converſely, that when a velocity is always

always equal to the sum or difference of two other velocities, the space described by the first motion is always equal to the sum or difference of spaces described by these two other motions. See Mr Maclaurin's Treatise of Fluxions, book i. chap. 1.

The main point in the method of *fluxions*, is to obtain the *fluxion* of the rectangle, or product of two indeterminate quantities, since from thence may be derived rules for all other products and powers, be the coefficients, or the indices what they will; integers or fractions, rational or furd; according to the manner of Sir Isaac Newton, in the second lemma of his second book of Principles.

Mr. Maclaurin has therefore been very full in eſtabliſhing this point, and after what he has ſaid, we preſume that no reaſonable objection can lie either againſt the clearneſs and diſtinctneſs of the notion of *fluxions*, or againſt the truth of the principles, or accuracy of the demonſtrations by which their meaſures are determined. We cannot here inſert his demonſtration at length; but as many readers may, perhaps, be deſirous of ſeeing the argument contracted into a narrow compaſs, we ſhall here give a ſummary of it, from the Philoſophical Tranſactions, N° 468, p. 331, or Martyn's Abridg. vol. viii. p. 31, &c.

A triangle that has two of its ſides given in poſition, is ſuppoſed to be generated by an ordinate moving parallel to itſelf along the baſe. When the baſe increaſes uniformly, the triangle increaſes with an accelerated motion, becauſe its ſucceſſive increments are *inæquales*, that continually increaſe; therefore if the motion with which the triangle flows, was continued uniformly from any term for a given time, a leſs ſpace would be deſcribed by it, than the increment of the triangle, which is actually generated in that time by axiom 1. but a greater ſpace than the increment which was actually generated in an equal time preceding that term, by axiom 2. And hence it is demonſtrated, that the *fluxion* of the triangle is accurately meaſured by the rectangle contained by the correſponding ordinate of the triangle, and the right line which meaſures the *fluxion* of the baſe. The increment which the triangle acquires in any time, is reſolved into two parts; that which is generated in conſequence of the motion with which the triangle flows at the beginning of the time, and that which is generated in conſequence of the acceleration of this motion for the ſame time. The latter is juſtly neglected in meaſuring that motion (or the *fluxion* of the triangle at that term) but may ſerve for meaſuring its acceleration, or the ſecond *fluxion* of the triangle. The motion with which the triangle flows, is ſimilar to that of a body deſcending in free ſpaces by an uniform gravity, the velocity of which, at any term of the time, is not to be meaſured by the ſpace deſcribed by the body in a given time, either before or after that term, becauſe the motion continually increaſes, but by a mean between theſe ſpaces.

When the ſides of a rectangle increaſe or decreaſe with uniform motions, it may be always conſidered as the ſum or difference of a triangle and trapezium; and this *fluxion* is derived from the laſt propoſition. If the ſides increaſe with uniform motions, the rectangle increaſes with an accelerated motion; and in meaſuring this motion at any term of the time, a part of that increment of the rectangle that may be determined, is rejected, as generated in conſequence of the acceleration of that motion.

Thoſe who have well underſtood what precedes, will not be at a loſs to conceive, that the *fluxions* of a curvilineal area, whether generated by an ordinate moving parallel to itſelf, or by a radius revolving round a given centre, may be determined by demonſtrations of the ſame kind. When the ordinates of the figure increaſe, the increment of the area may be reſolved in like manner into two parts, one of which only is to be retained in meaſuring the *fluxion* of the area, the other being rejected as generated in conſequence of the acceleration of the motion with which the figure flows.

What has been hitherto ſaid will ſet the difference between the notion of *fluxions* and that of infiniteſimals, in a clear light. *Fluxions* may always be repreſented by finite quantities. The ſuppoſition of an infinitely little magnitude is too bold a poſtulatum for ſuch a ſcience as geometry. Nor have authors accounted explicitly for the truth and perfect accuracy of the concluſions derived from this conſideration. When they determine what is called the *difference*, but more accurately the *fluxion* of a quantity, they tell us they reject certain parts of the element, becauſe they become infinitely leſs than the other parts. But this is no proper reaſon, not only becauſe a proof of this nature may leave ſome doubt as to the accuracy of the concluſion, but becauſe it may be demonſtrated that theſe parts ought to be neglected by them at any rate, or that it would be an error to retain them. If an accountant, that preſends to a ſcrupulous exactneſs, ſhould tell us, he had neglected certain articles, becauſe he found them to be of ſmall importance; and it ſhould appear that they ought not to have been taken into conſideration by him on that occaſion, but belong to a different account, we ſhould approve his concluſions as accurate, but not his reaſons. See Maclaurin's Treatiſe of *Fluxions* in the preface, and book i. chap. 12. where the method of INFINITESIMALS is expreſly treated of.

Mr. Maclaurin, in the firſt part of his treatiſe conſiders *fluxions* in a merely geometrical form, and has demonſtrated the rules of the method with all poſſible accuracy and rigour; but as the great improvements made by this doctrine are chiefly to be aſcribed to the facility, conciſeneſs, and great extent of the methods of computation, or the algebraic part, it is neceſſary to add ſome account of theſe methods alſo.

Any quantities produced from each other by an algebraic operation, or whoſe relation is expreſſed by an algebraic form, being ſuppoſed to increaſe or decreaſe together, ſome will be found to increaſe or decreaſe by greater differences, or at a greater rate, others by leſs differences, or at a leſs rate; and while ſome are ſuppoſed to increaſe or decreaſe at one conſtant rate by equal ſucceſſive differences, others increaſe or decreaſe by differences that are always varying. Theſe rates of increaſe or decreaſe may be determined by comparing the velocities of points that always deſcribe lines proportional to the quantities as before mentioned, but they may alſo be determined without having recourſe to ſuch ſuppoſitions, by a juſt reaſoning from the ſimultaneous increments or decrements themſelves.

When a quantity A increaſes by differences equal to a, 2 A increaſes by differences equal to 2 a, and manifeſtly increaſes or decreaſes at a greater rate than A in the proportion of 2 a to a or 2 to 1; and if m and n be invariable, $\frac{m}{n}$ A increaſes or decreaſes by differences equal to $\frac{m}{n}a$, and therefore at a greater or leſs rate than A in proportion as $\frac{m}{n}$ is greater or leſs than a, or m is greater or leſs than n. This ſeems to be eaſily conceived, without having recourſe to any other conſiderations, than the relation of the differences by which the quantities increaſe or decreaſe. In order therefore to avoid figurative expreſſions in the algebraic part, it will be proper to ſubſtitute in the place of this definition and axioms before mentioned, others that are rather of a more general import, but are perfectly conſiſtent with them. Thus,

Fluxions *of quantities are any meaſures of their reſpective rates of increaſe or decreaſe while they vary or flow together.*

There can be no difficulty in determining thoſe meaſures when the quantities increaſe or decreaſe by ſucceſſive differences, that are always in the ſame invariable proportion to each other. While A by increaſing becomes equal to A + a, or by decreaſing equal to A − a, 2A becomes equal to 2 A + 2a, or to 2 A − 2a; and as 2 A increaſes or decreaſes at a greater rate than A in the proportion of 2a to a; ſo the *fluxion* of A being ſuppoſed equal to a, the *fluxion* of 2 A muſt be equal to 2 a. In the ſame manner the *fluxion* of $\frac{m}{n} \times$ A (or of $\frac{m}{n} \times$ A $\pm r$, ſuppoſing m, n, and r, to be invariable) is $\frac{m}{n} \times a$; and ſince m may be to n in any aſſignable ratio, a quantity may be always aſſigned that ſhall increaſe or decreaſe, at a greater or leſs rate than A in any proportion, or that ſhall have its *fluxion* greater or leſs than the *fluxion* of A in any ratio. In ſuch caſes, the ratio of the *fluxions* and that of the differences, by which the quantities increaſe or decreaſe, are the ſame.

But while A is ſuppoſed to increaſe at a conſtant rate by any equal ſucceſſive differences, if B increaſe or decreaſe by differences that are always varying, B cannot be ſaid to increaſe or decreaſe at any one conſtant rate; and it is not ſo obvious how, the *fluxion* of A being ſuppoſed equal to its increment a, the variable *fluxion* of B is to be determined. It cannot be ſuppoſed that the *fluxions* and differences are always in the ſame proportion in this caſe; but it is evident, that if B increaſe by differences that are always greater than the equal ſucceſſive differences by which $\frac{m}{n} \times$ A increaſes, it cannot increaſe at a leſs rate than $\frac{m}{n} \times$ A; and it cannot increaſe at a greater rate than $\frac{m}{n} \times$ A, while its ſucceſſive differences

are

always less than those of $\frac{m}{n} \times A$. The *fluxion* of A, being still represented by a, the *fluxion* of B therefore cannot be less than $\frac{m}{n} \times a$ in the former case, or greater than $\frac{m}{n} \times a$ in the latter. The following propositions are consequences of this, and will enable us to determine at what rate B increases, when its relation to A is known.

The succeſſive values of the root A being represented by $A-a$, A, $A+a$, &c. which increase by any conſtant difference a, let the correſponding values of any quantity produced from A, by any algebraic operation, (or that has a dependence upon it ſo as to vary with it) be $B-b$, B, $B+\beta$, &c. Then, if the ſucceſſive differences b, β, &c. of the latter quantity always increaſe, how ſmall ſoever a may be, then B cannot be ſaid to increaſe at ſo great a rate as a quantity that increaſes uniformly by equal ſucceſſive differences greater than β, or at ſo ſmall a rate as any quantity that increaſes uniformly by equal ſucceſſive differences leſs than b. In like manner, if the relation of the quantities is ſuch, that the ſucceſſive differences b, β, &c. continually decreaſe; then B cannot be ſaid to increaſe at the ſame rate as a quantity that increaſes uniformly by equal ſucceſſive differences greater than b, or leſs than β.

Therefore the *fluxion* of A being ſuppoſed equal to the increment a, the *fluxion* of B cannot be greater than β or leſs than b, when the ſucceſſive differences b, β, &c. continually increaſe; and cannot be greater than b or leſs than β, when theſe ſucceſſive differences always decreaſe.

In the ſame manner, if the latter quantity decreaſe while the former increaſes, and its ſucceſſive values be $B+b$, $B-b$, &c then if the decrements b, b, &c. continually increaſe, B cannot be ſaid to decreaſe at ſo great a rate as a quantity that decreaſes uniformly by equal ſucceſſive differences greater than b, or at ſo ſmall a rate as a quantity that decreaſes uniformly by equal ſucceſſive differences leſs than β. Therefore in this caſe the *fluxion* of A being ſuppoſed equal to a, the *fluxion* of B cannot be greater than b or leſs than β. And in the ſame manner if the ſucceſſive decrements b, b, &c. always decreaſe, the *fluxion* of B cannot be greater than β, or leſs than b. Vide Maclaurin's Flux. book ii. chap. 1. tom. ii. p. 579 ſeq.

As the *fluxions* of quantities are any meaſures of the reſpective rates, according to which they increaſe or decreaſe; ſo it is of no importance how great or ſmall thoſe meaſures are, if they be in the juſt proportion or relation to each other. Therefore if the *fluxions* of A and B may be ſuppoſed equal to a and b reſpectively, they may be likewiſe ſuppoſed equal to $\frac{1}{2}a$ and $\frac{1}{2}b$, or to $\frac{ma}{n}$ and $\frac{mb}{n}$.

Prop. I. *The* fluxion *of the root* A *being ſuppoſed equal to* a, *the* fluxion *of the ſquare* A^2 *will be equal to* $2Aa$.

To demonſtrate this, let the ſucceſſive values of the root be $A-u$, A, $A+a$, and the correſponding values of the ſquare will be $A^2-2Au+u^2$, A^2, $A^2+2Aa+a^2$, which increaſe by the differences $2Au-u^2$, $2Aa+a^2$, &c. and becauſe thoſe differences increaſe, it follows from what has been ſaid, that if the *fluxion* of A be repreſented by a, the *fluxion* of A^2 cannot be repreſented by a quantity that is greater than $2Au+u^2$, or leſs than $2Au-u^2$. This being premiſed, ſuppoſe, as in the propoſition, that the *fluxion* of A is equal to a; and if the *fluxion* of A^2 be not equal to $2Aa$, let it firſt be greater than $2Aa$ in any ratio, as that of $2A+o$ to $2A$, and conſequently equal to $2Aa+oa$. Suppoſe now that u is any increment of A leſs than o; and becauſe a is to u as $2A+o$ is to $2Au+ou$, it follows, that if the *fluxion* of A ſhould be repreſented by u, the *fluxion* of A^2 would be repreſented by $2Au+ou$, which is greater than $2Au+ou$. But it has been ſhewn, that if the *fluxion* of A be repreſented by u, the *fluxion* of A^2 cannot be repreſented by a quantity greater than $2Au+u^2$. And theſe being contradictory, it follows, that the *fluxion* of A being equal to a, the *fluxion* of A^2 cannot be greater than $2Aa$. If the *fluxion* of A^2 can be leſs than $2Aa$, when the *fluxion* of A is ſuppoſed equal to a, let it be leſs in any ratio of $2A-o$ to $2A$, and therefore equal to $2Aa-oa$. Then becauſe a is to u as $2A-o$ is to $2Au-ou$, which is leſs than $2Au-u^2$, (a being ſuppoſed leſs than o, as before) it follows, that if the *fluxion* of A was repreſented by u, the *fluxion* of A^2 would be repreſented by a quantity leſs than $2Au-u^2$, againſt what has been ſhewn. Therefore the *fluxion* of A being ſuppoſed equal to a, the *fluxion* of A^2 muſt be equal to $2Aa$.

The *fluxions* of A and B being ſuppoſed equal to a and b, reſpectively, the *fluxion* of $A+B$ will be $a+b$, the *fluxion* of $A+B^2$, or of $AA+2AB+BB$, will be $2 \times A+B \times a+b$, or $2Aa+2Ba+2Bb+2Ab$, by the laſt article. The *fluxion* of $AA+BB$ is $2Aa+2Bb$, by the ſame; conſequently the *fluxion* of $2AB$ is $2Ba+2Ab$; and the *fluxion* of AB is $Ba+Ab$. Hence if P be equal to AB, and the *fluxion* of P be p, then p will be equal to $Ba+Ab$, and dividing by P, or AB, we find $\frac{p}{P} = \frac{a}{A} + \frac{b}{B}$. If $Q = \frac{A}{B}$, and q be the *fluxion* of Q, then $QB = A$, $\frac{q}{Q} + \frac{b}{B} = \frac{a}{A}$, or $\frac{q}{Q} = \frac{a}{A} - \frac{b}{B}$; and conſequently $q = \frac{Qa}{A} - \frac{Qb}{B} = \frac{a}{B} - \frac{Ab}{BB}$, or $\frac{aB-Ab}{BB}$.

When any of the quantities decreaſe, its *fluxion* is to be conſidered as negative.

The rule for finding the *fluxion* of a power is uſually deduced from the binomial theorem of ſir Iſaac Newton. But as this theorem, though eaſily found by induction, is not ſo eaſy to be demonſtrated, it is proper to proceed upon a principle, the truth of which may be ſhewn from the firſt algebraic elements, with more facility and perſpicuity. This principle is, that if n be any integer number, and the ſum of the terms E^{n-1}, $E^{n-2}F$, $E^{n-3}F^2$, $E^{n-4}F^3$, &c. continued till their number be equal to n, be multiplied by $E-F$, the product will be E^n-F^n. For the terms being formed by ſubſtituting continually unity from the index of E, and adding it to the index of F, the laſt term will be F^{n-1}. The product of the ſum of the terms multiplied by E will be $E^n+E^{n-1}F+E^{n-2}F^2+\ldots\ldots+E^2F^{n-2}$; their ſum multiplied by $-F$ gives $-E^{n-1}F-E^{n-2}F^2-\ldots-E^2F^{n-2}-EF^{n-1}-F^n$; and the ſum of theſe two products is E^n-F^n. Suppoſing E to be greater than F, $E-F$ will be leſs than $nE^{n-1} \times E-F$, but greater than $nF^{n-1} \times E-F$. For each of the terms E^{n-1}, $E^{n-2}F$, $E^{n-3}F^2$, is greater than the ſubſequent term in the ſame ratio that E is greater than F, and E^{n-1} is the greateſt term; conſequently the number of terms being equal to n, nE^{n-1} is greater than their ſum; and $nE^{n-1} \times E-F$ is greater than their ſum multiplied by $E-F$, or (by the laſt paragraph) greater than E^n-F^n. Becauſe the laſt term F^{n-1} is leſs than any preceding term, $nF^{n-1} \times E-F$ is leſs than the ſum of the terms multiplied by $E-F$, or leſs than E^n-F^n.

When n is any integer poſitive number, the root A being ſuppoſed to increaſe by any equal ſucceſſive differences, the ſucceſſive differences of the power A^n will continually increaſe. For let $A-a$, A, $A+a$, be any ſucceſſive values of the root, and $\overline{A-a}^n$, A^n, $\overline{A+a}^n$ will be the correſponding values of the power. But $\overline{A+a}^n - A^n$ is greater than $nA^{n-1}a$; as appears by ſubſtituting in the laſt paragraph $A+a$ for E, A for F, and a for $E-F$. In like manner, $nA^{n-1}a$ is greater than $A^n - \overline{A-a}^n$. Therefore $\overline{A+a}^n - A^n$ is greater than $A^n - \overline{A-a}^n$, and the ſucceſſive differences of the power continually increaſe.

Prop. II. *The* fluxion *of the root* A *being ſuppoſed equal to* a, *the* fluxion *of the power* A^n *will be* nAA^{n-1}.

For if the *fluxion* of A^n can be greater that nAA^{n-1}, let the exceſs be equal to any quantity r; ſuppoſe o equal to $\frac{r}{nA^{n-1}}$, the exceſs of $\sqrt{A^{n-1} + \frac{r}{nA}}$ above A, and conſequently $\overline{A+o}^{n-1} = A^{n-1} + \frac{r}{nA}$. Then $nA \times A + o^{n-1}$ will be equal to $nAA^{n-1} + r$, the *fluxion* of A^n. Let u be any increment of A leſs than o; and becauſe a is to u as $nA \times A+o^{n-1}$ is to $nAu \times A+o^{n-1}$, it follows (from what has been ſaid) that if the *fluxion* of A be now repreſented by the increment u, the *fluxion* of A^n will be repreſented by $nAu \times A+o^{n-1}$, which is greater than $nAu \times A+u^{n-1}$, and this laſt is itſelf greater than $A+u^n-A^n$. But when the ſucceſſive values of the root are $A-u$, A, $A+u$, thoſe of the power are $A-u^n$, A^n, $A+u^n$, the ſucceſſive differences of which continually increaſe; conſequently if the *fluxion* of A be repreſented by u, the *fluxion* of A^n cannot be repreſented by a quantity greater than $A+u^n-A^n$, or leſs than A^n-A-u^n. And theſe being contradictory, it follows, that when the *fluxion* of A is ſuppoſed equal to a, the *fluxion* of A^n cannot be greater than nAA^{n-1}. If it can be leſs than nAA^{n-1}, let it be equal to $nAA^{n-1}-r$, or (by ſuppoſing $r = A - o^{n-1}$

$\sqrt{A^{n-1} - \frac{r}{nA}}$) to $nA \times \overline{A-o}^{n-1}$. Then u being ſup-

poſed

posed less than n, if the *fluxion* of A was represented by $\dot{a}$, the *fluxion* of A^n would be represented by $n\dot{a} \times A^{n-1}$, which is less than $n\dot{a} \times A^{n-1}$ (because we suppose a to be less than a) and therefore less than $A^n = A^{n-1}a$. But this is repugnant to what has been demonstrated. Therefore the *fluxion* of A being supposed equal to $\dot{a}$, the *fluxion* of A^n must be equal to $n\dot{a}\,A^{n-1}$. Prop. III. The fluxion *of* $A^{\frac{m}{n}}$ *being supposed equal to* $\dot{a}$, *the* fluxion *of* $A^{\frac{m}{n}}$ *will be* $\frac{m\dot{a}}{n} \times A^{\frac{m}{n}-1}$.

First, let the exponent $\frac{m}{n}$ be any positive fraction whatsoever, suppose $A^{\frac{m}{n}} = K$; consequently $A^m = K^n$; and the *fluxion* of K being supposed equal to $\dot{k}$, $ma\,A^{m-1} = n\dot{k}\,K^{n-1}$, and $\dot{k}$ or the *fluxion* of $A^{\frac{m}{n}}$ will be equal to $\frac{ma\,A^{m-1}}{n\dot{k}\,K^{n-1}} = \frac{ma\,K}{n\dot{a}\,A^m} = \frac{m}{n} \times a\,A^{\frac{m}{n}-1}$. When $\frac{n}{m}$ is negative, let it be equal to $-r$; and suppose $A^{-r} = K$, or $I = A^r K$, then taking the *fluxions*, $rA^{r-1}a\dot{K} + \dot{a}A^r = 0$, and $\dot{k} = -\frac{rA^{r-1}a\dot{K}}{A^r} = -rA^{-r-1}\dot{a} = \frac{m}{n} \times a^{\frac{m}{n}-1}$.

Prop. IV. *Supposing* P *to be the product of any factors,* A, B, C, D, E, &c. *and the* fluxions *of* P, A, B, C, &c. *respectively equal to* p, a, b, &c. *then will* $\frac{p}{P} = \frac{a}{A} + \frac{b}{B} + \frac{c}{C} + \frac{d}{D}$, &c.

Let Q be equal to the product of all the factors of P, the first A excepted, that is, suppose P = AQ. Suppose R equal to the product of all the factors, the first two, A and B, excepted; that is, let P = ABR, or Q = BR. In the same manner let R = CS, S = DT, and so on. Then the *fluxions* of Q, R, S, T, &c. being supposed respectively equal to q, r, s, t, &c. it follows that $\frac{p}{P} = \frac{a}{A} + \frac{q}{Q}$, (because $\frac{q}{Q} = \frac{b}{B} + \frac{r}{R}$) $\frac{a}{A} + \frac{b}{B} + \frac{r}{R}$ = (because $\frac{r}{R} = \frac{c}{C} + \frac{s}{S}$) $\frac{a}{A} + \frac{b}{B} + \frac{c}{C} + \frac{s}{S}$ = (because $\frac{s}{S} = \frac{d}{D} + \frac{t}{T}$) $\frac{a}{A} + \frac{b}{B} + \frac{c}{C} + \frac{d}{D} + \frac{t}{T}$, and so on. Therefore $\frac{p}{P}$ is equal to the sum of the quotients, when the *fluxion* of each factor is divided by the factor itself.

If the factors be supposed equal to each other, and their number be equal to n, then $P = A^n$, and by the last proposition $\frac{p}{P} = \frac{na}{A}$; consequently $p = \frac{nPa}{A} = na\,A^{n-1}$, as was before demonstrated.

Prop. V. *If* $P = \frac{ABC}{KLM}$, &c. *and the* fluxions *of the respective quantities be expressed by the small letters* p, a, b, c, &c. *as before, then* $\frac{p}{P} = \frac{a}{A} + \frac{b}{B} + \frac{c}{C} - \frac{d}{K} - \frac{l}{L} - \frac{m}{M}$, &c.

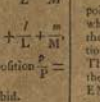
For PKLM, &c. = ABC, &c. and $\frac{p}{P} + \frac{k}{K} + \frac{l}{L} + \frac{m}{M}$, &c. $= \frac{a}{A} + \frac{b}{B} + \frac{c}{C}$, &c. whence by transposition $\frac{p}{P} = \frac{a}{A} + \frac{b}{B} + \frac{c}{C} - \frac{k}{K} - \frac{l}{L}$, &c. Maclaurin, ibid.

The notation we have hitherto used is the same as sir Isaac Newton's, in the second lemma of the second book of his Principles. But it is generally more convenient to distinguish *fluxions* from other algebraic expressions, and in such manner, that the second and higher *fluxions* may be represented so as to preserve the original fluent in view. Hence sir Isaac Newton, in his last method, represented variable or flowing qualities by the final letters of the alphabet, as x, y, z; their first, second, &c. *fluxions*, respectively by $\dot{x}$, $\dot{y}$, $\dot{z}$, and $\ddot{x}$, $\ddot{y}$, $\ddot{z}$, &c. But as this doctrine has been contested and represented by the author of the Analyst, as inconceivable and sophistical, we thought it proper more fully to explain and demonstrate the principles thereof, from Mr. Maclaurin's excellent treatise on this subject.

It is to be observed, that the *fluxions* of powers are commonly delivered in an algebraic form; but this is not necessary. The same may be done geometrically, by supposing a series of lines in geometric progression, the first term of which is invariable. Then if the second term be supposed to increase uniformly, all the subsequent terms will increase with an accelerated motion. The velocities of the points that describe those lines being compared, it may be demonstrated from common geometry, that the *fluxions* of any two terms are in a ratio compounded of the ratio of those terms, and of the ratio of the numbers that express how many terms precede them respectively, in the progression. Thus, if A, B, C, D, E, &c. represent any lines in geometrical progression, the first term (A) of which is invariable, then will the *fluxion*, for instance, of E be to the *fluxion* of D as 4 E is to 3 D, and the *fluxion* of E will be to the *fluxion* of B, as 4 E to B. The analogy between powers in algebra and lines in geometric progression, is sufficiently known. Thus A being invariable may be called unity or 1; let $B = x$, then will $C = x^2$, $D = x^3$, $E = x^4$, &c. and consequently, the *fluxion* of E or x^4, will be to the *fluxion* of B or x, as $4x^3$ is to x, or as $4x^2$ is to 1. Therefore if the *fluxion* of x be expressed by $\dot{x}$, the *fluxion* of x^4 will be expressed by $4x^3\dot{x}$, agreeable to the common algebraic method of expression. Vide Mr. Maclaurin's *Flux.* book i. chap. 6. See also the Present State of the Rep. of Let. Oct. 1735. p. 248, 249, &c.

If the *fluxion* of B, or the second term of the progression be invariable, every term of the progression will have *fluxions* of as many degrees, as there are terms that precede it in the progression. And the increment of any term generated in a given time may be resolved into as many parts, as it has *fluxions* of different orders; and each part may be conceived to be generated, in consequence of its respective *fluxion*. Hence *fluxions* of all orders may be illustrated and measured.

As to the higher orders of *fluxions*, it is to be observed, that when a motion is accelerated or retarded continually, the velocity may itself be considered as a variable or flowing quantity, and may be represented by a line that increases or decreases continually. When a velocity increases uniformly so as to acquire equal increments in equal times, its *fluxion* is measured by the increment which is generated in any given time. In this case, the velocity is represented by a line that is described by an uniform motion; and its *fluxion*, by the constant velocity of the point that describes the line, or by the space which this point describes in a given time. When a velocity is not accelerated uniformly, but acquires increments in equal times, that continually increase or decrease, then its *fluxion* at any term of the time is not measured by the increment, which it actually acquires, but by that which it would have acquired, if its acceleration had been continued uniformly from that term for a given time. And in the same manner, when a motion is retarded continually, the quantity by which it would be diminished in a given time, if this retardation was continued uniformly for any term, measures its *fluxion* at that term. While the point M describes the line E e, let the point Q describe the line I i, so that I Q may be always equal to the space that would be described by the motion of M, if it was continued uniformly for a given time. Then I Q shall always represent the velocity of M, and the velocity of the



point Q shall represent the *fluxion* of the velocity of M; which therefore is measured, at any term of the time by the space which would be described by Q, with its motion at that term continued uniformly for a given time. The velocity of M is the *fluxion* of E M; and therefore the velocity of Q represents the *fluxion* of the *fluxion* of E M. See the beginning of this article. Thus, when a *fluxion* of a quantity is variable, it may be considered itself as a fluent, and may have its *fluxion*, which is called the *second fluxion* of that quantity. This may also have its *fluxion*, which is called the *third fluxion* of the first fluent; and motions may be easily conceived to vary in such a manner, as to give ground for admitting second *fluxions*, and those of any higher order. And as the first *fluxion* of a variable quantity, at any term of the time, is measured by the increment, or decrement, which would be produced, if the generating motion was continued uniformly from that term, for a given time; so its second *fluxion* may be measured by twice the difference betwixt this increment, or decrement, and that which would be produced, if the acceleration, or retardation, of the generating motion was continued uniformly from that term for the same time. Maclaurin, lib. cit. book i. chap. 1. § 70. 75. and chap. 5. 6.

See a farther illustration of second and third *fluxions*, in the same author (chap. 3. and 4.) deduced from the consideration of the *fluxions* of solids.

The author of the Analyst has represented the notions of second and third *fluxions*, as inextricable mysteries; and

indeed, when ſome ſpeak of the velocities of velocities, &c. it is not eaſy to ſay what they mean. But it is to be obſerved, that the firſt *fluxion* of any fluent is not the velocity of that fluent, but the velocity of the motion by which the fluent is conceived to be generated. And in like manner, the ſecond *fluxion* of that fluent is not the velocity of the velocity of this fluent, but the velocity of the motion by which the quantity is generated that always repreſents its firſt *fluxion*, and ſo of the reſt.

When the *fluxion* of a quantity is variable it may be conſidered as a fluent; and its *fluxion*, which is the ſecond *fluxion* of the propoſed quantity, may be determined by the preceding propoſitions. Thus the *fluxion* of A being ſuppoſed equal to a, the *fluxion* of AA is $2Aa$; and if A be ſuppoſed to increaſe at an uniform rate, or its *fluxion* a to be invariable, $2Aa$ will increaſe by equal ſucceſſive differences; conſequently its *fluxion*, or the ſecond *fluxion* of AA, will be equal to any of theſe differences, as to $2a \times A + a - 2Aa$, or $2aa$. If a be variable, let its *fluxion* be equal to z, and the *fluxion* of $2Aa$ (or ſecond *fluxion* of AA) will be $2az + 2Az$. In the ſame manner the *fluxion* of A being conſtant, the *fluxion* of $nA^{n-1}a$, or the ſecond *fluxion* of A^n is $na \times \overline{n-1} \times A^{n-2}a$, or $n \times \overline{n-1} \times aaA^{n-2}$; the *fluxion* of this, or third *fluxion* of A^n, is $n \times n-1 \times n-2 \times a^3 A^{n-3}$. And the *fluxion* of A^n of any order denoted by m, is $n \times \overline{n-1} \times \overline{n-2} \times \overline{n-3}$, &c. $\times a^m A^{n-m}$, where the factors in the coefficient are to be continued till their number be equal to m. When n is any integer poſitive number, the *fluxion* A^n, of the order n, is invariable and equal to $n \times n-1 \times n-2 \times n-3$, &c. $\times a^n$. The quantities that repreſent theſe *fluxions* of A^n depend on a, which repreſent the *fluxion* of A. When A remains of the ſame value, the firſt *fluxion* of A^n is greater or leſs in the ſame proportion, as a is ſuppoſed to be greater or leſs; the ſecond *fluxion* of A^n, is in the duplicate ratio of a; and its *fluxion* of the order m, is as a^m. If a be variable, but n the *fluxion* of a, or the ſecond *fluxion* of A, be conſtant, then the fourth *fluxion* of AA will be conſtant and equal to $6zz$; for we found, that the ſecond *fluxion* of AA was $2aa + 2Az$; the *fluxion* of which is $4az + 2az$, or $6az$; and the *fluxion* of this is $6zz$. In like manner, the ſixth *fluxion* of A^3 will be conſtant in this caſe, and equal to $90z3$.

The ſecond differences of any quantity B are the ſucceſſive differences of its firſt differences; and as the *fluxion* B increaſes when its ſucceſſive differences increaſe; ſo its ſecond *fluxion*, or its *fluxions* of any higher order increaſe, when its ſecond or higher differences increaſe. If we arrive at differences of any order that are conſtant, the *fluxion* of the ſame order is conſtant, and is expreſſed by that difference. Thus when A is ſuppoſed to increaſe by conſtant differences equal to a, and its *fluxion* is ſuppoſed equal to a, the ſecond difference of AA (or $A + a^2 - 2AA + A - a^2$) is $2aa$, which is likewiſe its ſecond *fluxion*; and the third difference of A^3 is $6a^3$, which is its third *fluxion*. When n is any integer and poſitive number, the *fluxion* of A^n of the order n is equal to the *fluxion* of any of its firſt differences of the order $n-2$, and ſo on. For the *fluxion* of $A + a^n - A^n$ (one of the firſt differences of A^n) of the order $n-1$ is $n \times \overline{n-1} \times n-2$, &c. $\times A + a^{n-n+1} - A \times a^{n-1} = n \times \overline{n-1} \times n-2$, &c. $\times a^n$, where the coefficients are ſuppoſed to be continued till their number be $n-1$, ſo that the laſt muſt be 2. And this we found to be the *fluxion* of A^n of the order n, in the preceding paragraph. In the ſame manner the *fluxion* of $A + a^n - 2A^n + A - a^n$ (the ſecond difference of A^n) of the order $n-2$, is equal to the *fluxion* of $A + a^n - A$ of the order $n-1$; and conſequently equal to the *fluxion* of A^n of the order n. Theſe *fluxions* are invariable and equal to the laſt or invariable differences. But in other caſes the *fluxions* of A^n of any order are leſs than its ſubſequent differences of the ſame order, but greater than the preceding differences, as before mentioned. Maclaurin's *Flux.* art. 720, ſeq.

By ſuppoſing one of the variable quantities to flow uniformly, it will have no ſecond or higher *fluxions*, and the higher *fluxions* depending on it will be expreſſed in a more ſimple manner. Thus the *fluxion* of x being ſuppoſed conſtant, the firſt *fluxion* of x^n being $nx^{n-1}z$, its ſecond *fluxion* will be $n \times \overline{n-1} \times x^{n-2}z^2$, and its *fluxion* of any order m will be $n \times \overline{n-1} \times n-2 \times n-3$, &c. $\times x^{n-m}z^m$, where the factors in the coefficient are to be continued till their number be equal to m.

The ſecond or higher *fluxions* of quantities may be found by particular theorems (without computing thoſe of the preceding orders) as may be ſeen by the laſt example. See farther in Maclaurin's *Fluxions*, art. 734. See Rule 10. in the beginning of this article.

The uſe of the direct method of *fluxions*, ſee ſpecified under the articles EVOLUTE, INFLECTION, MAXIMA and MINIMIS, and TANGENTS.

Thoſe of the inverſe method, ſee under QUADRATURE and RECTIFICATION *of curves*.

FLY. *Muſca*, in *Natural Hiſtory*. The account of the ſeveral ſpecies, genera, and claſſes of *flies*, is no ſmall part of the natural hiſtory of inſects. The number of the ſpecies of *flies* exceed perhaps even that of the butterfly; but the *flies* are in general ſmall, though there are ſome, as the ſibellæ, whoſe bodies are longer and larger than thoſe of the largeſt butterflies. The cicadæ alſo belong to the *fly* claſs; and there are ſome of thoſe, whoſe ſize exceeds that of the largeſt butterflies in the thickneſs of their bodies. The generality of *flies*, however, are much ſmaller than the butterfly claſs, and many of them are indeed ſo very ſmall, as not eaſily to be diſtinguiſhed.

Many of the *flies* are in their prior ſtate hid from us, or detained among very diſpleaſing matters; it is in their winged ſtate that they become an agreeable object of our reſearches, and it may be moſt proper, therefore, to begin their hiſtory in that ſtate, occaſionally deſcending to the others.

It is a common error to imagine, that the ſmall *flies* one ſees in the ſpring, will become larger in ſummer. This is wholly without foundation, ſince all the *flies*, like other inſects which undergo a metamorphoſis, become of their full bigneſs, as ſoon as they arrive at the *fly* ſtate, and never grow afterwards.

The general and obvious character of *flies*, by which they are diſtinguiſhed from other winged inſects, is their having tranſparent wings, and never having on them any of that powder which is found on the wings of butterflies, and having no caſes or covers for them. They are, by this plain character of their tranſparent and naked wings, diſtinguiſhed from the butterfly, the beetle, the graſſhopper, and other claſſes of winged inſects.

The parts of *flies* are the head, the CORCELET, and the body.

To the corcelet the wings are affixed, and in the body are contained the ſtomach, inteſtines, the parts of generation, and a great many of the tracheæ. The head in *flies* is uſually joined to the corcelet by a very ſhort neck, and can often turn on it as on a pivot. Some *flies* there are which have as it were two corcelets, one ſeparated from the other; the firſt in this caſe is uſually very ſmall, and the wings are affixed to the ſecond. The corcelet is the moſt prominent and rounded part of the inſect; it is always the ſtrongeſt part, and is frequently the thickeſt. The formica leo and ſome water inſects, are transformed into *flies* which have double corcelets, or corcelets divided into two.

The moſt obvious diſtinctions for the arrangement of *flies* into claſſes, is the number of their wings; ſome having only two, others four. And this is ſo plain and obvious a diviſion, that it is wonderful that the writers of natural hiſtory have not long ſince fallen into it, nay, many of them have often omitted to tell us the number of wings of the ſpecies they deſcribe.

The firſt general diviſion of *flies* is therefore into that of the two-winged and four-winged kinds. A very ſlight obſervation is generally ſufficient to determine to which of theſe diviſions a *fly* belongs; but if we afterwards examine a *fly* with more attention, and take into conſideration the organ by which it takes its nourihment, one may obſerve, that ſome of them are able to thruſt out that organ to a conſiderable diſtance from their head, and that this organ, which, while in a ſtate of reſt, is folded up or ſhortened, or turned about, or laid cloſely down, when the creature wants to uſe it, is unfolded, lengthened, extended, or raiſed. This organ is what naturaliſts call the trunk of an inſect, but there are many other *flies* which have no trunk; theſe have no other than an opening, ſerving for a mouth, ſurrounded with lips and with ſome other parts. This ſort of opening, from its ſituation and figure, may very properly be called a mouth.

Some of theſe mouths have nothing analogous to teeth about them; but there are others which have teeth, ſaws, or grinders, placed on the outſide of the mouth, and moveable as in the caterpillars, with which the *flies* tear and deſtroy leaves, fruits, and fleſh: finally, there are alſo ſome *flies* to which nature has allotted both a trunk and theſe organs.

Theſe characters give us very naturally the diſtinctions of four ſubordinate claſſes under the two former general ones.

The firſt contains thoſe *flies* which have a trunk, and no teeth or ſaws. The ſecond contains thoſe which have a mouth

mouth without any ſenſible teeth. The third, thoſe which have a mouth furniſhed with teeth; and the fourth, thoſe which have both trunks and teeth. Among the *flies* which have mouths furniſhed with teeth, ſome have them not only without, but within their mouths alſo.

All the two-winged *flies* belong to the firſt or ſecond of theſe claſſes; the great blue fleſh-*fly*, the ſmall *flies* that are ſo troubleſome about our houſes, and the gnats, are all of the firſt claſs, and have trunks and no teeth. The ſpring-*fly*, ſo common in gardens, and a ſort of *fly* reſembling the gnat kind, but much larger, are of the ſecond claſs, and have mouths, but no ſenſible teeth.

The four-winged *flies* furniſh us with great numbers to fill up the other two claſſes, left vacant by the former. All the bee-kind have a trunk and two teeth; all the waſp-kind have a mouth furniſhed with two teeth; and there are, beſide theſe, ſeveral of the four-winged *flies* which belong to the ſecond claſs; all the papilionaceous *flies*, produced of water-worms, are of this ſort, as having a mouth without teeth. Several ſmall four-winged *flies* are alſo of the firſt claſs; as the flying pucerons, and falſe pucerons, which have all trunks and no teeth: neither are the ſmaller ſpecies only of this claſs, ſince the cicadæ alſo belong to it.

A fifth claſs may, however, be alſo eſtabliſhed, though the ſpecies of it are only few, there being only two kinds of *flies* of it; this is, of thoſe which have their head ſerving the office, or made in the form of a trunk. The *flies* of this kind have very long heads, which, like thoſe of birds, terminate in a ſort of beak; this, however, in the *fly*-kind, is never opened except at the end: or, in other words, theſe *flies* have heads, which are lengthened out into the reſemblance of a bill, or figure of a trunk, but which is ſtiff, and cannot change its figure, nor alter its poſition, otherwiſe than by altering that of the whole head. At the end of this ſort of trunk are placed the teeth or other organs, by which the creature gets its food. The firſt example of theſe heads is in the ſcorpion-*fly*; and a very beautiful *fly*, that is frequently ſeen ſkipping and leaping about flowers, is the other.

Under theſe general claſſes, ſubordinate ones are to be formed, from whatever beſides is the moſt obvious and eſſential diſtinction among theſe little animals. The form of the body may very well afford us theſe diſtinctions. So that, in this reſpect, there are three ſubordinate claſſes under the five fore-mentioned claſſes: the firſt, of thoſe *flies* whoſe bodies are ſhort and broader than they are thick; the ſecond, of thoſe with long bodies; and the third, with bodies faſtened to the corcelet only by a fine filament: and under all theſe, the ſeveral genera are to be eſtabliſhed from other leſſer but conſtant and invariable differences; ſuch as the differences of the manner of their carrying their wings, the figures of their antennæ, the poſition of their trunks, and other ſimilar differences. See *Tab. of Inſects*, and WINGS, TRUNKS, *&c.*

FLIES, *bodies of*. The bodies of theſe inſects are extremely different one from another, and even thoſe whoſe general form makes them properly ranged in the ſame claſs, are not without their diſtinctions, by which they alone may be made to eſtabliſh ſubordinate genera.

Among the *flies* which have ſhort or elliptoide bodies, ſome have the body extremely flat and thin; ſuch are thoſe of the *flies* produced from the worms which devour the pucerons; and others have the hinder part of the body bent downward in form of a hook.

The extremity of the body in theſe animals is uſually ſmaller than the adjoining parts. Yet there is a *fly* found in the neſts of ſwallows, the extremity of whoſe body is larger than any other part of it; and not only the form of the body, but the differences of the filament, by which, in many genera, it is connected to the corcelet, may furniſh great matter for the diſtinctions of the ſubordinate genera.

The hinder part, or extremity of the body alone, may alſo afford great matter of diſtinction. Thoſe *flies* which carry ſtings in their tails, have in that alone a ſufficient diſtinction.

Others there are which have organs placed there, which though we need not fear them, offer ſubject enough for our admiration; it is indeed the females alone who have occaſion for theſe, and therefore the females alone are furniſhed with them.

Several of theſe inſtruments are a kind of auger or borer carried in a caſe or ſheath. This ſometimes has the form of a long tail to the inſect, and its uſe is to pierce and bore the body, in which the creature is to depoſit its eggs. Several of the female ichneumons have this ſort of long tail; and there are other inſects which have a long and ſtrong piercer, which however does not make a tail to their body, but is partly lodged either under their belly or in their body; of this kind are the cicadæ, and others.

Other inſects of this kind have a ſingular inſtrument lodged in this part of their body, which may properly be called a ſaw. They never ſhew this on examination, unleſs their bodies be preſſed, and then we cannot but greatly admire the inſtrument itſelf, and the powers by which the creature moves it.

Other inſects of this claſs carry behind one or more long ſlender filaments, which, in their form and ſtructure, have ſome ſort of reſemblance to the antennæ; and the uſes of which are as little known to us, as thoſe of the antennæ. The genera of *flies* may very properly be diſtinguiſhed by means of theſe: among the four-winged *flies*, the ephemerons, and many other ſpecies, have them; and among the two winged kinds, the ſmall *fly*, which is the male gall inſect, furniſhes us with an inſtance of them. See *Tab. of Inſects*.

FLIES *of water-worms*. Theſe, according to their ſeveral ſpecies, have ſome varieties in their manner of egreſs from their ſhell, at their leaving the nymph ſtate for that of the perfect *fly*.

The long water-worms, compoſed of many rings, and with funnel-faſhioned tails, made with an aperture for the admiſſion of the air, ſurrounded with a multitude of hairs, retain, in their ſhell-ſtate, ſo much of the ſame form which they had while living, that the one is not eaſy to be diſtinguiſhed from the other. The nymph in each of theſe fills up only a ſmall part of the cavity, and the *fly* in many of them is produced perfect in five or ſix days. At this time the parts of the nymph being thoroughly ſtrengthened, it begins to ſhew the firſt ſigns of life in its attempt to open its priſon.

To effect this, nature has ſo provided for the incloſed *fly*, that the head is but ſlightly joined to the ſecond ring of the body; but the creature in this ſtate, not being lodged in that part of the worm, can make no efforts againſt it; all its endeavours are bent to force a ſlit or opening in the ſecond ring, like that in the back of the ſkin of a caterpillar that is going to change its ſkin, or like that of the butterfly chryſalis. The means the incloſed *fly* uſes to this purpoſe, are the inflating and ſwelling its head, and then thruſting out the bladder from its anterior part, with which theſe *flies* are provided by nature in this ſtage of their lives, and for this only purpoſe. When this ſlit or crack is effected, the head of the worm is in ſome meaſure ſeparated from the body, and the efforts of the *fly* to puſh itſelf forward, finiſh that ſeparation, and leave an aperture of a proper ſize for the egreſs of the *fly*.

But the water, on the ſurface of which this change is effected, is a thing much to be dreaded, and indeed is often of fatal conſequences to the new-born *fly*, ſince the *flies* produced of water-worms are as much afraid of this element, and are as eaſily drowned, as thoſe produced from worms who ſpend their lives on dry land.

The *flies* produced from this long water-worm are, however, in leſs danger, and leſs afraid of the water than many others; they advance ſlowly out of their ſhells in an horizontal direction, and, as ſoon as their fore-feet are at liberty, they boldly place them upon the water, as if upon dry land, and it ſerves as well for their ſupport; and as their other parts get at liberty, they are gradually ſet upon the water too, and the creature there reſts till its wings are unfolded, and all its parts have their proper form, and then takes its flight into its new element.

The *fly* produced from this long worm is of the ſhort-bodied kind, and much of kin to the common great blue fleſh-*fly*. It has a fleſhy trunk furniſhed with lips, and has no teeth; but though this *fly* is ſo far of the ſame claſs with that common ſpecies, it has enough to amply diſtinguiſh it in theſe ſeparate characters. The firſt is, that this has its antennæ formed of granulated filaments, whereas the other has them of the baſtledore kind: the wings of the fleſh-*fly* are not croſſed upon the body, whereas thoſe of this water-*fly* are; but what more than theſe diſtinguiſhes it from this, and indeed from all the other ſpecies of *flies*, is, that it has two oblong and ſlender bodies formed like pins, and pointed as theſe, which are a little crooked, of a cruſtaceous ſtructure, and are inſerted in the upper part of the corcelet of the *fly*, and directed towards its hinder part. See *Tab. of Inſects*, N° 40.

Theſe prickles are hard, rigid, and immoveable.

FLY, *St. Mark*, in *Natural Hiſtory*, the name of a ſpecies of *fly*, which makes its firſt appearance every year about St. Mark's day, and is then ſeen in vaſt numbers; it is ſomewhat ſmaller than the large blue fleſh-*fly*, and has no trunk, but a mouth without teeth: notwithſtanding this ſeemingly innocent organization, the creature does great miſchief, and every gardener knows the effects of it at one time or other. Theſe *flies* are found about fruit trees, and are always ſeen ſiting upon the buttons of the leaves, and the flower-buds; and they do great miſchief

in many kinds of trees, by sucking the juices of those tender parts, and either destroying them before they open, or at least rendering them very weak. Some tell us that these *flies* had originally a sting, but that the mischief they did, being very great, St. Mark deprived them of that offensive weapon for all generations: this is a story much believed by the country people in many of the Roman catholic kingdoms. The mouth is of the same figure with that of the tipula, or long legs, being composed of two membranous lateral lips, like the two valves of a shell-fish, which defend and cover two other fleshy lips within.

The male is easily distinguished from the female, by having a much larger head, and reticular eyes much larger than her's, covering, in a manner, the whole head; besides these, it has also a cluster of three bright single eyes, placed in a triangle on the upper part of the head, and resembling the eyes of spiders. The wings of this *fly* are a little longer than its body, and crossed in such a manner, that one of them entirely covers the other, and even the body. This species has a singular manner of flying; they seem as if hanging in the air, their legs being suspended straight down from their body, and their length gives them an odd appearance. The common *flies* of this kind are of two species, one which is black, and another whose breast is a dusky red: but there are several other species so small as not to be distinctly seen without a microscope. They are all produced from worms, which are hatched from the eggs of the parent *fly*, deposited under the surface of the earth. They are found in great plenty in September and October in dung, into which they have crawled out of the earth for food.

If a piece of cow-dung, in which the worms of this St. Mark *fly* are, be preserved in a box, it will keep them alive the whole winter, and they will be found in the beginning of March, to be grown much larger than before and to be less hairy, their hairs being longer, and standing about nine on every ring. If this dung be laid on common earth at this time, they will crawl out of it into the ground, and transform themselves into the nymph state, from which they issue in the form of *flies* about the middle of April.

The manner of these *flies* leaving their worm state, to enter into that of the chrysalis or nymph, is worthy of observation. The worm seems in great disorder, and twists itself about several ways, till at length the skin; cracks on the surface of the back: immediately upon this, there appears the anterior part of the nymph at the aperture, and this forces its way out by degrees, the head becomes of no farther use, and is left with the skin; and the nymph, by distending and contracting itself, at length makes its way wholly out of it, and then remains at rest till the *fly* issues out of it. The last transformation of this insect, or the appearance of the *fly* from the nymph, has nothing singular in it, but is performed in the same manner, with the same change as in other animals of the same kind.

FLY, *fire*. See FIRE-*flies*.

FLY, *fishing*. See FISHING-*fly*.

FLY, *flower*, in *Natural History*, the name of a small but very beautiful *fly*, described by Clusius. It is black, and has two silvery wings, two white eyes, seven yellow spots on the back, and a black one in the middle.

FLY, *harvest*. See HARVEST.

FLY, *humble-bee*. See HUMBLE-BEE-*fly*, and CULEX.

FLY, *lantern*. See LANTERN-*fly*.

FLY, *rose*. See ROSE.

FLY, *scorpion*. See SCORPION-*fly*.

FLIES, *eggs of*. See EGGS.

FLIES, *eyes of*. See EYE.

FLIES, *legs of*. See LEG.

FLIES, *rings of*. See RINGS.

FLY, in *Mechanics*, a cross with leaden weights at its ends, or rather a heavy wheel at right angles to the axis of a heavy windlass or roller, by means of which the force of the power is not only preserved, but equally distributed in all the parts of the revolution.

The *fly* may be applied to several sorts of engines, whether moved by men, horses, wind, or water; and is of great use in those parts of an engine which have a quick circular motion, and where the power or resistance acts unequally in the different parts of a revolution. In this case the *fly* becomes a moderator, making the motion of revolution almost every where equal.

The force of a *fly*, when joined with the screw, for stamping the image upon coins, may be calculated thus: suppose its two arms to be each fifteen inches long, measuring from the centre of the weight to the axis of the motion, and the weights to be fifty pounds each, and the diameter of the axis pressing upon the dye to be one inch; if every stroke be made in half a second, and the weights describe an half circumference, which will in this case be of four feet, the velocity will at the instant of the stroke be at the rate of eight feet in a second, and therefore the momentum eight hundred; but the arms of the *fly* being as leavers, one brachium of which is fifteen inches long, whilst the other, viz. the semi-axis, is but half an inch, we must increase this force thirty times, which will give twenty-four thousand; an immense force, equal to that of a hundred pound weight falling a hundred and twenty feet, or near two seconds in time; or to that of a body of seven hundred and fifty pounds, falling 16 $\frac{1}{2}$ feet, or one second in time.

Some of these engines for coining crown-pieces have the arms of the *flies* five times as long, and the weights twice as heavy as those here mentioned, so that the effect is ten times greater. Desaguliers, Exper. Philosoph. vol. i. p. 245, 339.

FLY, in the *Sea-Language*, that part of the mariner's COMPASS on which the thirty-two winds are drawn, and to which the needle is fastened underneath.

FLY *of an ensign*, is the breadth or extent from the staff to the extremity or edge that flutters loose in the wind.

Let FLY *the sheets*, at *sea*, a word of command, in case of a gust of wind, lest the ship should overset, or spend her top sails and masts, to have the sheet go a-main, and then the sail will hold no wind.

FLY *the heels*, in the *Manage*. A horse is said to *fly* the HEELS, when he obeys the SPURS.

To FLY *grass*, in *Falconry*, is said of a hawk, when she flies at the great birds; as crane, greese, herons, &c.

FLY *on head*, is when the hawk, missing her quarry, betakes herself to the next check, as crows, &c. See HAWK.

FLY-*boat*, or *flight*, a large flat bottomed Dutch vessel, whose burthen is generally from four to six hundred tons. It is distinguished by a remarkably high stern, resembling a Gothic turret, and by very broad buttocks below.

FLY-*catcher*, *muscicapa*, in *Ornithology*, the name of a genus of PASSERES in the Linnæan system, including twenty-one different species; the characters of which are, that the bill is almost triangular, bent inwards at its beak, notched on both sides and beset with bristles, and that the nostrils are almost round. The birds of this genus found in Europe, are the *muscicapa grisola* and *atricapilla*. The former, or spotted *fly-catcher*, has a large head, of a brownish hue, spotted with black; the back is of a mouse colour, the wings and tail dusky; the interior edges of the quill-feathers are edged with pale yellow; the breast and belly are white; the throat and sides under the wings are dusked with red; the bill is broad at the base, and ridged in the middle; the inside of the mouth is yellow; the legs and feet are short and black. This is a bird of passage, appears with us in the spring, breeds here, and retires in August. It builds its nest on the side of trees towards the middle, and, according to Morton, in his History of Northamptonshire, in the corners of walls, where spiders weave their webs. They feed on flies and cherries.

The other is called the COLD-*finch*, and is a rare species with us. It is a small bird of the ficedula kind, and very nearly allied to the beccafigo, or petty-chaps. It is called also, in some places, *chacun* and *borin*. It is a little larger than the wren, and has a very sharp-pointed beak. Its head, neck, and back, are of a pale grey, and its throat and belly of a yellowish white. Its rump is white; its wing-grey; its tail, feet, and legs, are brown; and its claws very slender. Ray's Ornithology, p. 158.

FLY-*trees*, in *Natural history*, a name given by the common people in America to a tree, whose leaves, they say, at a certain time of the year, produce *flies*. On examining these leaves about the middle of summer, the time at which the flies used to be produced, there are found on them a sort of bags of a tough matter, of about the size of a filbert, and of a dusky greenish colour; on opening one of these bags with a knife, there is usually found a single full-grown *fly* of the gnat kind, and a number of small worms, which, in a day or two more, have wings, and fly away in the form of their parent. The tree is of the mulberry-kind, and its leaves are usually very largely flocked with these infected bags, and the generality of them are found to contain the insects in the worm state; when they become winged, they soon make their way out. The bags begin to appear when the leaves are young, and afterwards grow with them; but they never rumple the leaf, or injure its shape. They are of the kind of leaf galls, and partake in all respects, except size, of a species we have frequent on the large maple, or, as it is called, the sycamore. Philos. Trans. N° 431. See farther, Reaumur's Hist. vol. vi. p. 34. See PUCERON.

FLY-*worm*. See CAMPION.

FLYERS, in *Architecture*, such flights as go straight, and do not wind round, nor have the steps made tapering; but

but the fore and back-part of each ſtair, and the ends, reſpectively parallel to one another.

So that if one flight do not carry you to your deſigned height, there is a broad half ſpace; and then you fly again, with ſteps every-where of the ſame breadth and length as before.

FLYING, the progreſſive motion of a bird, or other winged animal, in the liquid air.

Flying is either *natural*, or *artificial*.

FLYING, *natural*, is that performed by an apparatus, or ſtructure of parts, concerted for that end by nature herſelf. Such is that of moſt birds and inſects, and of ſome fiſhes.

In Virginia and New-England they have monſtrouſly large *flying* beetles. Philoſoph. Tranſact. N° 127. And in Languedoc, graſſhoppers about an inch long, wherewith the ground, in ſeveral parts, in the year 1685, was covered one third of a foot deep. Ibid. N° 182.

The parts of bird, &c. chiefly concerned in *flying*, are the wings and tail: by the firſt the bird ſuſtains and wafts himſelf along; and by the ſecond, he is aſſiſted in aſcending and deſcending, to keep his body poiſed and upright, and to obviate the vacillations thereof.

It is by the largeneſs and ſtrength of the pectoral muſcles, that birds are ſo well diſpoſed for quick, ſtrong, and continued *flying*. Theſe muſcles, which in men are ſcarce a ſeventieth part of the muſcles of the body, in birds exceed and outweigh all the other muſcles taken together; upon which Mr. Willughby makes this reflection, that if it be poſſible for man to fly, his wings muſt be ſo contrived and adapted, that he may make uſe of his legs, and not his arms in managing them.

The *flying* of birds is thus effected:

The bird firſt bends his legs, and ſprings with a violent leap from the ground; then opens, or expands the joints of his wings, ſo as to make a right line, perpendicular to the ſides of his body: thus, as the wings, with the feathers therein, conſtitute one continued lamina, being now raiſed a little, and vibrating the wings, with great force and velocity, perpendicularly againſt the air, the air, though a fluid, reſiſts thoſe ſucceſſions, both from its naturalinactivity, and from its elaſticity, which makes it reſtore itſelf after it has been compreſſed, and re-act as much as it has been acted on: by ſuch means is the whole body of the bird protruded. The ſagacity of nature is very remarkable in the opening and recovering of the wing for freſh ſtrokes. To do it directly, and perpendicularly, it muſt needs have a great reſiſtance to overcome; to avoid which, the bony part, or bone, of the wing, into which the feathers are inſerted, moves ſideways, with its ſharp end foremoſt, the feathers following it like a flag.

The reſiſtance the air makes to the withdrawing of the wings, and, conſequently, the progreſs of the bird will be ſo much the greater, as the wall, or ſtroke, of the fan of the wing is the longer: but as the force of the wing is continually diminiſhed by this reſiſtance, when the two forces come to be in equilibrio, the bird will remain ſuſpended in the ſame place; for the bird only aſcends ſo long as the arch of air, the wing deſcribes, makes a reſiſtance equal to the exceſs of the ſpecific gravity of the bird above the air: if the air, therefore, be ſo rare as to give way with the ſame velocity as it is ſtruck withal, there will be no reſiſtance, and, conſequently, the bird can never mount.

Mr. Ray, Willughby, &c. have ſuppoſed the tail to do the office of a rudder, in ſteering and turning the body this way, or that; but Borelli has ſhewn it to be unfit for any ſuch office. The *flying* of a bird, in effect, is quite a different motion from the ſailing of a ſhip: birds do not vibrate their wings toward the tail, as oars are ſtruck towards the ſtern, but waft them downwards; nor does the tail of the bird cut the air at right angles, as the rudder does the water, but is diſpoſed horizontally, and preſerves the ſame ſituation, what way ſoever the bird turns.

In effect, as a veſſel in the water is turned about on its centre of gravity to the right, by a brisk application of the oars to the left, ſo a bird, in beating the air with its right wing alone, towards its tail, its fore-part will be turned to the left; as when in ſwimming, by only ſtriking out with the right arm and leg, we are driven to the left.

Add, that birds with long necks have another way of altering their courſe; for, by only inclining the head and neck towards this or that ſide, the centre of gravity of the whole being changed, the bird will proceed according to this new direction.

Birds never fly upwards in a perpendicular line, but always in a parabola, the line deſcribed by projectiles. In a direct aſcent, the natural and artificial tendency would oppoſe and deſtroy each other; ſo that the progreſs would be very ſlow. In a direct deſcent, they would fall one another, ſo that the fall would be too precipitate. Indeed the hawk, we frequently find, takes that advantage in ſeizing of the partridge: but ordinarily birds keep their wings expanded, and at reſt, to retard their deſcent; and at the ſame time ſtretch out their legs.

FLYING, *artificial*, is that attempted by men by the aſſiſtance of mechanics.

The *art of flying* is one of the great *deſiderata* of mechanics: it has been attempted in divers ages: the diſcovery of it might prove of great ſervice, and alſo of great diſſervice to mankind.

No body ſeems to have had ſo fair for that invention, as our famous friar Bacon, who lived upwards of five hundred years ago. He not only affirms the art feaſible, but aſſures us he himſelf knew how to make an engine, in which a man ſitting might be able to carry himſelf through the air like a bird; and affirms that there was another perſon who had actually tried it with ſucceſs.

The ſecret conſiſted in a couple of large thin hollow copper globes, exhauſted of air, which being much lighter than air, would ſuſtain a chair, whereon a perſon might ſit.

F. Franciſco Lana, in his *Prodromo*, propoſes the ſame thing, as his own thought. He computes that a round veſſel of plate-braſs, fourteen feet in diameter, weighing three ounces the ſquare foot, will only weigh 1828 ounces; whereas a quantity of air of the ſame bulk will weigh 2153 ounces; ſo that the globe will not only be ſuſtained in the air, but will carry with it a weight of 3735 ounces: and by increaſing the bulk of the globe, without increaſing the thickneſs of the metal, he adds, a veſſel might be made to carry a much greater weight.

But the fallacy is obvious; a globe of the dimenſions he deſcribes, Dr. Hook ſhews, would not ſuſtain the preſſure of the air, but would be cruſhed inwards. Therefore, in whatever *ratio* the bulk of the globe were increaſed, in the ſame muſt the thickneſs of the metal be alſo, and conſequently the weight increaſed: ſo that there would be no advantage in ſuch augmentation.

The ſame author deſcribes an engine for *flying*, invented by the ſieur Beſnier, a ſmith of Sable, in the county of Maine. Vide Philoſoph. Collect. N° 1.

The famous biſhop Wilkins was ſo confident of ſucceſs in this art, that he ſeems to intimate, that, in future ages, it will be as uſual to hear a man call for his wings when he is going a journey, as it is now to call for his boots. See Math. Magic, b. ii. ch. 7. Diſcovery of a new World, prob. xiv. p. 135. Secret and Swift Meſſenger, ch. iv.

FLYING *army* and *camp*. See CAMP.

FLYING *of colours*, is uſed by painters to denote their want of durableneſs, which they expreſs by their *ſtanding*.

FLYING-*fiſh*, a name given by the Engliſh writers to ſeveral ſpecies of fiſh, which by means of their long fins have a method of keeping themſelves out of water for ſome time. The *flying-fiſh*, moſt properly ſo called, is the exocetus, of the ancient authors, and of Artedi. See *Tab. IV. of Fiſh*, N° 41.

It is called alſo the *adonis*, *hirundo*, and *mugil alatus*, or winged mullet, by authors; but they uſe theſe words indeterminately for this and the other kinds.

In general ſize is about ſix inches in length: its head is covered with ſcales, and it reſembles the herring in the form of its body, but the back is flat. The ſcales are large and ſilvery; the diſtal fin is ſmall; its eyes are large; the mouth is ſmall, and is placed low in the head; and its jaws are granulated, rather than toothed. Its belly is white; its tail forked; its gill fins, commonly called its wings, are ſo long, as when laid cloſe to the body to reach the tail, and they are as it were double, a ſmall fin compoſed of a ſeries of ſhort nerves or rays, connected by a ſmall membrane ſtanding before each. Theſe wings are of an olive colour on their upper ſide, and are ſpotted with very beautiful blue ſpots near their edges.

This fiſh, when it pleaſes, is able to riſe out of the water, and fly to a conſiderable diſtance in the air; but when its wings are dry, is obliged to plunge again into the water to moiſten them. It does this often, when purſued by an enemy; and whole ſhoals have been ſeen thus flying together. It is common in the Mediterranean, and ſome other ſeas, but is ſeldom known in ours, nor in any of the colder climates. See a minute and accurate deſcription of the *exocetus volitans*, or *flying-fiſh*, in the Phil. Tranſ. vol. lxviii. part ii. p. 791.

FLYING-*fiſh* is alſo the name of a fiſh of the gurnard kind. See *Supplement* GURNARD.

FLYING *pinion*, is a part of a clock having a fly or fan, whereby to gather air, and ſo bridle the rapidity of the clock's motion, when the weight deſcends in the ſtriking part. See CLOCK.

FOAL, or *colt*, the young of the horse kind. The word colt, simply spoken, is, among the dealers, understood to mean the male kind; the female, or mare colt, being called a filly.

Colts are usually foaled in the beginning of summer, and it is the custom to let them run with the mare till Michaelmas, when they are to be weaned. This is to be done sooner or later, according as the cold weather comes in. Some of them are for not having them weaned till the middle of November, and that three days before the full of the moon, if it happen near that time. And some of the best writers on this subject are of opinion, that we do not let the *foals* suck long enough, and that this is the reason why they are so very long before they are fit for use. These authors are of opinion, that a colt ought always to suck the whole winter, and that this would make them fit for service a great deal sooner than they are at present.

When first weaned, they must be kept in a convenient house, with a low rack and manger for hay and oats, that they may eat freely and easily, and the hay must be very sweet and fine, especially at first; a little wheat bran should be mixed with the oats, in order to keep their bodies open, and make them eat freely and drink freely.

It has been observed, that the eating too much oats has rendered colts blind; but the cause has been wrongly attributed to the heating quality of the oats. If the oats are houfed in a mill before they are given them, though they eat ever so much of them, there never happens any mischief of this kind; but endeavouring with their teeth to break and chew them when whole, they are apt to stretch and swell the vessels of the head, and occasion a fulness of blood about the eyes, which often terminates in inflammations, and in blindness.

The difficulty of chewing oats, and not their heating nature, is therefore the true reason of this mischief; and if this be obviated by firft houfing the grain, the colt always grows the better for eating it. His legs do not grow thick, but he becomes broader and better knit, and as he grows up, will bear fatigue much better than if he had been fed only with bran and hay. Above all things, these creatures are to be kept from wet and cold, while they are young, for nothing is more tender than a colt, and the mischiefs he gets at this time are not so easily overcome. Experience shews the great advantage of houfing and taking care of colts: for if the fame ftallion cover two mares, both alike in age, beauty, and all other particulars, and these being both *foals* of the fame sex, so that there is no room to expect the leaft difference between them; let one of these colts be houfed every winter, and let the other always run abroad, it will be found as they grow up, that the colt which has been kept abroad, shall have large fleshy shoulders, flabby and gouty legs, weak pafterns, and bad hoofs, and fhall be a dull heavy creature; and that the other, which has been houfed and taken care of, fhall have a fine forehand, be well fhaped, have good legs and good hoofs, and be of good ftrength and fpirit. From this it may be learned, that it is of no consequence to have a good ftallion, and a good mare, if the colts are foaled in the breeding up.

It is obferved, that fome colts, under the age of fix months, though the mare yields plenty of good milk, yet decay and wafte daily. They are in this cafe alwa ys troubled with a cough. The breeders have a great many fantaftic remedies in fuch cafes, as the bag wherein the creature was foaled, the lungs of a fox, and the like; but a little liquorice and elecampane powder mixed with honey and milk, is a remedy greatly to be preferred to all thefe.

When the colts are kept up in the winter, they are not to be continually immured in the ftable, but in the middle of the day, when the fun fhines warm, they fhould always be let out to play about for an hour or two; and when the winter is fpent, they fhould be turned into fome dry ground, where the grafs is fweet and fhort, and where there is good water, that they may drink at pleafure. The winter after this, they may be kept in the ftable without any further care than that which is taken of other horfes; but after the firft year, the mare colts and horfe colts are not to be kept together.

This may be the method every fummer and winter till they are broke for ufe, which may be when they are three years old; and they will take the breaking much more eafily, after this fort of breeding, than if they had been all the time running about wild: for ordering them the fecond year as the other horfes are ordered, they will be tame and gentle like them, and will not flounce and plunge about on the firft mounting, as they otherwife would, but will take the faddle quietly. The common way of breaking a colt, by beating him and tiring him by riding over plowed fields, however neceffary it may be to a colt that has always run wild, is not to be chofen when it can be avoided; for it is breaking and fpoiling the creature's fpirit. Uſing him to other horfes, and winning him by gentleneſs, is a vaſtly preferable way. It is proper to wear no fpurs for fome time with a newly backed horfe.

In order to make him endure the *faddle* well, the way is to make it familiar to him, by clapping it with the hands as it lies on his back; then fwaying upon it, and dangling the ftirrups by his fides, rubbing his fides with them, and bringing him thus to be uſed to every thing about him. Then the crupper fhould be often ftrained, the girths looſened and tightened, and the ftirrups taken up and let down at times, all the while making much of him. This will make every thing eaſe to him, and will make him gentle without breaking his fpirit.

As foon as he will not wish the faddle obediently, the mounting of him is to be conſidered. In order to this, put a trench of a full mouth into his mouth, and throw the reins over the fore part of the faddle, fo that he may have full feeling of it; then put on a martingale, buckled at fuch a length, that he may juſtly feel it when he jerks up his head, a broad piece of leather is then to be put round his neck, and the ends made faft by plaiting it, or fome other way at the withers, or before the wind-pipe, about two handfuls below the thropple, between the leather and his neck; but the martingale paſs fo that, at any time when he offers to duck or throw down his head, the cavefion being placed upon the render griſtle of his nofe, may correct and punifh him. This will make him bring his head to, and form him to the rein. See HORSE.

FOCAGE, or FUAGE, fire-money, hearth-money, or chimney-money. See FUAGE.

FOCILE, FOCIL, in *Anatomy*, a name the Arabs give to the two bones of the arm, reaching from the elbow to the wriſt.

The biggeſt, which is what we call the *cubitus*, and *ulna*, they call the *greater focil*, *focile majus*.

The leſs, which we call *radius*, they call *focile minus*.

The like is obſerved with regard to the bones of the leg. The biggeſt of which, by the Latins called *tibia*, the Arab writers, &c. call the *great focil*; and the *leſs*, or *fibula*, the *leſſer focil*.

FOCUS, in *Geometry*, and the *Conic Sections*, is applied to certain points of the *parabola*, *ellipſis*, and *hyperbola*; wherein the rays reflected from all parts of thoſe CURVES do concur or meet.

The FOCI *of an* ELLIPSIS are two points, as F f, *Tab. Conic. Fig.* 21. in the axis AB, on which, as centres, the figure is deſcribed: or, two points in the longer axis, whence two right lines being drawn to any point in the circumference, fhall be together equal to the axis itſelf. Theſe are alſo called *umbilici*. See CONIC *Section*.

To find the *foci* of an *ellipſis*. See ELLIPSIS.

FOCUS *of the hyperbola*. See CONIC *Section*, and HYPERBOLA.

The FOCUS *of a parabola* is a point in its axis, as F (*Tab. Conics, fig.* 38.) wherein the ſemiordinate FN is equal to the ſemiparameter: or, a point in the axis diſtant from the vertex, by a fourth part of the parameter, or latus rectum.

It is demonſtrated in conics, 1. That in a parabola, the diſtance of the *focus* from the vertex, AF, is to the parameter in a ſubquadruple ratio.

2. That the ſquare of the ſemiordinate is quadruple of the rectangle of the diſtance of the *focus* from the vertex, and the abſciſs.

3. That the right line FM, *fig.* 19. drawn from the *focus* F to the extremity of the ſemiordinate of the parabola, is equal to the aggregate of the abſciſs AP, and the diſtance of the *focus* from the vertex AF. See CONIC *Section*.

FOCUS, in *Optics*, is a point wherein ſeveral rays concur, and are collected; either after having undergone refraction, or reflection.

It is thus called, becauſe the rays being here brought together, and united; their force and effect are increaſed; ſo that they become able to burn: accordingly, it is in this point, that bodies are placed to ſuſtain the force of burning glaſſes, or mirrors.

It muſt be obſerved, that the *focus* is not, ſtrictly ſpeaking, a point; the rays are not all accurately collected into the ſame place: Huygens demonſtrates, that the *foci* of a lens convex on both ſides, is $\frac{1}{3}$ of the thickneſs of the lens.

FOCUS, in *Dioptrics*, is the point wherein refracted rays, rendered convergent by refraction, do concur, or meet, and croſs the axis.

The ſame point is alſo called the *point of concourſe*, or *concurrence*.

FOCUS, *Virtual*, in *Dioptrics*, is the point from which refracted rays, when by refraction they are rendered divergent, do begin to diverge, or recede from each other.

The ſame point is alſo called *punctum aſſumptum*, or *point of*

of divergency, in oppoſition to the *focus* which is called the point of concurrence. Suppoſe, e. g. the concavity of a glaſs to be *a b c*, *Tab.* II. *Optics*, *fig.* 21. and its axis *d e*; let *f g* be a ray of light falling on the glaſs parallel to the axis *d e*, and let *d* be the centre of the arc *a b c*. This ray *f g*, after it has paſſed the glaſs, at its emerſion at *g*, will not proceed directly to *h*, but will be refracted from the perpendicular *d g* and become the ray *g i*. Draw then directly *g d*, ſo that it may croſs the axis in *e*. The point *e* ſo found, is called by Mr. Molyneux the virtual *focus* or point of divergence.

The effect of convex glaſſes, or lenſes, is to render the rays, tranſmitted through them, convergent, and to bring them together into a *focus*, which will be nearer or farther off, as the lens is a portion of a greater or leſs ſphere.

The effect of concave lenſes is, to render the rays tranſmitted through them, divergent, or to diſperſe them from a virtual *focus*.

For the place, poſition, diſtance, &c. of the *foci* of rays refracted through plain, convex, and convex mediums of divers denſities, as air, water, glaſs, &c. ſee REFRACTION, LENS, &c.

The laws of the *foci* of glaſſes, and the methods of finding the ſame, being thoſe of moſt uſe and importance; we ſhall here ſubjoin them apart, as delivered and demonſtrated by Mr. Molyneux, in his Dioptrica Nova.

1. The *focus* of a convex glaſs, i. e. the point wherein parallel rays tranſmitted through a convex glaſs, whoſe ſurface is the ſegment of a ſphere, do unite, is diſtant from the pole or vertex of the glaſs, almoſt a diameter and half of the concavity.

2. In a plano-convex glaſs, the *focus* of parallel rays, or the place where they unite with the axis, is diſtant from the pole of the glaſs a diameter of the concavity, provided the ſegment do not exceed thirty degrees.

The rule or canon in plano-convex glaſſes is as 167: 193:: ſo is the radius of the concavity: to the refracted ray taken to its concourſe with the axis; which in glaſſes of larger ſpheres is almoſt equal to the diſtance of the *focus* taken in the axis.

3. In double-convex glaſſes of the ſame ſphere, the *focus* is diſtant from the pole of the glaſs about the radius of the convexity, if the ſegment be but thirty degrees.

But if the convexities be unequal, or if the two ſides be ſegments of different ſpheres, then the rule is,

As the ſum of the radii of both convexities: to the radius of either convexity alone:: ſo is the double radius of the other convexity: to the diſtance of the *focus*.

Here obſerve, that the rays which fall nearer the axis of any glaſs, are not united with it ſo near the pole of the glaſs as thoſe farther off: nor will the *focal* diſtance be ſo great in a plano-convex glaſs, when the convex ſide is towards the object, as when the plain ſide is towards it.

Hence it is truly concluded, that, in viewing any object by a plano-convex glaſs, the convex ſide ſhould always be turned outward; as alſo in burning by ſuch a glaſs.

FOCUS, *for the virtual*, obſerve, 1. That in concave glaſſes, when a ray falls from air parallel to the axis, the virtual *focus*, by its firſt refraction, becomes at the diſtance of a diameter and a half of the concavity.

2. In plano-concave glaſſes, when the rays fall parallel to the axis, the virtual *focus* is diſtant from the glaſs the diameter of the concavity.

3. In plano-concave glaſſes, as 107: 193:: ſo is the radius of the concavity: to the diſtance of the virtual *focus*.

4. In double concaves of the ſame ſphere, the virtual *foci* of parallel rays is as the diſtance of the radius of the concavity.

But, whether the concavities be equal or unequal, the virtual *foci*, or point of divergency of the parallel rays, is determined by this rule;

As the ſum of the radii of both concavities: is to the radius of either concavity:: ſo is the double radius of the other concavity: to the diſtance of the virtual *focus*.

5. In concave-glaſſes, expoſed to converging rays, if the point to which the incident ray converges, be diſtant from the glaſs farther than the virtual *focus* of parallel rays, the rule for finding the virtual *focus* of this ray is this;

As the difference between the diſtance of this point from the glaſs, and the diſtance of the virtual *focus* from the glaſs: is to the diſtance of the virtual *focus*:: ſo is the diſtance of this point of convergence from the glaſs: to the diſtance of the virtual *focus* of this converging ray.

6. In concave glaſſes, if the point to which the incident ray converges, be nearer to the glaſs than the virtual *focus* of parallel rays, the rule to find where it croſſes the axis, is this:

As the exceſs of the virtual *focus*, more than this point of convergency: is to the virtual *focus*:: ſo the diſtance of this point of convergency from the glaſs: is to the diſtance of the point where this ray croſſes the axis.

Rules for finding the FOCI *of glaſſes.*—To find the *focus* of a convex ſpherical glaſs, being of a ſmall ſphere, apply it to the end of a ſcale of inches, and decimal parts, and expoſe it before the ſun; upon the ſcale you will have the bright interſection of the rays meaſured out: or, expoſe it in the hole of a dark chamber: and where a white paper receives the diſtinct repreſentation of diſtinct objects, there is the *focus* of the glaſs.

For a glaſs of a pretty long *focus*, obſerve ſome diſtant object through it, and recede from the glaſs till the eye perceives all in confuſion: or the object begins to appear inverted; here the eye is in the *focus*.

For a plano convex glaſs: make it reflect the ſun againſt a wall; you will on the wall perceive two ſorts of light; one more bright within, another more obſcure: withdraw the glaſs from the wall, till the bright image is in its leaſt dimenſions; the glaſs is then diſtant from the wall about a fourth part of its *focal* length.

For a double convex: expoſe each ſide to the ſun in like manner; and obſerve both the diſtances of the glaſs from the wall. The firſt diſtance is about half the radius of the convexity turned from the ſun; and the ſecond, about half the radius of the other convexity

Thus we have the radii of the two convexities; whence the *focus* is found by this rule:

As the ſum of the radii of both convexities: is to the radius of either convexity:: ſo is the double radius of the other convexity: to the diſtance of the *focus*.

FOCUS, in *Catoptrics*, is a point wherein the rays reflected from the ſurface of a mirror, or ſpeculum, and by reflection rendered convergent, do concur, or meet.

The effect of concave mirrors is to collect the rays falling on the concave ſurface into a *focus*.

The effect of convex mirrors is to diſperſe the rays falling on them, or render them more divergent.

For the laws of the *foci* of rays reflected from mirrors, or ſpecula, ſee MIRRORS.

The *foci* of concave glaſſes are had by reflection: for, as a concave mirror burns at the diſtance of about half the radius of the concavity; ſo a concave glaſs being ſuppoſed a reflecting ſpeculum, unites the rays of the ſun at the diſtance of about half the radius of the concavity.

To find the FOCI *of all ſorts geometrically.*—Dr. Halley furniſhes us with a general method for finding the *foci* of ſpherical glaſſes of all kinds, both concave and convex; expoſed to any kinds of rays, either parallel, converging, or diverging; under the following problem.

To find the *focus* of any parcel of rays diverging from, or converging to, a given point in the axis of a ſpherical lens, and inclined thereto under the ſame angle, the ratio of the ſines of refraction being given:

Suppoſe G I, (*Tab. Optics, fig.* 20.) a lens; P a point in its ſurface; V its pole; C the centre of the ſphere whereof it is a ſegment; O the object, or point in the axis, to or from which the rays do proceed; and O P a given ray: and ſuppoſe the ratio of refraction to be as *r* to *s*. Then making C R to C O, as *s* to *r* for the immerſion of a ray; or as *r* to *s* for the emerſion (i. e. as the ſines of the angles in the medium which the ray enters, to the correſponding ſines in the medium out of which it comes), and laying C R, from C towards O, the point R will be the ſame for all the rays of the point O. Laſtly, drawing the radius P C, if need be, continued; with the centre R, and diſtance O P, ſtrike a piece of an arch, interſecting P C in Q. The line Q R, being drawn, ſhall be parallel to the refracted ray; and P F, being made parallel thereto, ſhall interſect the axis in the point F; the *focus* ſought.

Or, make it, as C Q: C P:: C R: C F, then will C F be the diſtance of the *focus* from the centre of the ſphere.

This author gives a demonſtration of the method; and adds various figures, exhibiting the various caſes of rays either diverging or converging as they enter, or emerge out of, the ſurface either of a convex or concave lens.

From this principle all the rules for the *foci* of rays parallel to the axis, are known: for the principal *focus* where the rays neareſt the axis do unite, are deduced. As,

Hence, 1. If O P be equal to C R; the points Q and C are coincident, and the rays O P, after refraction, run on parallel to the axis. 2. If the point Q fall on the ſame ſide of the axis, as in the point F; then the beams after refraction do tend on, either diverging or converging, as before: but if Q fall on the other ſide the axis, the diverging rays are made to converge by a convex, or the converging to diverge by a concave glaſs. 3. If O P do exceed C R, the *focus* is in all caſes on the ſame ſide of the glaſs, as is the centre of the ſphere C. But contrariwiſe, if O P be leſs than C R, the *focus* falls on the other ſide of the glaſs beyond the vertex V. 4. An object may be ſo placed, that the rays next the axis of a convex glaſs

ſhall

ſhall have an imaginary *focus* tranſmitting diverging rays, when the more remote parts thereof ſhall make them converge to a real *focus*. 5. If OV, the diſtance of the object from the pole or vertex of the glaſs, be taken inſtead of O P, then will C Q be the difference of O V and C R; and as that difference is to C R, ſo is the radius C V to C F, the diſtance of the principal *focus* from the centre of the ſphere, whereof the glaſs is a ſegment. Or elſe, as C Q : O P or R Q : P C : : to V F, the *focal* diſtance from the pole of the glaſs. Whence follows a general rule for the *foci* of all glaſſes; only according to Corol. 3. it O V do exceed C R, the *focus* is on the ſame ſide of the glaſs as the centre of the ſphere: but if C R be greater than the *focus* is on the oppoſite ſide of the glaſs: whence it will be determined whether the *focus* be real or imaginary.

What has been ſaid of one ſurface of the lens, is eaſily applicable to the other, taking F the *focus* for an object.

FODDER, any kind of meat for horſes, or other cattle: in ſome places hay and ſtraw mingled together are more peculiarly denominated *fodder*.

In the civil law it is uſed for a prerogative that the prince has, to be provided of corn, and other meat, for his horſes, by the ſubjects, in his warlike expeditions.

FODDER, in *Mining*, is a meaſure containing twenty-two hundred and a half weight, though in London but twenty hundred weight.

FODINA, a name ſome authors give to the LABYRINTH in the bone of the ear.

FŒCES. See FÆCES.

FŒCIALES. See FECIALES.

FŒCULA. See FÆCULA.

FŒCUNDITY. See FECUNDITY.

FŒNICULUM. See FENNEL.

FŒNUM *Græcum*. See FENUGREEK.

FŒNUM *ſanctum*. See SAINT *Foin*.

FŒTOR, in *Medicine*, ſtinking or fetid EFFLUVIA, proceeding from the body, or the parts thereof.

Fœtors ariſe from ſtagnant, extravaſated, corrupted, or poiſoned humours: as alſo from any thing capable of attenuating and volatilizing the oils and ſalts; as abſtinence, heat, too much motion, acrimony of food, &c.

FŒTOR *narium*, ſtench of the noſtrils: a ſort of diſeaſe ariſing from a deep ulcer within-ſide the noſe, yielding a fetid ſmell.

Its cauſe, according to Galen, is a ſharp humour falling from the brain upon the mamillary proceſſes.

This is one of the cauſes for which marriage might be formerly annulled.

FŒTOR *oris*, a term uſed by medical writers to expreſs that ill ſmell in the mouth, actually, though often, improperly, called by us a ſtinking breath. This is a malady ariſing in different caſes from very different cauſes; as from the ſcurvy, and particularly that ſpecies of it which affects the mouth, and is therefore called *ſtomacace*; from the French pox; from an ulceration whether ſimple or fiſtulous in the lungs, which is the caſe in conſumptions; from ulcers in the mouth; from caries or rottenneſs of the teeth, or from any other impurity of them; from crudities in the ſtomach ariſing from a bad digeſtion, and in particular, from a weakneſs about the left orifice of the ſtomach, from which part the fœtid vapours will often ariſe in very great abundance.

Method of cure. According to the different cauſes of this diſorder, it requires a very different method of cure. In caſes where it depends on the ſcurvy, pox, or other diſeaſes, thoſe diſeaſes are to be attacked by the proper medicines, in order to its cure; when it ariſes from a carious tooth, there is no cure for it, but drawing the tooth; when the impurities of the teeth occaſion it, the cleaning them proves a cure. Juncker's Conſp. Med. p. 607.

FŒTUS, in *Anatomy*, denotes the child, while yet contained in the mother's womb; but particularly after it is perfectly formed; till which time it is more properly called EMBRYO.

The manner of the conception, or generation of the *fœtus*, is matter of great controverſy. That all the parts of the animal did exiſt, and that its fluids were in motion, before generation, is generally allowed; but whether the animalcule was lodged in the male, or female, has been much diſputed. See GENERATION, CONCEPTION, and PREGNANCY.

The firſt thing that appears of a *fœtus*, is the placenta, like a little cloud, on one ſide of the external coat of the egg: about the ſame time the ſpine is grown big enough to be viſible; and a little after the cerebrum and cerebellum appear like two ſmall bladders: next, the eyes ſtand prominent in the head: then the punctum ſaliens, or pulſation of the heart is plainly ſeen. The extremities diſcover themſelves laſt of all.

The formation of the bones in a *fœtus* is very gradual and regularly performed. In the firſt two months there is nothing of a bony nature in the whole; after this, the hardneſs of the parts where the principal bones are to be ſituated becomes by degrees perceptible. Dr. Kerkring deſcribes the progreſs of the oſſification from ſkeletons which he had prepared from *fœtuſes* of two months, and thence up to nine. In the firſt two months, or till the end of that time, there appears not any thing bony; after this in the third and fourth months, and ſo on, the ſeveral parts, one after another, acquire their bony nature. In the firſt ſtages every thing is membranous, where the bones are to be; theſe by degrees tranſmigrate into cartilages; and from theſe by the ſame ſort of change continued, the bones themſelves are by degrees formed. All this is done by nature, by ſuch ſlow, though ſuch certain progreſſions, that the meeſt eye can never ſee it doing, though it eaſily ſees it when done.

While *fœtuſes* continue in the womb, their muſcles commonly act only by their natural contraction, or the *fœtus* is ſaid to be in a ſleeping ſtate; but ſometimes, when its eaſe or preſervation requires a change of ſituation, it ſeems to perform ſome voluntary motions, which are called its *ſtirrings*. The poſture of the child in the womb, is owing to the muſcles being left to their natural contractions, the ſtronger always prevailing, till their antagoniſts exert ſuch a reſiſtance by being ſtretched, as brings them to an equilibrium.

Fœtuſes increaſe proportionally leſs, the longer they continue in the womb. Mauriceau pretends, that the increaſe of a child, is ſixty-four times its own weight in triple the time. Thus he ſays, that at the birth, a child weighs twelve pounds, of fifteen ounces each; at the three months, it weighs three ounces; at one month ℥ of a drachm; and at ten days leſs than half a grain. Monro in Med. Eſſ. Edinb. vol. ii. p. 142.

FŒTUS, *in the womb, ſituation of the.* The *fœtus*, when formed, is almoſt of an oval figure, while it lies in the womb: for its head hangs down, with its chin upon the breaſt: its back is round; with its arms it embraces its knees, which are drawn up to its belly, and its heels are cloſe to its buttocks; its head upwards, and its face towards its mother's belly. About the ninth month, its head, which was hitherto ſpecifically lighter than any other part, becomes ſpecifically heavier, its bulk bearing a much ſmaller proportion to its ſubſtance than it did.

The conſequence of this change is, that it tumbles in the liquor which contains it; its head falls down, its feet get up, and its face turns towards its mother's back. But being now in an inſome poſture, though, at the ſame time, a favourable one for its exit, the motion it makes for its relief gives frequent pains to the mother, which cauſe a contraction of the womb for the expulſion of the *fœtus*.

What ſome anatomiſts pretend to allege farther as to the poſture of the *fœtus* in the womb, in the ſeveral ſtages of geſtation, is very precarious.

In the firſt month it is of no moment how it lies in the womb: in the latter months, after the *fœtus* is grown not only quick, but robuſt, it frequently changes its poſture of itſelf; as not only the mothers themſelves feel, but any other perſon, by laying the hand on their belliet, frequently may. However, its ordinary poſture is ſuppoſed to be ſitting: as the time of birth draws near, it turns itſelf, and preſents the head to the os uteri; though ſometimes it offers the feet firſt, and ſometimes lies acroſs, and offers either a hand, a knee, or the like: theſe are irregular ſituations, and without conſiderable addreſs of the midwife in turning the *fœtus*, both the mother and the infant are in danger. See DELIVERY.

FŒTUS, *anatomy of the.* The *fœtus* is incloſed in two membranes, or coats; the inner, which immediately inveſts the *fœtus*, and the liquor wherein it lies, is called the AMNION; the outward membrane is called the CHORION.

In ſome animals there is a third membrane, called the ALLANTOIS, whoſe place is between the other two, and which ſerves for the diſcharge of the urine of the *fœtus*, brought hither by the urachus.

Dr. Needham ſeems to have diſcovered ſomething analogous herein in the human *fœtus*, and calls it the *membrana urinaria*: but others chuſe only to make it a duplicate of the chorion; though the neceſſity of ſuch third membrane be the ſame in men, as in cows, ſheep, &c.

There are ſome differences in the ſtructure, mechaniſm, and proportion of the parts of a *fœtus*, from thoſe of an adult; and even ſome additional and extraordinary parts, by which the nutrition of this zoophyte, or plant-animal, as it is called, and the circulation of the blood therein, are effected.

The principal variations are about the liver, heart, and lungs.

Of

Of theſe, the moſt conſiderable are the umbilical veſſels, which are two arteries, a vein, and the urachus, ariſing from the placenta, and conveyed through the navel to the liver of the *fœtus*, near the navel; all which, after the birth, drying up, become impervious and uſeleſs.

In the liver itſelf there is an extraordinary communication between the porta and cava, called *canalis venoſus*, which, after the birth, gradually dries up. In the heart, at the mouth of the vena cava, is the foramen ovale, whereby that vein has a communication with the pulmonary vein: there is alſo a communication between the aorta and pulmonary artery, by means of the canalis arteriofus, which paſſes between the two, at about two inches diſtance from the baſe of the heart. It is by means of theſe two canals or paſſages, that the blood has been ſuppoſed to circulate in the *fœtus* while incloſed in the womb; they ſerving to convey and paſs the blood from the heart into the arteries, and from the veins into the heart again, without its paſſing through the lungs, which are now uſeleſs.

The lungs of a *fœtus* are of a darker colour, and cloſer conſiſtence, than after they have been breathed into, as appears from their ſwimming in water after birth, which they will not do before; which difference has been ſaid to afford an uſeful experiment, in caſe of the ſuſpected murder of children: for if they were ſtill-born, the lungs ſink in water; if born alive, they ſwim. But this notion is not well founded; becauſe the uninflated lungs become ſpecifically lighter than water as ſoon as any degree of putrefaction takes place in them, and this happens ſoon after the death of the child: beſides, where the utmoſt care has been taken to preſerve the child, it has breathed once or twice, and then died.

The two canals above mentioned ſerve only to prevent the obſtruction the blood would otherwiſe have within the lungs, before they have been opened. After reſpiration has opened the lungs, the blood taking its courſe through them, thoſe paſſages cloſe up.

The head of the *fœtus* is much bigger in proportion to the body than afterwards; the bones and brains are ſofter, the ſutures open, and they leave a great ſpace on the top of the head, covered only with a membrane; and the glands, particularly the thymus and renales, are bigger and ſofter. From other differences in the proportion, ſee EMBRYO.

FOETUS, *nutrition of the.* How the nutrition of the *fœtus* is performed, is diſputed among the learned. Heiſter is of opinion, that the nutrition of the *fœtus*, during the firſt months, while the organs of concoction are not yet formed, is probably effected by means of the navel-ſtring alone. But in the more advanced ſtate of the *fœtus*, in the latter months, he ſuppoſes, that it is alſo nouriſhed by the mouth, by means of a ſoft and ſomewhat gelatinous fluid that ſurrounds it, and which is probably ſecreted from the amnios: in ſupport of which opinion he obſerves, 1. That a fluid ſimilar to that of the amnios is found in the mouth, the œſophagus, and the ſtomach, not only of the human *fœtus*, but in that of quadrupeds. 2. That this fluid is alſo found in the ſmall guts of the *fœtus*, but altered and digeſted. 3. That there are alſo found in the larger inteſtines real fæces, called meconium: ſometimes the whole ilium is full of theſe. 4. That in the firſt months there is a great quantity of this fluid ſurrounding the *fœtus*; but in the latter months, there is little of it, and the conſumption of it is not eaſily accounted for in any other way than by its being ſwallowed by the *fœtus*. 5. That the liquid itſelf is ſo extremely proper for the nutrition of the *fœtus*, that a more fit one could not be formed or deſired. 6. That it ſeems to be continually preſſed into the mouth, œſophagus, and ſtomach of the *fœtus*, by the perpetual reſiliency of the uterus itſelf, and by the preſſure of the muſcles of the abdomen, and of the ambient air.

Hippocrates, among the ancients, was of opinion, that the *fœtus* was nouriſhed both by the mouth, and by the umbilical veſſels. He maintains, that the child in the womb, with its lips compreſſed together, attracts nouriſhment; for which he aſſigns this reaſon, that unleſs the child had ſucked in utero, it neither could depoſit excrement, nor know how to ſuck ſo ſoon as it is born. The celebrated Harvey maintained this doctrine; only that he ſubſtituted an albuginous aliment in place of Hippocrates's menſtrual blood. Mr. Gibſon, in the Medical Eſſays of Edinburgh, vol. i. p. 140. has alſo adopted this opinion, that the *fœtus* is nouriſhed by the mouth and by the navel alſo, as moſt probable.

He alledges, that the fluid contained in the amnios, and in which the *fœtus* ſwims, is not an excrementitious liquor, but a *materia nutricula*; ſo that it is found in very conſiderable quantities, before the parts of the *fœtus* are viſibly delineated; and nature hath provided the delicate membrane, called the allantois, principally for preventing the urine of the *fœtus* from mixing with the liquor amnii, its food. Farther, the mouth, may even its chaſm, long before the lips are obſervable, is always open; for air blown up it through a pipe will evidently ſeparate its ſides: and Haller remarks to this purpoſe, that he has more than once, in the cold winter ſeaſon, found the liquor amnii frozen, and continued through the mouth and œſophagus to the ſtomach in a pretty large column. Mr. Gibſon adds, that there have been examples of human *fœtuſes*, which have been brought into the world alive, either altogether wanting the umbilicus and its veſſels, or, at leaſt, having the umbilical rope broke aſunder. He then ſubjoins two analogical arguments in confirmation of this opinion, concerning the nutrition of the *fœtus* by the mouth and the umbilical veſſels, viz. one, deduced from the vegetation of plants, which, he ſays, in ſeminе have two roots, the ſeminal, whoſe fibres are inſerted into the cotyledones of the ſeed; and the plantal, which ſucceeds the former, and ſuperſedes the uſe of the cotyledones, which die and fall off: and the other, from the apparatus for nouriſhing the chick in ovo; the albumen ovi anſwering the ſame purpoſe, with regard to the chick, as the liquor amnii does with reſpect to the *fœtus* in animals.

Dr. Fleming has lately produced a fact in ſupport of this hypotheſis, viz. that he had found hairs in the meconium of the *fœtus* of a calf: theſe, he apprehends, were looſened from the ſkin, and afterwards floating in the liquor amnii, were propelled with it into the ſtomach and inteſtines by the alimentary paſſage. But from a ſingle fact no general concluſion can be ſatisfactorily deduced. He adds, as a proof of the alimentary nature of the liquor amnii, that it is concretable by heat, like the yolk of an egg. Phil. Tranſ. vol. xlix. art. 42.

Dr. Monro, on the contrary, is of opinion that the *fœtus* in viviparous animals is nouriſhed by the navel alone. He has given a curious diſſertation on this ſubject in the Medical Eſſays, vol. ii. p. 102, &c. where he obſerves, 1. That the *fœtus* is capable of receiving its whole nouriſhment by the umbilical vein alone, whereas no *fœtus* can ſubſiſt without the umbilical veſſels. 2. That the liquor of the amnios is ill calculated, in its natural ſtate, for the food of a *fœtus*; and becomes altogether unfit food in morbid caſes. 3. That it is highly improbable that a creature ſhould furniſh its ſubſiſtence out of its own body, which muſt be the caſe, if the *fœtus* feeds on the liquor of the amnios. 4. That it cannot be inferred from any reſemblance of the liquor of the ſtomach and amnios, nor from any other appearances, that the liquor of the amnios is ever ſent down into the ſtomach. 5. That no direct proof can be had of the liquor of the amnios being preſſed or ſwallowed down; but, on the contrary, all circumſtances make it probable, that it does not go down. 6. That all the phenomena of a *fœtus* can moſt reaſonably be accounted for, without ſuppoſing the liquor of the amnios to be any part of its food; hence he thinks it reaſonable to exclude the mouth from the office of conveying the aliment of the *fœtuſes* of viviparous animals, and to believe that all their nouriſhment is conveyed by the umbilical veſſels.

Dr. Monro has alſo given us ſeveral curious obſervations relating to the queſtion about the nutrition of the *fœtuſes* of oviparous animals.

He has alſo there conſidered the nouriſhment of plants in a *fœtus* ſtate. And he ſhews the analogy there is between theſe and animal *fœtuſes*. To fix the analogy between animals and plants, he obſerves, that the former may be ſaid to remain in the ſtate of a *fœtus*, ſo long as the young creature is ſolely nouriſhed by liquors furniſhed by the uterus of the parent; and plants are to be conſidered as *fœtuſes* only, while the ſeed is ripening, and before the earth, water, moiſture of the air, &c. have communicated immediately any matter for its increaſe.

The ſame author has given us ſome practical corollaries, from his eſſay on the nutrition of *fœtuſes* of viparous animals, where he makes ſeveral very juſt obſervations relating to abortion, its cauſes, and the method of preventing it in many caſes.

The liquors ſent into the *fœtus* by the umbilical vein, not having their propelling force communicated from the mother, the ſtate of the mother's pulſe cannot affect the child otherwiſe than by occaſioning abortion, or vitiating the fluids. Hence the impreſſions ſaid to be made on children by the imagination of their mother, cannot be accounted for phyſically. Hence alſo children may be infected with the diſeaſed juices of the mother, but it is poſſible for them to eſcape catching their mother's diſeaſes, if either theſe be only topical, without affecting the whole maſs of the fluids; or even when the mother's blood is ſpoiled, the child may be free of her diſeaſe, if the morbid particles be ſuch as the placentary veſſels cannot abſorb.

The mother supplies liquors to the *fœtus*, which returns others to the mother, by means of the diverse and umbilical vessels. This seems proved from observations; for many white placenta were not in the least separated from the uterus, having been quite exhausted of blood by the mother's purge of an hæmorrhage; and Dr Monro acquaints us, that he has seen children pale and weak by violent bleedings in the time of labour.

The liquors are not carried from the mother to the *fœtus* or from the *fœtus* to the mother by continued canals. That is, the uterine arteries and veins do not anastomose with the veins and arteries of the fœtus; but the extremities of the umbilical vein take up the liquors by absorption, in the same way as the lacteal vessels do in the guts; and the umbilical arteries pour their liquors into the large cavities of the sinuses, or other cavities analogous to these.

It is a question, whence the *fœtus* has its red blood. Dr. Monro answers, that *fœtus* in viviparous animals have their red blood from the same source that chickens in ovo have theirs; which can be no other than the action of their heart, and of the vessels of their body and secretions. Med. Ess. Ed. vol. iv. p. 185, 204, 206.

A liquor is found in the thorax of *fœtuses*, which Mr. Petit imagines to be secreted by the thymus. See Mem. de l'Acad. des Sciences, 1733.

Respiration seems to be the great act by which the change is made in animals, from the state of *fœtus* to that of mature, perfect, and the other qualities of animal life in their larger degree. M. Duverney observed this in the *fœtus* of a common snake; he broke the egg of one of these animals, at a time when it was just ready for hatching, and the young snake fell out rolled in a spiral, at first quite still and immoveable; but it had no sooner breathed three or four times than it began to perform all the motions of animal life, in the most nimble and active manner.

FETUS, *circulation of the blood of a.* See BLOOD.

Mr. Wolff, a late writer, has gone a great way towards demolishing both the system of Galen and Harvey, and that of Malpighi, with regard to the circulation of the blood in the *fœtus*. The former, that it neither does, nor can pass from the right auricle to the left, nor from the left to the right, through the foramen ovale. In support of this assertion he observes, that there is a fruchruinism in the motion of the auricles of the heart, the systole and diastole happening, precisely, at the same moment of time; and, therefore, the force that is necessary to make the blood pass from one auricle into the other, cannot exert itself during the systole, because the two auricles are equally and simultaneously contracted, and throw out the blood with which they are filled; nor can it be exerted during the diastole, because the two auricles are then dilated, and receive contiguous blood from whatever part it comes: consequently, there is no moment of time in which the blood can pass from one auricle into the other. In dissecting the heart of a new-born child, Mr. Wolff discovered, that the structure of the organ of circulation in the *fœtus* is very different from what it was commonly imagined to be: for he found, that the aperture on the left side of it was very different from that on the right; the first being formed by that which foreigners call the ora of Vieussens and the valve of Eustachius, and the second being derived from the same ara and the valves of the foramen ovale: and from a further examination of this structure it appeared, that the auricles had no communication with each other, but were separated by the inferior trunk of the vena cava; the aperture which is discernible in the right auricle being nothing more than the orifice of the cava, which effects its insertion into that auricle, while the aperture that is seen on the left side, and called the foramen ovale, is no more than another orifice of the same vein, which has its insertion in the left auricle. Thus both the auricles communicate with the vena cava, but have no communication with each other, and the foramen ovale is only the left orifice of the inferior vena cava. In order to determine the direction which the blood follows in its circulation, we are to consider, that, as the vena cava opens itself by its two orifices in the two auricles or glandes of the heart, the blood which it contains must be conveyed partly into the right auricle by the right orifice, and partly into the left auricle by the left orifice; and the quantity of blood, which discharges itself into the right auricle, mixing itself there with the blood of the superior vena cava, flows directly from thence into the right ventricle of the heart; nor can the least drop of blood, that has once got into the right auricle, return from thence to the left: and the quantity of blood, which passes from the inferior cava, through its left orifice, into the left auricle of the heart, contributes to disengage the lungs, by turning its direction from the right auricle, the right ventricle, and consequently from the lungs, which, being destitute of respiration, could not have transmitted this blood, to facilitated its passage. That portion of blood, therefore, mixing itself in the left auricle with that of the pulmonary veins, proceeds directly to the left ventricle, and from thence into the aorta; from whence it takes its course away in different channels through the whole body, without touching the lungs. Nov. Comment Acad. Scient. Imp. Petropol. vol. xx. 1775

The *fœtus* often dies in the womb. This is discovered to be the case by the following symptoms: the mother becomes languid and weak, and is subject to frequent faintings. She complains also of lying hears and chilnesses, succeeding one another at short intervals, and of straitness of the præcordia, anxieties of mind, and vertiginous dizziness of the head. The breasts, though before distended and hard, grow flaccid on this, and have an abundance of a thin watery serum in them. The *fœtus* is not perceived to move, and the belly hangs upon the thighs with an uncommon dead weight, and is affected with a remarkable coldness.

The death of the *fœtus* is often owing to a remarkably plethoric state of the mother; and yet more frequently to her violent passions, whether of grief, anger, fear, or any other kind. The morbid constitution of the mother may also occasion it, be it almost of any kind whatever, and also habitual diarrhœas. But the death of the *fœtus* is most frequently occasioned by the bad success of labour-pains, or bad attendance in them, and by its being ill conducted by the women.

The expulsion of the dead child is to be attempted by all the forcing medicines such as borax, and the like; and the spirits and strengths are to be kept up during the attempt, by giving analeptics in the intermediate time; but if these medicines have not the desired effect, the manual operation of the man-midwife must be called in; and when the *fœtus* is taken out, the woman is to be treated with the utmost care in the common way of lying-in women. See DELIVERY.

Bartholine, in his treatise De Infolii Partu Vitii, relates a great many stupendous cases of *fœtuses* dead and putrefied in the womb, the parts of which have made their way through apothemations; one whereof, at the navel, was some years in coming away. And in the Philosoph. Transactions we meet with the like instances; particularly of one voided piece-meal by the anus, several years after conception.

Authors give accounts of *fœtuses* found in the Fallopian tubes, and others in the cavity of the belly. M de S. Maurice, in the Memoirs of the Royal Academy of Sciences, relates the history of a *fœtus* formed in the ovary of the mother, and which, at three months from impregnation, bursting the testicle, forced its way through, into the epigastric region.

Others have occasioned abscesses, on the opening of which a passage has been made for the *fœtus*, which has come away by piece-meal.

The story of Margaret, countess of Holland, who is said to have been delivered of 364 *fœtuses*, all alive, and afterwards baptized, passes for a fable; and yet there is a picture of this notable delivery still preserved in the church of Loddane, as a monument of the truth thereof. Albertus Magnus gives a like instance of a woman, who brought forth 150 *fœtuses*, or embryos, all formed, as big as a little finger.

FOG, or *mist*, a meteor, consisting of gross vapours, floating near the surface of the earth.

If the vapours, plentifully exhaled from the earth and waters, either by the solar or subterraneous heat, meet, at their first entrance into the atmosphere, with cold enough to condense them considerably, their specific gravity being thereby increased, their ascent will be stopped, and they will either return back in form of a dew, or of drizzling rain; or they will remain suspended for some time, in form of a *fog*. See EVAPORATION.

Fogs are only low clouds, or clouds in the lowest region of the air; and clouds are no other than *fogs* raised on high.

Objects viewed through *fogs* appear larger, and more remote, than through the common air.

The filling for herring is chiefly practised in *foggy* weather.

FOGAGE, in the *Forest law*, is rank grass, not eaten in the summer.

FOIBLE, a French term, frequently used also in our language.

It literally signifies *weak*; and in that sense is applied to the body of animals, and the parts thereof: as, *foible reins, foible sight, &c.* being derived from the Italian *fievole*, of the Latin *flebilis, to be lamented, pitied.*

But it is chiefly used with us substantively to denote a defect,

defect, or flaw, in a perſon, or thing. Thus we ſay, every perſon has his *foible*; and the great ſecret conſiſts in hiding it artfully: princes are gained by flattery, that is their *foible*: the *foible* of young people is pleaſure; the *foible* of old men is avarice; the *foible* of the great and learned is vanity; the *foible* of women and girls, coquetry, and an affectation of having gallants.

It is a term alſo uſed in fencing, to denote the weakeſt part of a blade; in oppoſition to the ſtrong, or ſtrongeſt.

FOIL, in *Fencing*, denotes a blunt ſword, or one that has a button at the end covered with leather, uſed in learning the art of fencing.

FOIL, among *Jewellers*, a thin leaf of metal, placed under a precious ſtone, in order to make it look tranſparent, to improve the colour, or to give it an agreeable different colour, either deep or pale. Thus, the effect of giving luſtre is produced by the poliſh of the ſurface of the *foil*, which is colourleſs; but if a ſtone is wanted to be of a pale colour, a *foil* of that colour muſt be put under it; if deep, a dark one muſt be laid under it.

Theſe *foils* are made either of copper, tin, gold, or gold and ſilver together: the copper *foils* are generally known by the name of Nuremberg or German *foils*. They are prepared as follows.

Procure the thinneſt copper-plates that can be got; beat theſe plates gently upon a well-poliſhed anvil, with a poliſhed hammer, as thin as writing paper: or paſs them between a pair of ſine ſteel rollers, very cloſe ſet; and placing them between two iron plates, as thin as poſſible, heat them in the fire: then boil the *foils* in a pipkin, with equal quantities of tartar and ſalt, conſtantly ſtirring them, until by boiling they become white; after which, taking them one and one out, dry them, give them another hammering, until they are fit for uſe. Care however muſt be taken, not to give the *foils* too much heat, for fear of melting: neither muſt they be too long boiled, for fear of attracting too much ſalt.

The manner of poliſhing theſe *foils* is as follows: take a plate of the beſt copper, one foot long, and about five or ſix inches wide, poliſhed to the greateſt perfection; bend this to a long convex, faſten it upon half a roll, and fix it to a bench or table: then take ſome chalk, waſhed as clean as poſſible, and ſifted through a fine linen cloth, until it be as ſine as can be made; having laid ſome of this upon the roll, and wetted the copper all over, lay the *foils* upon it, and, with a poliſhed ſtone and the chalk, poliſh them till they are as bright as a looking-glaſs. After this they muſt be dried, and laid up ſecure from duſt.

The beſt method of preparing *foils*, ſo as to give to colourleſs ſtones, as cryſtals, pebbles or paſte, the luſtre and play of diamonds, is as follows:

Take leaves of tin, prepared in the ſame manner as for ſilvering looking-glaſſes, and cut them into ſmall pieces, of ſuch ſize as to cover the ſurface of the ſocket of the ſtones that are to be ſet: lay three of theſe one upon another, and, having moiſtened the inſide of the ſocket with thin gum water, and ſuffered it to dry, that only a ſlight thickneſs may remain, put the three pieces of leaves, lying on each other, into it, and adapt them to the ſurface in as even a manner as poſſible. When this is done, heat the ſocket, and fill it with warm quickſilver, which muſt be left in it for three or four minutes, and then gently poured out. The ſtone muſt then be thruſt into the ſocket, and cloſed with it: care having been previouſly taken, that it may enter the ſocket without ſlipping off the tin and quickſilver from any part of the ſurface. The work ſhould be well cloſed round the ſtone, to prevent the tin and quickſilver contained in the ſocket from being ſhaken out by any violence. The luſtre of ſtones ſet in this manner, will continue longer than when they are ſet in the common way.

When colouring *foils* are wanted, thoſe of copper, above deſcribed, may be either tinged with ſmoke, or ſtained or painted with ſome pigment or other colouring ſubſtance. The colours uſed for this purpoſe, may be tempered with oil, gummed or fixed waters, or varniſh: for red, in imitation of ruby, carmine, with a little lake uſed in ſinglaſs ſize, or ſhell-lac varniſh, or bright lake in oil, ſhould be employed; for the garnet red, dragon's blood, diſſolved in ſeed-lac varniſh, may be uſed; and for the vinegar garnet, orange lake, tempered with ſhell-lac varniſh. For the amethyſt, lake, with a little Pruſſian blue, uſed with oil, or blue; where the effect of ſapphire is wanted, Pruſſian blue in oil, and ſpread on the *foil* more or leſs thinly, according to the lightneſs or deepneſs of the colour required; for the eagle marine, common verdigriſe with a little Pruſſian blue, tempered in ſhell-lac varniſh, ſhould be uſed; for a full yellow, yellow lacquer: and for the ſlighter colour of topazes, the burniſh and *foil* itſelf will ſerve, without any addition. For a deep green, the cryſtal of verdigriſe, tempered in ſhell-lac varniſh; but for the emerald, a little yellow lacquer ſhould be added. See DOUBLETS. Handmaid to the Arts, vol. ii. p. 333, &c.

FOIL, or FOYLE, among *Looking-glaſs-grinders*, a ſheet of tin, with quickſilver, or the like, laid on the back-ſide of a looking-glaſs, to make it reflect. See FOILATING.

The word is formed of the Latin *folium*, leaf.

FOILING, among *Hunters*, the footing and treading of deer, which remains on the graſs, but ſcarce viſible.

FOLC-*land*. See FOLK-*land*.

FOLDAGE and FOLK-COURSE. See FALDAGE.

FOLD-*net*, among *Sportſmen*, a ſort of net with which ſmall birds are taken in the night: there are two ſides of it, the leaſt may be managed by one man, but the largeſt muſt be carried by two, and uſed thus: let the net be fixed on both ſides in two ſtrong poles about twelve feet long, each man holding one of them; let a third carry lights behind them, at the diſtance of two yards: the net ſhould be carried between the wind and the birds, which rooſt on their perches with their breaſts againſt the wind: another perſon, who beats the buſhes on the other ſide of the hedge, will drive out the birds towards the light.

FOLD-*leet*, in *Law*. See FALDAGE.

FOLDS, in the *Manufactures*. See CLOTH, &c.

FOLDS *of the drapery*, in *Painting*. See DRAPERY.

FOLDING *of ſheep*. See SHEEP.

FOLIA, in *Botany*, is uſed for the leaves of plants, and alſo of flowers, but particularly the former; the leaves of flowers being more properly called PETALA.

FOLIACEUM *expanſum*, in *Anatomy*, is that extreme of the FALLOPIAN *tube*, next the ovary; and which is expanded like the mouth of a trumpet, and invironed with a ſort of fringe.

FOLIAGE, a cluſter or aſſemblage of flowers, branches, leaves, &c.

FOLIAGE is generally uſed for repreſentations of ſuch flowers, leaves, branches, fruits, &c. whether natural or artificial; uſed as enrichments on CAPITALS, FREEZE, PEDIMENTS, &c. See *Tab. Archit. fig.* 12.

FOLIATE, in the *Higher Geometry*, a name given by ſome to a curve of the ſecond order, expreſſed by the equation $x^3 + y^3 = axy$, being one ſpecies of deficient hyperbolas, with one aſymptote, and conſiſting of two infinite legs croſſing one another, and forming a ſort of leaf.

FOLIATING *of looking-glaſſes*, is the ſpreading a compoſition of ſomething which will firmly adhere to the back of the glaſs, and there reflect the image.

This compoſition is called the *foil*, and is uſually made with quickſilver, mixed with tin, and ſome other ingredients.

For the method of *foiliating* looking glaſſes, ſee LOOKING-GLASS.

In Philoſoph. Tranſ. N° 245. we have a method of *foiliating* globe looking-glaſſes, communicated by Mr. Southwell. The mixture is of quickſilver and biſmuth, of each three ounces; and tin and lead, of each half an ounce: to the two laſt throw on the marcaſſite, and afterwards the quickſilver; ſtir them well together over the fire; but they muſt be taken off, and be towards cooling before the quickſilver be put to them.

When you uſe it, the glaſs ſhould be well heated, and very dry, but it will do alſo when it is cold, though beſt when the glaſs is heated.

Mr Boyle's method, which he prefers to any he ever met with in print, is this: take tin and lead, of each one part; melt them together, and immediately add of good tin glaſs, or biſmuth, two parts; carefully ſkim off the droſs; then take the crucible from the fire, and, before the mixture grows cold, add thereto ten parts of clean quickſilver, and having ſtirred them well all together keep the fluid in a new clean glaſs. When you go to uſe it, firſt purge it, by draining it through linen, and gently pour ſome ounces into the glaſs to be *foiliated*, through a narrow paper funnel, reaching almoſt to the glaſs, to prevent the liquor from flying to the ſides. After this, by carefully inclining the glaſs every way, and endeavour to ſubmit to the internal ſurface; which done, let it reſt for ſome hours; then repeat the ſame operation and ſo continue at times, till the liquor is ſlowly paſſed over, and equally fixed to the whole ſuperficies; which may be diſcerned by expoſing the glaſs to the eye between that and the light. Boyle's Works abr. vol. i. p. 196.

FOLIATION, in *Botany*, &c. is uſed by Dr. Grew, to expreſs the aſſemblage of the FOLIA, or PETALA, of a flower.

The *foliation* is the moſt conſpicuous part of flowers, being that collection of figaceous, coloured leaves, which conſtitutes the compaſs, or body of the flower.

It is of great uſe in the generation and preſervation of the young fruit, or ſeed: it ſtrates a fine juice, to nourriſh it in the uterus, or piſtil.

In ſome ſpecies, as apricots, cherries, &c. it likewiſe ſerves

to

to guard the young tender fruit from the violence of wind, weather, &c. for this, being of a very tender and pulpous body, and coming forth in the colder times of the spring, would be often injured by the extremities of weather, if it were not thus protected, and lodged within the flowers.

Before the flowers open, the *foliation* is curiously and artfully folded up in the calyx or perianthium.

Dr. Grew enumerates several varieties of their foldings, viz. the *close couch*, as in roses; the *concave couch*, as in the blattaria flore alho; the *single-plait*, as in pea blossoms; the *crowfoot plait*, as in marigolds; and the *reuel*, as in the ladies flower.

FOLIO, or rather FOLIUM, in books of account, &c. signifies *page*.

Thus *folio* 7. written abridgedly F° 7. denotes the seventh page, &c.

Folio recto, or F° R°, expresses the first side or page of a leaf.

Folio verso, or F° V° the second, or back-side of the leaf.

The word is Italian, and literally signifies *leaf*.

FOLIO, among *Booksellers*, a BOOK in *folio*; or simply, a *folio*, is that where the sheet is only folded in two, each leaf making half a sheet.

Beneath the *folio* are the *quarto*, *octavo*, *duodecimo*, *sixteens*, *twenty-fours*, &c.

FOLIS, or FOLLIS, anciently signified a little bag or purse; whence it came to be used for a sum of money, and very different sums were called by that name: thus, the scholiast on the Basilics, mentions a *follis* of copper which was worth but the twenty-fourth part of the MILIARENSIS; the glossæ nomicæ, quoted by Gronovius and others, one of a hundred and twenty-five miliarenses, and another of two hundred and fifty denarii, which was the ancient sestertium; and three different sums of eight, forty, and two pound of gold, were each, called *folles*. According to the account of the scholiast, the ounce of silver, which contained five miliarenses of sixty in the pound, was worth a hundred and twenty *folles* of copper. The glossographer, describing a *follis* of two hundred and fifty denarii, says it was equal to three hundred and twelve pounds six ounces of copper; and as the denarius of that age was the eighth part of an ounce, an ounce of silver must have been worth a hundred and twenty ounces of copper; and, therefore, the scholiast's *follis* was an ounce of copper, and equal to the glossographer's *nummus*. But as Constantine's copper money weighed a quarter of a Roman ounce, the scholiast's *follis* and the glossographer's nummus contained four of them, as the ancient nummus contained four asses. See Phil. Trans. vol. lxi. ii. p. 515, &c.

FOLIUM. See LEAF.

FOLIUM *branchiarum*, *the leaf of the gills*, a term used by some of the ichthyologists, to express that part of the gills which looks red and fringed. The gills of fish are composed of certain bony circles, which are formed on the convex side with a great number of laminæ; these serve to receive the ramifications of the arteries, and are called the *folium* or leaf of the gills. The aorta or great artery reaches no farther than this part in fish. It has no descending trunk, but every part of the body is supplied by a large vesal trunk, formed by the joining of the several smaller trunks of the several circles of the gills.

FOLIUM *caryophyllatum*, or clove-leaf. See CLOVE-*tree*.

FOLIUM *Indicum*, or *Indum*, called also TAMALAPATRA, and MALABATHRUM; a leaf brought from the Indies, growing chiefly about Cambaye, produced by a tree not unlike the lemon-tree; used in the compolition of Venice-treacle.

FOLK-LAND, in our ancient Saxon cuſtoms, denoted COPYHOLD *lands*.

In oppoſition to theſe, charter-lands were called *book-lands*, or BOCK-*lands*.

Fundus ſine ſcripto poſſeſſus (ſays Somner) *cenſum penſtans annuum. Et ſpectorum ſervituti obnoxius: terra popularis.*

FOLKMOTE, FOLCMOTE, or FOLKESMOTE, among our Saxon anceſtors, ſignified any popular or public meeting of all the folk or people of a place, diſtrict, or the like; e. gr. of all the tenants of a court-leet, or court-baron; or of all the freemen of the county; or of all the barons, of a kingdom

The word, ſays Stow, is ſtill in uſe among the Londoners, and ſignifies *celebrem ex omni civitate conventum*, an aſſembly of all the citizens. Manwood ſays it is the court holden in London, wherein all the folk and people of the city did complain of the mayor and aldermen for any miſgovernment.

Somner, in his Saxon Dictionary, makes *folcmote* to denote a general aſſembly of the people, for doing fealty to the king, and conſidering and ordering matters of the commonwealth; whence ſome date the origin of parliaments.

Omnes proceres regni, & milites & liberi homines univerſi totius regni Britannie, facere debent in pleno folcmote *fidelitatem domino regi, coram epiſcopis regni. In* Leg. Edw. Confeſſ. cap. 33. *Et amplius non ſit in huſſingis, miſſenningis*, i. e. ſpeaking amiſs; *neque in* folkeſmote, *neque in aliis placitis infra civitatem.* Charta H. I. pro London. Du-Cange.

When ſuch aſſembly is made in a city, it may be called a *burghmote*; when in the county, a *ſhiregemote*.

Cum aliquid vero inopinatum & malum contra regnum vel contra coronam regis emerſerit, ſtatim debent, quibuſdis campanis, quod Anglice vocatur mothel, *convocare omnes & univerſos, quod Anglici vocant* folkmote, &c. Leg. Alfred.

FOLLICULUS, among *Gardeners*, the ſeed-veſſel, caſe, coat, huſk, or cover, wherewith ſeveral kinds of ſeeds and fruits are incloſed.

FOLLICULUS *felleus*. See GALL-*bladder*.

FOLLY, according to Mr. Locke, conſiſts in the drawing of falſe concluſions from juſt principles; by which it is diſtinguiſhed from madneſs, which draws juſt concluſions from falſe principles.

But this ſeems too confined a definition; *folly*, in its moſt general acceptation, denoting a weakneſs of intellect or apprehenſion, or ſome partial abſurdity in ſentiment or conduct.'

FOMAHANT, or FOMALHAUT, in *Aſtronomy*, a ſtar of the firſt magnitude, in the water of the conſtellation AQUARIUS.

FOMENTATION, a liquid medicine, applied to any diſeaſed part, to reſolve, diſcuſs, ſoften, aſſwage, fortify, or conſtringe the ſame.

Fomentation are either *ſimple* or *compound*.

FOMENTATIONS, *compound*, are decoctions of roots, leaves, flowers, and ſeeds, made in common water, or other proper liquor, to which are ſometimes added ſalts, axungiæ, oils, &c.

To uſe, or apply them, they dip a hot linen cloth, or flannel, in the liquor, and ſpread it on the part affected.

There are alſo *fomentations* made another way, viz. by boiling certain drugs in linen bags, and then applying them, bags and all, on the part.

There is alſo a ſort of dry *fomentation*, being bags filled with medicines, but not boiled, only ſometimes ſprinkled with a little wine or brandy.

FOMENTATIONS, *ſimple*, are thoſe made with luke-warm water, milk, oil, oxycrate, or the like liquors.

Fomentations, are alſo called *local baths*, or partial bathings; becauſe, being applied on a diſeaſed part, they have much the ſame effect as a bath, or half-bath, has on the whole body.

Fomentations have different names, according to the preparations of which they conſiſt, and the uſes to which they are applied. Thus, the anodyne *fomentation*, uſed for relieving acute pain, is compoſed of white poppy-head, two ounces; elder flowers, half an ounce; which are boiled in three pints of water till one pint is evaporated, and then the liquor is ſtrained out: the aromatic *fomentation* is prepared by boiling half an ounce of Jamaica pepper in a pint of red wine for a little while, and ſtraining out the liquor: this is uſed both for external and internal complaints. Colica and diſorders of the bowels are often abated by fomenting the abdomen and region of the ſtomach with this warm liquor. The common *fomentation* is made by ſlightly boiling the dried tops of wormwood and camomile flowers, of each two ounces, in two quarts of water, and pouring off the liquor, to which may be added ſuch quantities of brandy or ſpirit of wine as the particular caſe may require. The emollient *fomentation* conſiſts of one ounce of camomile flowers; elder flowers, and ſweet fennel ſeeds, of each half an ounce; boiled for a little while in two quarts of water, and ſtrained, with the addition of ſpirit of wine, &c.

The ſtrengthening *fomentation* is prepared of oak-bark, one ounce; granate, peel, half an ounce; alum, two drams; and ſmith's forge water, three pints: the water is boiled with the bark and peel till one third is conſumed, and in the remaining decoction, ſtrained, the alum is to be diſſolved. This aſtringent liquor may be applied to foment weak parts, and alſo uſed internally.

FONCEAU, in the *Manege*, is the bottom or end of a cannon-butt-mouth; that is; the part of the bitt that joins it to the barquet. See CHAPERON.

FONGITES, a name given by the writers of the middle ages to a ſtone famous for its imaginary virtues. Authors are very vague in their deſcriptions of it; ſome deſcribing it as pellucid and colourleſs, like cryſtal; others, as opake and of a flame-colour; and ſome ſay, that it was partly of one and partly of the other of theſe colours. It is ſaid to mitigate pain, on being held for ſome time in the hand.

FONT, or *baptiſmal* FONT, a ſtone or marble veſſel, at the lower-end of a pariſh-church, ſerving to hold water to be uſed in adminiſtering the ſacrament of baptiſm.

A baptiſmal

A baptiſmal *font* was anciently the character of a pariſh church.

Its place, at preſent, is at the bottom of the church, or in a little chapel within the church. Anciently it was placed in a little church, diſtinct from the great one, though near to it, called the BAPTISTERY.

By the eighty-firſt canon it is required, that there ſhall be a *font* of ſtone in every church and chapel, where baptiſm is to be adminiſtered, the ſame to be ſet in the ancient uſual places; in which only *font* the miniſter ſhall baptize publicly.

FONT, in the *Art of Printing*, denotes a complete aſſortment of letters, accents, &c. uſed in printing. See FOUNT.

FONTANELLA, in *Anatomy*, imports the quadrangular aperture found betwixt the os frontis, and oſſa ſincipitis, in children juſt born; which is alſo called *fons pulſatilis*.

FONTEVRAUD, or FRONTEVAUX, *order of*, in *Eccleſiaſtical Hiſtory*, a religious order inſtituted by Robert d'Arbriſſel, about the latter end of the eleventh century, and taken under the protection of the holy ſee by pope Paſchal II. in 1106, and confirmed by a bull in 1113, and inveſted by his ſucceſſors with very extraordinary privileges. The chief of this order is a female, who is appointed to inſpect both the monks and nuns. The order is divided into four provinces, which are thoſe of France Aquitaine, Auvergne, and Bretagne, in each of which they have ſeveral priories. Boyle.

FONTICULUS, or FONTANELLA, in *Surgery*, a general name for ISSUES, SETONS, and the like other ſmall artificial diſcharges.

The word is a diminutive of *fons*, *fountain*, or *ſpring*.

FONTINALIA, or FONTANALIA, in *Antiquity*, a religious feaſt, held among the Romans, in honour of the deities who preſided over fountains, or ſprings. Varro obſerves, that it was the cuſtom to viſit the wells on thoſe days, and to caſt crowns into fountains. Scaliger, in his conjectures on Varro, takes this not to be a feaſt of fountains in general, as Feſtus inſinuates, but of the fountain which had a temple at Rome, near the Porta Capena, called alſo *Porta Fontinalis*: he adds, that it is of this fountain Cicero ſpeaks in his ſecond book De Legib. The *fontinalia* were held on the 13th of October.

FONTINALIS, in *Botany*, the name of a genus of moſſes of the *cryptogamia* claſs; the characters of which are theſe: the capſules are ſeſſile, or have either no pedicles, or extremely ſhort ones; they are not naked as in the ſphagna, but are covered with calyptræ, and are included beſides in a membranous huſk, by which laſt particular they are diſtinguiſhed from the hypnums, bryums, and other moſſes which produce capſules. *Tab.* XIV. *Botany*, N° 9.

There are only five known ſpecies of this genus. Linnæus enumerates only four ſpecies. Dillen. Hiſt. Moſc. p. 256.

FOOD, or ALIMENT, is whatever matter is taken in at the mouth, digeſted in the ſtomach, and other viſcera and converted into the matter of the body, to repair or ſupply what is ſpent, or wanting.

The operations which the *food* undergoes, before it becomes a part of our body, are, 1. Maſtication. 2. Deglutition. 3. Concoction. 4. Chyliſication. 5. Sanguification. 6. Aſſimilation.

Food is of two kinds, viz. *eſculents*, or *meat*; and *potents*, or *drink*.

The firſt *foods* of our great forefathers were water, and the ſpontaneous productions of the earth; with which alſo many whole nations ſuſtain themſelves to this day.

The variety of *foods*, it ſeems, does not make any difference in the ſubſtance, or actions, of the bodies ſuſtained thereby; the viſcera having a power of altering and aſſimilating them, however heterogeneous, into one ſimilar ſubſtance, like themſelves.

The difference in *foods* conſiſts principally in this: that ſome are more eaſily digeſted, and aſſimilated than others; and that ſome afford more nutritious juice than others: and to this end it is, that the divers kinds of dreſſings have been invented, viz. to diſpoſe the matter for a more eaſy and plentiful aſſimilation.

The beſt, moſt ſimple, and light of digeſtion, are, the *foods* prepared of frumentaceous and leguminous ſeeds; as wheat, rye, barley, oats, and maize, dried, ground, fermented, baked, &c. peas, beans, vetches, &c. alſo green plants, and pot-herbs; as lettuce, beet, parſley, &c. fruits, as apples, pears, berries, plums, cherries, &c. and the lean parts of animals, birds, fiſhes, inſects, &c. prepared by boiling, baking, ſtewing, &c.

And yet, for different intentions, different kinds of *foods* are required. Thus hard, dry, thick, heavy, feculent *foods*, are beſt for thoſe whoſe viſcera are ſtrong, digeſtion quick, &c. and ſoft, light, humid, ſimple *foods*, to ſuch are pernicious. Again, to the weak, valetudinary, ſtudious, and ſedentary, theſe *foods* are beſt, which are either by art, or nature, the neareſt to chyle; as milk, broths, &c. Where the temperature inclines to acidity, there alcalious *foods* are the more ſuitable; and acids, where the conſtitution inclines to be alcaline.

Some will have it, that iron, metals, minerals, &c. may by a proper preparation, become *food*; on which account decoctions of gold, chalybeats, &c. are extolled: but, it is certain, that no ſuch matters can ever be aſſimilated, and become part of our body; they may act, indeed, on the blood, and the blood-veſſels, by their weight, impetus, &c. and, on that account, may be of uſe in medicine, but not as *food*.

A due regulation of the quantity and quality of our *food*, and a nice adjuſtment thereof to the concoctive powers, would be of the utmoſt conſequence to health and long life.

What we expend in motion, exertion, effluvia, &c. is but a determinate quantity; and the ſupply ſhould only keep pace with the expence: a juſt proportion of the two would, probably, preſerve us from acute diſtempers, as it certainly would from chronical ones; moſt, or all of which proceed from repletion, as appears from their being cured by evacuation.

The qualities of *food*, as to eaſineſs, or difficulty, of digeſtion, Dr. Cheyne thinks, may be determined, in all caſes, from theſe three principles:

1. That thoſe ſubſtances which conſiſt of the groſſeſt parts, are hardeſt of digeſtion; becauſe their conſtituent parts touch in the moſt points, or have the greateſt quantity of contact, upon which their coheſion depends.

2. That thoſe ſubſtances whoſe parts are brought together with greater force, cohere proportionally cloſer, and are the more difficultly ſeparated.

3. That ſalts are very hard to be digeſted; becauſe united by plane ſurfaces, under which they are always comprehended; hence, in the laſt ſtages of the circulation, where it is ſlower, they readily ſhoot into larger cluſters, and ſo are hard to be driven out of the habit.

From theſe principles that author infers, that ſuch vegetables and animals as come ſooneſt to their growth, are eaſier of digeſtion than thoſe long in attaining to maturity; the ſmalleſt of their kind, ſooner than the larger; thoſe of a dry, fleſhy, and fibrous ſubſtance, ſooner than the oily, fat, and glutinous; thoſe of a white colour, ſooner than thoſe of a redder; thoſe of a ſoft, mild, and ſweet, ſooner than thoſe of a rich, ſtrong, poignant, aromatic taſte; land animals, than ſea animals; animals that live on light vegetable *food*, than thoſe on hard and heavy *food*; plain dreſſed *food*, than what is pickled, ſalted, baked, ſmoked, or otherwiſe high ſeaſoned; and boiled meat ſooner than roaſt, &c.

The ſame author adds, that abſtinence and exerciſe muſt concur with the due *food* for the preſervation of health; and that where exerciſe is wanting, as in ſtudious perſons, the defect muſt be ſupplied by abſtinence. See DIET.

Phyſicians have attempted to determine the healthful quantity of *food* for a human body. Some ſay, that in winter, where the perſpiration of an unexercited perſon is only equal to the urine, the diet for twenty-four hours ought not to exceed four pounds, or four pounds and a half. In ſummer, the diet may be ſix pounds and a half, which may be carried off without the help of exerciſe, when the air is hot and dry.

Dr. Bryan Robinſon thinks, that if the quantity of *food* be ſuch as to make the perſpiration and urine of a natural day always nearly equal, and the morning weight of the body always nearly the ſame, that quantity is the truly healthful quantity of *food* for grown bodies, which uſe but little exerciſe.

The quantity of *food* neceſſary to keep a grown body in health, will be better and more eaſily digeſted, when it is ſo divided as to make the meals equal, than when they are very unequal. The diſtance between one meal and another ſhould bear ſome proportion to the largeneſs of the preceding meal.

The ſame author thinks, that good and conſtant health conſiſts in a juſt quantity of *food*, and a juſt proportion of the meat to the *drink*; and that to be freed from chronical diſorders contracted by intemperance, the quantity of *food* ought to be leſſened, and the proportion of the meat to the drink increaſed more or leſs, according to the greatneſs of the diſorders; and that both the quantity of *food*, and the proportion of meat to drink, ought to be ſuch as ſhall make perſpiration and urine nearly equal at all ſeaſons of the year. See his Diſſert. on the Food and Diſcharge of Human Bodies, p. 6.

FOOD *of plants*. What is generally underſtood by this term is ſuch matter, of whatever kind, as being added and united to the firſt ſtamina of plants or plantulæ, at their ſowing, or to their roots, and thence to their trunks and other parts afterwards, gives them their increaſe, or, in other words, is itſelf the matter of that increaſe. The

great art of the husbandman is the giving this *food* to plants, in the beſt manner, and to the greateſt advantage. But before he can expect to arrive at any true knowledge in this article, it is neceſſary that he ſhould know what this *food* or matter of nouriſhment is. There are five things generally allowed to contribute to the growth and increaſe of plants; theſe are nitre, water, air, fire, and earth; but it has been much diſputed which of all theſe it is that increaſes, or is properly the *food* of the plant. Many people *buy* much of the acid ſpirit reſiding in the air; but as this is ſharp enough to corrode iron bars, it is too ſharp to be fit for nouriſhing tender plants. As to nitre, it is ſaid to nouriſh them; but its true office is not actually nouriſhing, but preparing other things to nouriſh them. Nitre applied to the root of a plant will kill it; but at a diſtance, ſo attenuates, cuts and divides the viſcous matters found in the earth, that after this they are fit to nouriſh plants, though they were not ſo before. Water has been thought by ſome the only *food* of plants; but Van Helmont's famous experiment, uſually brought to prove this, is nothing, for the water contains earth, and therefore never given to a plant as water alone.

Air, becauſe of its elaſticity, is neceſſary to the increaſe of plants, but is is not that increaſe, though Bradley and others have taken great pains to prove that it is ſo. As to fire, we are very well aſſured indeed, that no plant can live without heat; but though different degrees of it are neceſſary to different plants, yet none can live in actual fire; nor has fire ever been thought the food of plants except by Mr. Lawrence, and ſome of the metaphyſicians. This author indeed ſays, plants are true fire-eaters, and others explain away the meaning of the phraſe by defining that fire to be only the minuteſt particles of earth put in motion; if this be the caſe, probably enough the doctrine may be true. But as ſome have maintained, earth alone is the true food and matter of increaſe of plants. Every plant, they ſay, is earth, and the growth and increaſe of that plant is only the addition of more earth to it, in the ſame form. Nitre and other ſalts, as thoſe of dung, &c. prepare, attenuate, and divide the earth, deſtined for the increaſe of vegetables; water and air move it by conveying, and fermenting it in the juices: but earth itſelf ſtill is the *food*. When the additional earth is once aſſimilated to the plant, it becomes a part of it, and remains for ever with it; but let water, air, and heat, be taken away, and the plant remains a plant ſtill, though a dead one.

The exceſs of the other things proves, that they are not the proper *food* of the plant, by deſtroying not nouriſhing it. Too much nitre or other ſalts corrode and kill the plant, too much water drowns it, too much air dries the roots of it, too much heat burns it; but too much earth a plant can never have, unleſs wholly buried under it, ſo as to exclude the neceſſary action of the reſt of the aſſiſtant articles. See PLANTS.

FOOL, according to Mr. Locke, is one who makes falſe concluſions from right principles; by which he is diſtinguiſhed from a madman. See FOLLY.

Dr. Willis relates, that, upon diſſecting a *fool*, the principal differences found between him and a man of ſenſe, were, that the brain was ſmaller; and that the cervical plexus, formed of the intercoſtal nerve, whereby the correſpondence between the brain and heart is effected, was leſs, and ſent forth fewer branches to the heart, &c. Nervor. Deſcript. & Uſ. cap. 26.

FOOL's *ſtones*, in *Botany*. See ORCHIS.

FOOT, a part of the body of moſt animals, whereon they ſtand, walk, &c.

Animals are diſtinguiſhed, with reſpect to the number of *feet*, into bipedes, q. d. *two-footed*; ſuch are men and birds; quadrupedes, q. d. *four-footed*; ſuch are moſt land animals; and multipedes, q. d. *many-footed*; as inſects. The reptile kind, as ſerpents, &c. have no feet.

Lobſters have twelve *feet*; ſpiders, mites, and polypuſes, eight; flies, graſhoppers, and butterflies, have ſix *feet*.

Galen has ſeveral good obſervations on the wiſe adjuſtment of the number of *feet* in men and other animals, in his book De Uſu Part. lib. iii.

The *fore-feet* of the mole are admirably formed to dig, and ſcratch up, the earth, and make way for its head, &c. in water fowls, the legs and *feet* are excellently adapted, to their reſpective occaſions, and manners of living; in ſuch as are to wade in rivers, the legs are long, and bare of feathers a good way above the knee; their toes alſo are broad; and in ſuch as bear the name of *ſwimmers*, two of the toes are ſomewhat elated, that they may not eaſily ſink in walking upon boggy places.

Others, which are to ſwim, are *web-footed*; i. e. have their toes webbed together; as in the gooſe, duck, &c. and it is pretty enough to obſerve, how artfully theſe will gather up their toes and *feet*, when they withdraw their legs, or go to take their ſtroke in ſwimming; and again expand, or open, the whole *foot*, when they preſs upon, or drive themſelves forward in the water.

FOOT, in *Anatomy*. The *great foot* denotes the whole extent from the jointure of the hip to the tip of the toes; as the great hand does the whole from the ſhoulder to the fingers ends.

The *pes magnus*, or *great foot*, is divided into the thigh, the leg, and the *foot* properly ſo called.

Its bones are, the femur, or thigh-bone; the TIBIA, the PATELLA, and FIBULA, for the leg; and thoſe of the *tarſus*, *metatarſus*, and toes.

Its arteries are branches of the crural artery, and its veins terminate in the crural vein. Of theſe there are five principal ones; viz. the SAPHENA, great and little iſchiadic, the MUSCULUS, POPLITEA, and SURALIS.

FOOT, properly ſo called, or the *leſſer foot*, denotes only the extremity of the leg, conſiſting of three parts; viz. the *tarſus*, the ſpace from the ankle to the body of the *foot*, anſwering to the wriſt in the hand; *metatarſus*, the body of the *foot* to the toes; and *digiti*, or toes. Each of theſe parts conſiſt of a great number of bones; as the *calx*, *talus*, *cuneiformis*, and *cuboides*. The bottom of all is called the ſole, or *planta pedis*. See TALUS, &c.

FOOT, *cartilages of the*. The *aſtragalus* is covered by three cartilages; the firſt covers the three ſurfaces which make the convex part and ſides of the pulley; the ſecond the concave ſurface of its inferior part, and the third the convex ſurface of its inferior part, being continued over the inferior part, ſo far as to form three other ſmall ſurfaces; one of which is not articular in a ſtrict ſenſe. The firſt of theſe cartilages is for the articulation of this bone with the *tibia* and *fibula*, the ſecond for the *os calcis*, and the third for the *os ſcaphoides*; two of the inferior ſurfaces formed by the continuation of the third cartilage, are for the articulation of this bone with the *os calcis*; and the third contributes to the formation of a channel for the paſſage of a tendon.

The *os calcis* has four cartilages, of which three are ſuperior, one large, and two ſmall, for its triple articulation with the *aſtragalus*; the fourth is anterior for the *os cuboides*. And to theſe muſt be added a ſmall thin cartilage of a kind of ligamentary ſubſtance, under the tubercle, on the outſide of this bone. The *os ſcaphoides* has two cartilages; one poſterior, for its articulation with the *aſtragalus*, and one anterior, divided into three parts for the three *oſſa cuneiformia*.

The *os cubides* has two remarkable cartilages, one poſterior, for its articulation with the *os calcis*; the other anterior, lying in two planes, for its articulation with the two laſt metatarſal bones; it has likewiſe a cartilage on the inſide for the *os cuneiforme*, which is next to it, and one on the lower part, covering an oblique eminence ſituated there.

The three *oſſa cuneiformia* have each of them a poſterior cartilage for their articulation with the *os ſcaphoides*, and one anterior for the three firſt metatarſal bones; they have likewiſe ſmall cartilaginous ſurfaces on their lateral ſides for their articulation with each other; and beſides, the firſt and third bones are joined thereby to the lateral parts of the baſis of the ſecond metatarſal bone, and the third to the *os cubiides*. The baſes and heads of the metatarſal bones are covered with cartilages. The phalanges alſo have, in the ſame manner, cartilages at their baſes and heads, except at the heads or extremities of the laſt. The ſeſamoide bones are covered with cartilages on that ſide, by which they ſlide on other bones; but great caution is required not to confound the remains of tendons, ligaments, and aponeuroſes, with the true cartilages, particularly on the poſterior part of the *os calcis*. Wiſlow's Anatomy, vol. i. p. 132, &c.

FOOT, *ligaments of the*. The *foot* being made up of many bones, muſt neceſſarily, beſides thoſe ligaments, by which it is tied to the bones of the leg, have ſeveral others to connect not only the three parts of which it is compoſed, but alſo the particular bones of each part to one another. In each ankle there are three ligaments for their articulations with the *foot*; one anterior, one middle, and one poſterior. The ligaments of the inner ankle are all tied to the inſide of the *aſtragalus*; the anterior and middle ligaments of the outer ankle are more or leſs broad, and are fixed on the outſide of the *aſtragalus*; the poſterior, which is the narroweſt, and pretty thick, is chiefly fixed in the outſide of the great portion of the *os calcis*. All theſe ligaments lie on the outſide of the capſula, which ſurrounds the articulation of the *aſtragalus* with the bones of the leg. The ligaments by which the bones of the tarſus are connected to one another, are ſhort, fat, of different breadths, and run from one bone to another, in different directions. Some of theſe are common to ſeveral bones, and others belong only to two. The *aſtragalus* is tied to the other bones of the tarſus by ſeveral true ligaments; to the inſide of the *os calcis*, by one

which comes from the lateral *apophysis* of the *os calcis*, in an inequality on its hinder part, and is fixed again to the posterior internal tuberosity of the body of the *astragalus*, to the outside of the same bone, by two ligaments which come from the edge of the oblique inferior depression of the *astragalus*, and afterwards separating a little, are fixed in the outside of the great *apophysis* of the *os calcis*, one forward, which seems to send off a small portion to the *os cuboides*, and the other backward, of different breadths; to the *os scaphoides* superiorly by a ligament, which goes from the neck of the *astragalus*, to the upper part of that bone, and from thence is extended to the middle of the *os cuneiforme*; to the same bone internally by two ligaments, one of which is a continuation of that which goes from the lateral *apophysis* of the *os calcis* to the cartilaginous production of the *astragalus*; the other is near the same production, being partly covered by the former, and fixed in the tuberosity of the *os scaphoides*; to the *os calcis*, by a ligament which comes from the oblique inferior depression of the *astragalus*, and is fixed in the oblique superior depression of the *os calcis*; and to these, the principal ligaments of the *astragalus*, several smaller may be added, which are usually seen, and increase the number very greatly.

The capsular ligaments go very little farther than the edges of the articulations of this bone with the rest; they adhere very closely to the true ligaments, and are covered and hid by them. The *os calcis* is connected to the *os scaphoides*, by a continuation of the ligament that goes from its lateral internal *apophysis* to the cartilaginous production of the *astragalus*, by a ligamentary plane, which goes from its great *apophysis*, to the inferior part of the *scaphoides*; and by a narrower ligament, which goes from the superior internal part of its great *apophysis*, and ends in the nearest part of the circumference of the *scaphoides*. It is connected to the *os cuboides* by several ligamentary *fasciculi*, which go from its extremity in its superior oblique depression, to the contiguous angle of the *os cuboides*; by one from near the lateral external tuberosity of the *os calcis*, to a part of the *cuboides* near the former; by one fixed to the exterior and inferior part of the great *apophysis* of the *os calcis*, to the contiguous part of the *cuboides*; by a pretty broad plane, which covers the inferior part of the *os calcis*, and ends in the oblique eminence of the *cuboides*; and by a broader plane, which filling the lower part of the lateral concavity in the *os calcis*, is chiefly inserted in the contiguous angle of the *os cuboides*. The capsular ligaments agree with those of the *astragalus*.

The *os scaphoides* is tied to the *os cuboides* on its outside by one ligament, which connects it to the contiguous angle of that bone: on its upper part two go from it to the second and third *ossa cuneiformia*; on its interior side it is joined to the convex side of the great *os cuneiforme* by two ligaments, and on its lower, it has four; the first appears double, and goes from the tuberosity of this bone to the basis of the first *os cuneiforme*; the second and third go obliquely to the second and third *os cuneiforme*; and the fourth is a little transverse, being fixed in the inferior internal angle of the *os cuboides*.

The *os cuboides*, beside those already described, has ligaments which tie it above, below, and on the outside, with the third *os cuneiforme*, and the two last bones of the metatarsus; the superior ligaments are almost equally flat, the inferior irregularly thick, and stronger than the superior. The three *ossa cuneiformia* are connected together on their upper part by particular ligamentary planes, which go more or less transversely, from one bone to another, being all joined to one common ligamentary plane which covers those three bones, and also the *os cuboides*; they are also connected by ligaments to the three first bones of the metatarsus.

The bones of the metatarsus are connected together by their bases and heads; the ligaments which go between the bases are superior and inferior: the superior small and flat, the inferior strong and thick. Those between their heads have nearly the same disposition, but the inferior have this peculiar to them, that by filling up the spaces between the heads, they keep them at some distance from one another; the inferior portions are fixed in the angles at the lower part of each head, and are strengthened by their union and intertexture with the *aponeurosis plantaris*. Winslow's Anatomy, vol. i. p. 134, &c.

Feet, *bathing of the*. The uses of warm bathing in general, and of the *pediluvium* in particular, are so little understood, that they are often prepostcrously used, and sometimes as injudiciously abstained from.

In the Medical Essays of Edinburgh, we find an ingenious author's opinion of the warm *pediluvium*, notwithstanding that of Borelli, Boerhaave, and Hoffman, to the contrary, to be, that the legs becoming warmer than before, the blood in them is warmed; this blood rarefying, distends the vessels; and in circulating imparts a great degree of warmth to the rest of the mass; and a there is a portion of it constantly passing through the legs, and acquiring new heat there, which heats, in the course of circulation, communicated to the rest of the blood; the whole mass rarefying, occupies a larger space, and of consequence circulates with greater force. The volume of the blood being thus increased, every vessel is distended, and every part of the body feels the effects of it; the distant parts a little later than those first heated. The benefit obtained by a warm *pediluvium* is generally attributed to its making a derivation in the parts immersed, and a revulsion from those affected, because they are relieved: but the cure is performed by the direct contrary method of operating, viz. by a greater force of circulation through the parts affected, removing what was stagnant, or moving too sluggishly there. Warm bathing is of no service where there is an irresoluble obstruction, though, by its taking off from a spasm in general, it may seem to give a moment's ease; nor does it draw from the distant parts, but often hurts by pushing against matter that will not yield with a stronger impetus of circulation than the stretched and diseased vessel can bear; so that where there is any suspicion of scirrhus, warm bathing of any sort should never be used. On the other hand, where obstructions are not of long standing, and the impacted matter is not obstinate, warm baths may be of great use to resolve them quickly. In recent colds, with slight humoral peripneumonies, they are frequently an immediate cure. This they effect by increasing the force of the circulation, opening the skin, and driving freely through the lungs that texture which stagnated or moved slowly in them. As thus conducing to the resolution of obstructions, they may be considered as short and safe fevers; and in using them we imitate nature, which by a fever often carries off an obstructing cause of a chronical ailment. Borelli, Boerhaave, and Hoffman, are all of opinion, that the warm *pediluvium* acts by deriving a larger quantity of blood into the parts immersed. But arguments must give way to facts: the experiments related in the Medical Essays seem to prove to a demonstration, that the warm *pediluvium* acts by rarefying the blood.

A warm *pediluvium*, when rightly tempered, may be used as a safe cordial, by which circulation can be roused, or a gentle fever raised; with this advantage over the cordials and sudorifics, that the effect of them may be taken off at pleasure. Med. Ess. Edinb. abr. vol. i. p. 237, &c.

Pediluvia are sometimes used in the small-pox; but Dr. Stevenson thinks their frequently tumultous operations render it at best of very doubtful effect; and he therefore prefers Mons. Martin of Lausanne's method of bathing the skin, not only of the legs, but of the whole body, with a soft cloth, dipped in warm water, every four hours, till the eruption; by which means the pustules may become universally higher, and consequently more safe. Med. Ess. abr. ib. p. 248.

Foot, *bleeding in the*. Bleeding in the *foot* is an operation of very old standing, and has been used by the oldest physicians, for disorders of the head and breast, and for obstructions of the menstrual, and habitual discharges by the hæmorrhoidal veins. It has been of old supposed, that the bleeding from the saphæna was more particularly serviceable in some cases, and from the cephalica in others; but this is now known to be highly erroneous, and the surgeon is always to take that which lies fairest and most conspicuous. If the veins on the metatarsus or instep do not appear so fairly as might be wished, it is common to take one of those about the ankle, or the calf of the leg or ham.

The patient to be bled in the *foot*, must first keep both *feet* some time in warm water, that the veins may become turgid, and the surgeon have his choice which he will take. Having fixed upon the proper *foot*, the ligature must be made about two fingers breadth above the ankle, and the patient must then return the *foot* into water. The surgeon is to kneel on one knee, and having wiped the *foot* dry, to put it either against his other knee, or upon a board placed over the vessel of hot water, and the vein must be held secure from slipping away, with the left hand, while the orifice is made with the other. If the blood does not flow freely, the *foot* must be returned into the warm water, till by the colour of the water, strength of the patient, &c. it is found to have bled enough. Heister's Surgery, p. 280.

Feet, *fractures of the*. The bones of the *foot* which compose the tarsus, the metatarsus, and toes, are equally liable to fractures with the other bones, but on account of the great complication of nerves, tendons, ligaments, and membranes, fractures in this part are usually attended

ed with very bad symptoms. The bones are carefully to be replaced and secured by bandage; but fractures of the *foot*, like those of the hands, can seldom be so perfectly cured, as not to leave a ſtiffneſs or want of motion behind; if the patient ſhould be ſo happy as to eſcape ulcers, caries, or incurable fiſtulæ. Theſe bad ſymptoms when they appear in the courſe of the cure, are no way to be remedied but by the amputation of the limb; nor will that indeed always ſecure the patient from death. Heiſter, p. 138.

Dr. Walther has given a minute deſcription of the muſcles and ligaments of the ſole of the *foot*, in the Nova Act. Eruditor. Lipſ. April, 1732.

FOOT, in the *Manage*, is the extremity of a horſe's leg, from the corner to the lower part of the hoof. The four *feet* are diſtinguiſhed by four different names; the two *fore-feet* are by ſome called the hands of a horſe; but that term is in diſuſe, the common expreſſion being the *fore fore-foot*, to denote the right *foot* before; and the *near fore-foot*, the *ſiniſtro-foot*, and the *bridle hand-foot*, to denote the left *foot* before.

Of the two hinder *feet*, the right is called the *far hinder-foot*; and when ſpears were uſed, it was called the *ſpear-foot*, becauſe in reſting the ſpear, the ſocket of it anſwered the right hinder *foot*. The left hind *foot* is called the *near foot behind*.

FOOT-*dorſe*, in the *Manage*. A horſe's *foot* has this appellation when it is worn and waſted by going without ſhoes, ſo that for want of a hoof, it is a hard matter to ſhoe him.

A horſe's *foot* is ſaid to be worn and waſted, called in French *uſé*, when he has but little hoof, and not enough for ſhoeing.

FOOT, *to poliſh upon a good*, or put a horſe upon a good *foot*, called in French *ſur le bon pied*. See *Falſe* GALLOP.

FOOT, *fat*, in the *Manage*. A horſe is ſaid to have a *fat foot*, when the hoof is ſo thin and weak, that unleſs the nails be driven very ſhort, he runs the riſque of being pricked in ſhoeing. The Engliſh horſes are very ſubject to this diſorder.

FOOT, in the *Military Art*, is uſed for *foot* ſoldiers, or the INFANTRY of an army.

FOOT, in the *Greek* and *Latin Poetry*, denotes a metre, or meaſure, compoſed of a certain number of long and ſhort ſyllables.

The ſpondee, iambic, trochee, and pyrrhic, are diſyllabic *feet*; i. e. they conſiſt of two ſyllables each; the dactyl, anapeſt, moloſſus, tribrach, bacchius, antibacchius, amphibrachys, and creticus, are triſyllabic, or conſiſt of three ſyllables each; the proceleuſmaticus, choriambus, and epitrite, are quadriſyllabic, or compoſed of four ſyllables. See each under its proper head, SPONDEE, IAMBUS, &c.

There are alſo other *feet*, invented by grammarians, of five, ſix, or more ſyllables; but they are not worth the reciting.

Hexameter verſes conſiſt of ſix *feet*; pentameters, only of five.

FOOT, *even* and *odd*, par and impar. In poetry, and particularly, in iambic verſes, *feet* are denominated *odd* and *even*, in reſpect of their ſituation in the verſe. Thus, the firſt, third, and fifth, *foot* of the verſe, are uneven; becauſe thoſe numbers are not capable of being divided into two equal parts.

In the ancient tragedy, the iambic verſes, which prevailed therein, only allowed uneven *feet* to the ſpondees; ſo that the ſecond, the fourth, and ſixth *feet*, were to be iambics, becauſe they were even. This regular mixture of ſpondees in the uneven *feet*, rendered the verſe the more ſolemn and noble.

The comic poets, the better to diſguiſe their verſe, and make it more like proſe, took the contrary courſe; putting ſpondees, where the tragic poets would only have allowed iambics.

FOOT is alſo a long meaſure, conſiſting of twelve inches.

The *foot* long is divided into twelve inches, and the INCH into barley-corns.

Geometricians divide the *foot* into ten digits, and the digit into ten lines, &c.

The French divide their *foot*, as we do, into twelve inches; and the inch into twelve lines.

The *foot* ſquare is the ſame meaſure, both in length and breadth, containing 144 ſquare, or ſuperficial inches.

The cubic, or ſolid *foot*, is the ſame meaſure in all the three dimenſions, containing 1728 cubic inches.

The *foot* is of different lengths, in different countries. The Paris royal *foot* exceeds the Engliſh by nine lines and a half; the ancient Roman *foot* of the Capitol conſiſted of four palms, equal to eleven inches and ſeventenths Engliſh; the Rhineland, or Leyden *foot*, by which the northern nations go, is to the Roman *foot*, as 950 to 1000. The proportions of the principal *feet* of ſeveral nations, compared with the Engliſh and French, are here ſubjoined.

The Engliſh *foot* being divided into one thouſand parts, or into twelve inches, the other *feet* will be as follow:

		Th. Pts.	F.	Inch.	Li.
London - -	Foot	1000	0	12	0
Paris foot, the royal, by Greaves		1068	1	0	9.7
Paris foot, by Dr. Bernard		1066	1	0	1
Paris foot, by Graham, from the meaſure of half the toiſe of the Chatelet, the toiſe containing ſix Paris feet -		1065.413			
By Mounier, from the ſame data - - -		1065.351

Roman *foot*, from the monument of Ceſſutius in Rome, by Greaves - - -		967			
From the monument of Statilius, by the ſame - -		972			
Of Vitruvius Pandus, deduced from the congius of Veſpaſian		986			

Mr. Riper, who has induſtriouſly collected a variety of authorities relating to the meaſure of the old Roman *foot*, determines the mean to be nearly 968 thouſandth parts of the London *foot*. And by an examination of the ancient Roman buildings in Deſgodetz's Edifices Antiques de Rome, Paris, 1682, he concludes, that the Roman *foot* before the reign of Titus exceeded 970 parts in 1000 of the London *foot*; and in the reigns of Severus and Diocleſian fell ſhort of 965. Phil. Tranſ. vol. li. art. 69. p. 774, &c.

The Paris *foot* being ſuppoſed to contain 1440 parts, the reſt will be as follow:

Paris - -	Foot	1440
Rhineland - - -	Foot	1391
Roman - -	Foot	1320
London - -	Foot	1350
Swediſh - - -	Foot	1320
Daniſh - -	Foot	1403
Venetian - - -	Foot	1546⅔
Conſtantinopolitan -	Foot	3120
Bononian - -	Foot	1682⅔
Strafbourg - -	Foot	1382⅔
Norimberg - -	Foot	1346⅔
Dantzick - -	Foot	1721⅓
Hall - -	Foot	1320

In Scotland, this MEASURE of length, though conſiſting of twelve inches, exceeds the Engliſh *foot*, ſo that 185 of the former is equal to 186 of the latter.

FOOT-*bank*, or FOOT-*ſtep*, in *Fortification*. See BANQUETTE.

FOOT *of the foreſt*, *pes foreſtæ*, in our *Ancient Cuſtoms*, contained 18 inches, or 1½ of the common *foot*.

Notandum eſt, quod pes foreſtæ *uſitatus tempore Ric. Oyſell, in arrentatione vaſtorum, fallus eſt, ſignatus & ſculptus in portiis cancellis eccleſiæ de Edwyneſtone, & in eccleſia Beatæ Mariæ de Nottingham: Et dicitur* pes *continet in longitudine octodecim pollices, &c.* Ex Regiſt. Abb. de Novo. Loco in Com. Nott.

FOOT, *fore*. See FORE-*foot*.

FOOT-*geld* was an ancient amerceement, for cutting out the balls of the feet of great dogs in the foreſt; to prevent their running after the king's deer.

FOOT-

FOOT-*guard*. See GUARDS.

FOOT-*hooks*, in a *Ship*. See FUTTOCKS.

FOOT, *hexam*. See *Univerſal* MEASURE.

FOOT-*hoſts*, among *Gardiners*, are the ſhort heads out of which flowers grow. See CALYX.

FOOT *of a ſail*, denotes the lower edge or bottom.

FOOT-*rule*, an inſtrument which ſerves to do the office both of a level, a ſquare, and a *foot* rule.

The *foot-level*, repreſented *Tab. Surveying*, *fig.* 15. conſiſts of two branches, about an inch broad; opening and ſhutting like a two-foot rule.

Theſe branches are hollowed half way up the ſide of each to receive a kind of tongue, or thin piece of braſs, which is faſtened to one of them, by means whereof the branches may be ſhut cloſe together. The uſe of this tongue is ſuch, that when the end of it is placed in the branch it is not faſtened to, where there is a pin that holds it, the two branches will ſtand at right angles; to the head of the inſtrument is likewiſe added a ſquare piece of braſs, by means whereof it does the office of a ſquare. At the bottom of the angle of the ſaid piece of braſs is a little hole, wherein is faſtened a line with a plumbet; which falling on a perpendicular line drawn on the tongue, ſhews whether any thing the inſtrument is applied to, be level or not. See LEVEL.

FOOT, *lieutenan-ſhrievel of*. See LIEUTENANT.

FOOT-*pace*, *half-pace*, or *landing-place*. See STAIR-*caſe*.

FOOT-*rule*. See RULE.

FOOT-*ropes*, are thoſe to which the *foot* of the ſail is ſewed. They are alſo the ſame with the horſes of the yards. See HORSE.

FOOT-*walling*, denotes the whole inſide planks or lining of a ſhip, uſed to prevent any part of the ballaſt or cargo from falling between the floor-timbers.

FOP, probably derived from the *ſuppa* of Horace, applied in the firſt ſatire of his firſt book to the wild and extravagant Nævius, is uſed among us to denote a perſon who cultivates a regard to adventitious ornament and beauty to exceſs.

FORAGE. See FORRAGE.

FORAMEN, in *Anatomy*, a name given to certain holes, or perforations, in divers parts of the body: as the

FORAMEN *auditorium internum*, which is ſituate in the backſide of the *apophyſis petroſa*, in ſome meaſure behind the *veſtibulum* and baſis of the *cochlea*. It is a kind of blind hole divided into two foſſulæ, one large, the other ſmall; the large one lies loweſt, and ſerves for the *portio mollis* of the auditory nerve, or ſeventh pair; the ſmall one is uppermoſt, and is the opening of a ſmall duct, through which the *portio dura* of the ſame nerve paſſes. The inferior foſſula is full of little holes, which in the natural ſtate are filled with nervous filaments of the *portio mollis*, which go to the ſpindle, to the ſemicircular canals, and to thoſe of the *cochlea*. It is this foſſula which forms the ſhallow cavity at the baſis of the ſpindle of the *cochlea*. The paſſage of the *portio dura* of the auditory nerve runs behind the tympanum, and its orifice is the ſtyloma ſtoide hole. Fallopius gave this duct the name of the aqueduct, from its reſemblance to the aqueducts in Italy. It begins by the ſmall foſſula, and pierces from within outwards, the upper part of the *apophyſis petroſa* making there an angle or curvature; from thence it is inclined backward behind the ſmall pyramid of the tympanum, and runs down to the ſtyloma ſtoide hole, through which it goes out. It communicates likewiſe by a ſmall hole with the ſinus of the pyramid, and lower down by another hole with the barrel of the ear. In ſome ſkulls this aqueduct of Fallopius is open on the upper part of the *apophyſis petroſa*, a kind of break appearing in it, formed by a double hole. It is at this place that it makes the angle already mentioned, but it is commonly covered with a bony lamina. Winſlow's Anat. p. 52.

FORAMEN *incarum*. See DUKA *Mater*.

FORAMEN *of the membrana tympani*, is a perforation in the membrane of the tympanum, or drum in the ear; which admits of the paſſage of wind, ſmoke, &c. from the *meatus a palato* to the drum.

This paſſage is very ſmall, and runs obliquely from the tympanum through the upper part of its membrane, near the proceſs of the malleus. The exiſtence of this perforation is more evident, when ulcers affect the palate, by the egreſs of wind upon the patient's ſtopping his noſe and mouth, and forcing the wind by the ears, than by any anatomical inſpection.

FORAMEN *ovale*, or FORAMEN *Botalli*, an oval aperture or paſſage through the heart of a fœtus, which cloſes up after birth. See *Tab. Anat. (Splanch.) fig.* 12. *let. g.*

It riſes above the coronary vein, near the right auricle; and paſſes directly into the left auricle of the heart.

The *foramen ovale* is one of the temporary parts of the fœtus, wherein it differs from an adult. It ſerves for the circulation of the blood in the fœtus, till ſuch time as the infant breathes, and the lungs are opened.

Its uſe was firſt exactly deſcribed by Leon. Botallus of Aſti in Piedmont, in the year 1562, who, tracing the courſe and paſſage of the blood, aſſerted the *foramen ovale* to be that opening whereby the blood in fœtuſes was conveyed from the right ventricle to the left.

The modern anatomiſts have admitted the diſcovery; and the *foramen ovale* is now generally allowed a part neceſſary in the ſyſtem of the circulation of the blood in the fœtus. The different hypotheſes relating to this ſubject by Harvey, Mery, and Wolf, may be found under the articles BLOOD and FŒTUS.

At the aperture of the *foramen* there is a kind of ſhutting membrane, which looks like a valve; but it has nothing of the office thereof; it does not hinder the blood from paſſing from either auricle to the other. All it ſerves for, according to Mr. Winſlow, is, to cloſe the *foramen* after the birth.

It has generally been thought, that the *foramen ovale* may ſometimes remain open, even in adults; and, in effect, divers authors furniſh us with inſtances thereof. See Phil. Tranſ. N° 460. § 5.

Dr. Connor aſſures us, he found it but half cloſed in a girl of four or five years old; and in another girl, which he opened at Oxford, there was room left to thruſt a tent through. Diſſert. Med. Phyſ. de Stup. Of. Conſ.

The accurate Mr. Cowper adds, that he has often found the *foramen ovale* open in adults. Anat. Append. *fig.* 3.

And the Paris anatomiſts obſerve, that in a ſea-calf the *foramen ovale* is always open, by which means it is enabled to ſtay ſo long under water.

Somewhat of this, too, is ſuppoſed to have been the caſe in the extraordinary recovery of divers perſons drowned, hanged, &c. See DROWNING.

But Mr. Cheſelden ventures to ſet aſide all theſe authorities; and contends, that the *foramen ovale* is neither open in any adult land-animals, nor in amphibious creatures. When he firſt applied himſelf to diſſection, he tells us, he had no diſtruſt of the frequent accounts in authors of the *foramen* being open; but he afterwards found, that he himſelf often miſtook the oſtium of the coronary veins for the *foramen*; and the like he imagines other authors to have done; who aſſert, that it is always open in amphibious animals; becauſe, upon a diligent inquiry into theſe animals, he could never find it open in any of them. Neither does he think that ſufficient to enable theſe creatures to live under water, as the FŒTUS does *in utero*; unleſs the *ductus arterioſus* were open alſo. Cheſel. Ap. Der. Phyſ. Theol. lib iv. cap. 7.

FORCE, *Vis*, or *Power*, in *Mechanics*, *Philoſophy*, &c. See VIS, and POWER.

Whenever a body, which was at reſt, begins to move, or has a motion which is either not uniform, or not direct, the cauſe of this change in the ſtate of the body is called *force*.

While a body remains in the ſame ſtate, either of reſt, or of uniform and rectilinear motion, the cauſe of its remaining in ſuch a ſtate, is in the nature of the body, and it cannot be ſaid, that any extrinſic *force* has acted on it. This internal cauſe or principle is called *inertia*.

Mechanical *forces* may be reduced to two ſorts; one of a body at reſt, the other of a body in motion.

The *force* of a body at reſt, is that which we conceive to be in a body lying ſtill on a table, or hanging by a rope, or ſupported by a ſpring, &c. and this is called by the names of *preſſure*, *tenſion*, *ſorte*, or *vis mortua*, *ſolicitatio*, *conatus movendi*, *connixus*, &c. To this claſs alſo of *forces* we muſt refer centripetal and centrifugal *forces*, though they reſide in a body in motion; becauſe theſe *forces* are homogeneous to weights, preſſures, or tenſions of any kind.

The meaſure of this *force* is the weight with which the table is preſſed, or the rope ſtretched, or the ſpring is bent; and as to this meaſure there is no diſpute, notwithſtanding the diverſity of appellations by which it is called.

The *force of a body in motion* is on all hands agreed to be a power reſiding in that body, ſo long as it continues its motion; by means of which, it is able to remove obſtacles lying in its way; to leſſen, deſtroy, or overcome the *force* of any other moving body, which meets it in an oppoſite direction; or to ſurmount any dead preſſure or reſiſtance, as tenſion, gravity, friction, &c. for ſome time; but which will be leſſened or deſtroyed by ſuch reſiſtance, as leſſens or deſtroys the motion of the body.

This is called *moving force*, *vis motrix*, and by ſome late writers *vis viva*, to diſtinguiſh it from the *vis mortua* ſpoken of before; and by theſe appellations, however different, the ſame thing is underſtood by all mathematicians, namely, that power of diſplacing, or withſtanding oppoſite moving *forces*, or of overcoming any dead reſiſtance, which reſides in a moving body, and which in whole or in part, continues to accompany it, ſo long as the body moves.

But about the measure of this sort of *forces*, mathematicians are divided into two parties. Both sides agree, that the measure of this *force* depends partly upon the mass, or weight, of the body, and partly upon its velocity; so that upon any increase of weight or velocity, the moving *force* will become greater. It is also agreed, that the velocity being given, or being the same in two bodies, their *forces* will be in proportion to their masses or weights.

But when two bodies are equal, and the velocities with which they move are different, the two parties no longer agree about the measure of the moving *forces*.

The Newtonians and Cartesians maintain, that the moving *forces* is in proportion to the velocity with which the bodies move. But the Leibnitians assert, that the moving *force* is in proportion to the square of the velocity; so that if the velocity of a moving body be double, triple, quadruple, &c. of that of another equal body, the *force* of the former will be four times, nine times, sixteen times as great as that of the latter. See Dr. Jurin, in Phil. Transf. N° 476.

Hence the Newtonians allege, that the momentum or moving *force* of bodies is in the compound ratio of their weights and velocities; and the Leibnitians, that it is in the compound ratio of their weights, and the squares of the velocities. If we allow the distinction, already stated, between the *vis viva* and the *vis mortua*, they appear, by the most familiar experiments with the balance, and other mechanical powers, to be in the simple proportion of the velocity multiplied into the mass; as pressure pounds being placed at the distance of six inches from the centre of motion of a balance, and two pounds at the distance of twelve, will have a *vis viva*, if the balance be put into a swinging motion. These *forces* appear to be equal, because, with contrary directions, they soon destroy each other; but they are to one another in the simple ratio of the velocity multiplied into the mass, viz. $4 \times 6 = 24$, and $2 \times 12 = 24$. Whereas if the *forces*, in this case, had been as the mass into the square of the velocity, the weight 2 placed at near 8½ inches would have destroyed the motion of the weight 4 at 6 inches distance, and have reduced it to an equilibrium; i. e. $6 \times 6 \times 4 = 144$; and $8.426, \&c. \times 8.426, \&c. \times 2 = 144$. With regard to the *vis mortua*, it is plain, that 2 at the distance 12 keeps 4 in equilibrio at the distance 6; and the least alteration either of weights or distance will destroy the equilibrium. Defag. Exp. Phil. vol. i. p. 393.

Though Leibnitz was the first that expressly asserted the *force* of a body in motion to be as the square of its velocity, in a paper inserted in the Leipsick Acts of the year 1686, yet Huygens has been thought to have led him into this notion, by some demonstrations in the fourth part of his book De Horologio Oscillatorio, relating to the centre of oscillation, and by his dissertations, in answer to the objections of the abbot Catelan, one of which was published in 1684. This eminent mathematician had demonstrated, that in the collisions of two bodies, perfectly elastic, the sum of the products of the bodies by the squares of their respective velocities, was the same after the shock as before; and this proposition is so far general as to obtain in all collisions of bodies that are perfectly elastic. It is also true, when bodies of a perfect elasticity strike any immovable obstacle, as well as when they strike one another; or when they are constrained by any power or resistance to move in directions different from those in which they impel one another. These considerations might have induced Huygens to lay it down as a general rule, that bodies constantly preserve their *ascensional force*, that is, the product of their mass, by the height to which their centre of gravity can ascend; and, therefore, in a given system of bodies the sum of the squares of their velocities will remain the same, and not be altered by the action of the bodies among themselves, nor against immovable obstacles. Leibnitz's metaphysical system led him to think that the same quantity of action or *force* subsisted in the universe; and finding this impossible, if *force* were estimated by the quantities of motion, he adopted Huygens's principle of the preservation of the ascensional *forces*, and made it the measure of moving *forces*. But it is to be observed, that Huygens's principle, above mentioned, is general only when bodies are perfectly elastic; and in some other cases, which Mr. Maclaurin has endeavoured to distinguish; shewing at the same time that no useful conclusion in mechanics is affected by the disputes concerning the mensuration of the *force* of bodies in motion, which have been objected to by mathematicians. Analysis, Query 9. See Maclaurin's Fluxions, vol. ii. art. 533, and preceding articles. *Hæc conclusa sunt, corpora servare vim suam ascendentem, & idcirco summum quadratorum velocitatum illorum semper manere eandem. Hic autem non solum obtinet in ponderibus pendulorum & percussione corporum duorum, sed in multis quoque mechanicis experimentis.* Huygen. Oper. tom. i. p. 228.

Huygens, p. 247. of the same book observes, *Quod sæpe perist pars motus, licet hunc in aliquo effectu admodum conjunctum, affirmare non possumus, ut in multis casibus percussionis durorum corporum—ita ut minime pro lege naturæ habendum sit, eandem motu quantitatem semper conservari, nisi aliquod impendatur & continuatur; sed hoc tantum lex est corpora servare vim suam ascendentem*, &c. Where it is to be observed, that by hard bodies Huygens means such as are elastic, as appears from his treatise De Motu Corporum & Percussione, Oper. vol. ii.

But it is to be observed, that though it be true, that in the collision of elastic bodies the *vis viva*, or ascensional *force*, is preserved before and after the shock; yet during the shock, while the elastic bodies are bending, and press on each other, there seems to be a diminution of this *force*, which is afterwards restored by the action of their elasticity; though the followers of Leibnitz do not allow that any *force* is lost even during the shock. They say, the *vis viva* is communicated to the spring while it is bending, and then is communicated to the bodies by the unbending of the spring. They also deny that any *force* is lost in the percussion of soft bodies. For though the *force* of the bodies impelling each other be diminished, yet their *force* does not perish, but is communicated to some other matter, such as the subtle fluid causing cohesion and elasticity. *Vis viva quæ in percussione omnium, non parts sed conservatur.* Wolf. Cosmol. § 486. *In tota universi semper conservatur eadem virium vivarum quantitas.* Ibid. § 487. *Vis viva—dum figura corporum in contactu mutatur, in alia materia conservatur.* Ibid. Demonstr. § 486. Mr. Dan. Bernoulli, speaking of this principle of the preservation of the *vis viva*, observes, *Quamvis principium universale sit, non tamen est sine circumfectione adhibendum, quia sæpe contingit ut motus transeat in materiam alteram. Ita verbi gratia pollio illius velocitate pro regulis motuum ex percussione evanescit, si mole corpora sint perfecte elastica; sed imo talia non sunt, facile est videre, partem virium vivarum sive ascensus potentialis in compressionem corporum interioum non restitui sed materiæ eiidem subtilis, ad quam transiit, improvisum bonum.* And Mr. Daniel Bernoulli, in this treatise, has assumed the preservation of the *vis ascendens* of Huygens, or, as others express it, the *conservatio virium vivarum*; and, in Mr. Bernoulli's own expression, *æquilitas inter descensum actualem ascensumque potentialem*, as an hypothesis of wonderful use in mechanics. But a late author contends, that the conclusions drawn from this principle are oftener false than true. See De Conservat. Virium vivarum Dissert. Lond. 1744. 4to.

Mr. Robins, in his remarks on Mr. J. Bernoulli's treatise, entitled, Discours fur les Loix de la Communication du Mouvement, informs us, that Leibnitz adopted this opinion through mistake; for, though he maintained that the quantity of *force* is always the same in the universe, he endeavours to expose the error of Des Cartes, who asserted, that the quantity of motion is always the same; and in his discourse on this subject in the Acta Eruditorum, 1686, he says, that it is agreed on by the Cartesians, and all other philosophers and mathematicians, that there is the same *force* requisite to raise a body of one pound to the height of four yards, as to raise a body of four pounds to the height of one yard; but being shewn how much he was mistaken in taking that for the common opinion, which would, if allowed, prove the *force* of the body to be as the square of the velocity it moved with, he afterwards, rather than own himself capable of such a mistake, endeavoured to defend it as true; since he found it was the necessary consequence of what he had once asserted; and maintained, that the *force* of a body in motion was proportional to the height from which it must fall, to acquire that velocity; and the heights being as the squares of the velocities, the *forces* would be as the masses multiplied by them; whereas, when a body descends by its gravity, or is projected perpendicularly upwards, its motion may be considered as the sum of the uniform and continual impulses of the power of gravity, during its falling in the former case, and till they extinguish it in the latter. Thus, when a body is projected upwards with a double velocity, these uniform impulses must be continued for a double time, in order to destroy the motion of the body; and hence it follows, that the body, by setting out with a double velocity, and ascending for a double time, must arise to a quadruple height, before its motion is exhausted. But this proves that a body with a double velocity moves with a double *force*, since it is produced or destroyed by the same uniform power continued for a double time, and not with a quadruple *force*, though it arises to a quadruple height; so that the error of Leibnitz consisted in his not considering the time, since the velocities alone

alone are not the cauſes of the ſpaces deſcribed, but the times and the velocities together: and yet this is the fallacious argument on which he firſt built his new doctrine; and thoſe which have been ſince much inſiſted on, and derived from the indentings or hollows produced in ſoft bodies, by others falling into them, are much of the ſame kind. Robins's Tracts, vol. ii. p. 178, Maclaurin's View of ſir I. Newton's Diſcov. p. 135.

Catalan and Papin replied to Leibnitz's paper publiſhed in 1686; and from that time the controverſy became more general, and was carried on for ſeveral years by Leibnitz, John and Daniel Bernouilli, Herman, Polcni, Wolfius, s'Graveſande, Camus, Muſchenbroek, &c. on one ſide; and Pemberton, Eames, Deſaguliers, Dr. S. Clark, M. de Mairan, Jurin, Maclaurin, Robins, &c. on the other. See Act. Erud. 1686. 1690. 1691. 1695. & Nouv. de la Rep. Let. Sept. 1686, 1687. art. 2. Comm. Epiſt. inter Leibn. & Bern. Ep. 24. p. 143. Diſcours ſur les Loix de la Comm. du Mouvement, Oper. tom. iii. & Diſſ. de vera Notione Virium vivarum, ib. Act. Petropol. tom. i. p. 131, &c. Hydrodynamica, ſec. 1. Herm. in Act. Fluxions, ubi ſup. & Recueil des Pieces qui ont remporté le Prix, &c. tom i. Deſag. Courſe Exp. Phil. vol. i. p. 393, &c. vol. ii. p. 49, &c. Robins, ubi ſupra.

The nature and limits of this work will not admit our giving a full account of the arguments and experiments which have been repeatedly urged on both ſides of this queſtion. Thoſe who are deſirous of farther information than this article furniſhes, with reſpect to the ſubject in diſpute, may conſult the preceding references. We ſhall, however, endeavour to collect a ſummary account of this controverſy. The chief arguments that have been urged on both ſides, have been deduced from the mutual colliſion of bodies, from the action of ſprings, from the compoſition and reſolution of motion, from the impreſſions made by falling bodies on ſoft ſubſtances, and from ſome experiments in hydraulics relating to the velocities of fluids.

It is a well known law of MOTION, that action and reaction are equal with oppoſite directions, and are to be eſtimated always in the ſame right line; and from this law it follows, that the ſum of the motions of any number of bodies, eſtimated in a given direction, continues the ſame in their mutual actions and colliſions, till ſome external influence diſturbs them. The advocates for the new opinion concerning the *forces* of bodies have found it impoſſible to explain the actions and colliſions of perfectly hard bodies, void of all elaſticity, conſiſtently with their doctrine; and, therefore, they have denied the exiſtence of any ſuch bodies; though it is reaſonable to ſuppoſe, that the ultimate elementary particles of bodies, void of all pores, or atoms, are perfectly hard or inflexible, ſo as not to yield in the ordinary colliſions of bodies; whilſt they have admitted the exiſtence of bodies perfectly elaſtic, none of which are to be met with in nature. Notwithſtanding this evaſion, they have been no leſs puzzled in explaining the colliſion of ſoft bodies, and reconciling the phenomena with their doctrine; for if a ſoft body with the velocity u, ſtrikes another equal ſoft body, they will proceed as in one maſs with the velocity $\frac{1}{2}u$, dividing the motion of the firſt body equally between them by the forementioned law. According to the new opinion, the *force* of the firſt body before the ſtroke was uu, the *force* of each of them after the ſtroke is $\frac{1}{2}u \times \frac{1}{2}u$, or $\frac{1}{4}uu$; and the ſum of their forces after the ſtroke is $\frac{1}{2}uu$; ſo that the ſum of their forces after the ſtroke is only half of what it was before the ſtroke, while the quantity of motion is preſerved the ſame as it was without any change. In order to account for the loſs of one half of the *force* of the firſt body in the ſtroke, they alledge, without proof, that when the parts of ſoft bodies yield without reſtoring themſelves, being void of all elaſticity, a certain quantity of *force* is loſt in the compreſſion of their parts by the colliſion; whereas there is no way by which *force* is loſt in one body, but by the communication of it to another; ſo that there is no juſt reaſon for ſuppoſing, as they have done, that any motion or *force* is loſt in flattening or hollowing ſoft bodies in their colliſions.

If we admit the common rules of finding the velocities of non-elaſtic bodies after colliſion, which Mr. s'Graveſande, an advocate for the new opinion, allows, it will follow, according to that opinion, that equal cauſes may have unequal effects: e. gr. let a and b be two equal non-elaſtic bodies; let b be at reſt, while a moves towards it with eight degrees of velocity. In this caſe, the common velocity, after the ſtroke, will be half the velocity of a before the ſtroke, i. e. four degrees, dividing the ſum of the quantities of motion in the two bodies by the ſum of the quantities of matter: conſequently the force in b, thus communicated by the ſtroke, will be as its ſquare, or 16. Again, let b move forward with two degrees of velocity, and a follow it with ten degrees, the relative velocity will be 8 as before; and, therefore, the ſtrokes in both caſes are equal; the velocity of b after the ſtroke will be half the ſum of the velocities before the ſtroke, or ſix degrees. According to the new opinion, the *forces* being as the ſquares of the velocities, the *force* of b before the ſtroke will be to its force after the ſtroke, as the ſquare of 2 is to the ſquare of 6, i. e. as 4 to 36. Subtract the *force* of b before the ſtroke from the *force* it has after the ſtroke, and you have the degree of *force* communicated by the ſtroke, which, if this opinion be true, would be 32, i. e. double the number of degrees communicated by the ſame *force* in the former inſtance, which was 16; and, therefore, equal ſtrokes produce unequal effects. The impreſſion of the parts, which is the other part of the entire effect of the ſtroke, will make but a ſmall alteration in the matter; ſince the impreſſions in all caſes are equal, when the relative velocity is ſuppoſed to be the ſame.

It has alſo been alledged by the advocates for the new doctrine, particularly by Mr. Bernouilli, that the preſervation of the ſum of the abſolute motions of bodies, in their colliſions, reſults immediately from the equality of action and reaction; the augmentation or diminution of the *force* of the one being the neceſſary conſequence of the diminution or augmentation of the *force* of the other. But the third law of motion is general, and extends to bodies of all kinds; and it is well known that when ſoft bodies meet in oppoſite directions, the ſum of their abſolute motions or *forces* is diminiſhed; and when the bodies are equal, and their velocities likewiſe equal, it is totally deſtroyed by this colliſion; and if two elaſtic bodies meet each other with contrary velocities, then on their firſt compreſſion it is evident, that both their *forces* are diminiſhed at the ſame time, and it may happen, that in reſtoring themſelves, both their *forces* may be increaſed at the ſame time. It is not the ſum of the abſolute motions or *forces* of bodies, but this ſum eſtimated in a given direction, that is preſerved unaltered in their colliſions, in conſequence of the third law of motion; nor can the preſervation of the ſum of the abſolute *forces* of any ſort of bodies be conſidered as the immediate conſequence of it.

The advocates for the new opinion farther maintain, that the *force* of bodies is that power of acting in them, which muſt be meaſured by its whole effect, till its motion be deſtroyed; and they alſo lay it down as a definition or axiom, that *force* is proportioned to the number of ſprings which it can bend before it be conſumed. Accordingly they ſhew, that a body with a velocity as 2, is able to bend and overcome the reſiſtance of four ſprings, one of which alone is equivalent to the *force* of the ſame body moving with a velocity as 1; and hence they infer, that, in the former caſe, the *forces* is quadruple, though the velocity be only double of what it is in the latter caſe. But we may obſerve in general, that cauſes are not to be meaſured by any effects produced by them, conſidered without regard to their circumſtances: thus, motions and *forces* are not to be meaſured by the effects produced, without regard to the times and directions of the motions. It is not conſidered in the preceding argument, and in others of a ſimilar kind, that the *force* which one body loſes, in acting upon another, is not equal to that which it produces or deſtroys in the other, eſtimated in any direction at pleaſure, but in that only in which the firſt body acts; and that body, in conſequence of its *inertia*, not only reſiſts any change in its quantity of motion, but likewiſe any change in the direction of its motion. For the farther illuſtration of this argument, let the bodies A and B (*Tab. III. Mechanics, fig.* 37.) by moving towards each other, compreſs equal and ſimilar ſprings placed between them till by the *re*-action of theſe ſprings their motions be deſtroyed. Mr. Bernouilli expreſly owns, that the actions of the ſprings of theſe bodies are conſtantly equal to each other; and yet maintains that they deſtroy a *force* in B greater than the *force* of A, in the ſame proportion as the body A is greater than B, or (C being the centre of gravity of A and B) as CB is greater than CA. He, therefore, maintains that equal preſſures or actions of ſprings generate, in the ſame time,

forces that may be unequal in any aſſignable ratio, which is repugnant to the plaineſt notions we can form of action and *force*. If we ſuppoſe the body A to compreſs the ſprings from A to C, then the body B will compreſs all the ſprings from B to C, in the ſame degree, and in the ſame time; and thence he infers, that the *force* of A is to the *force* of B in the ſame proportion as the number of ſprings from C to A to the number of ſprings from C to B. But ſince the motion, *forces*, or effect of any kind, produced or deſtroyed in A or B, depends upon the immediate action which produces the effect, and upon it only; and ſince, in this caſe, the actions of the ſprings upon the bodies A and B are thoſe which deſtroy their motion: and ſince it is allowed that the actions of the ſprings on theſe bodies are equal, is it not evident that the *forces* deſtroyed by them in the ſame time muſt be equal? And is it not manifeſt, that the *forces* which are produced or deſtroyed in bodies are to be meaſured by the efforts which the ſprings exert upon the bodies in producing this effect, and not by the number of ſprings? It is the laſt ſpring only which is in contact with the body that acts upon it, the reſt ſerving only to ſuſtain it in its action, and, therefore, any change produced in the body, by whatever name it be called, ought to be determined from the action of this laſt ſpring only, and in juſt reaſoning ought to be computed from this alone. Moreover, if two unequal bodies, moving with unequal velocities, ſtrike upon two equal ſprings, with one end leaning againſt an immoveable ſupport, and each of them bend the ſpring on which it ſtrikes exactly to the ſame degree; and in ſo doing the moving *force* of each body be entirely conſumed; in this caſe there will be, according to the Leibnitzians, two equal effects produced, ſince the ſprings are equal, and equally bent, and the moving *forces* are wholly conſumed in producing them; and, therefore, on their principles, theſe moving *forces*, being the cauſes of equal effects, muſt be equal. But thoſe who eſpouſe the old opinion, deny this concluſion, unleſs the times of producing theſe effects are equal; and they alledge in the preſent caſe that the greater body will take up a longer time in producing its effect, or in bending its ſpring; conſequently the moving *forces* of theſe two bodies may be unequal, though they bend equal ſprings to the ſame degree. In like manner, when a ſpring, already bent to ſome certain degree, does, by unbending, drive before it a body which gave way to its preſſure, the preſſure of the ſpring may produce a greater effect, when it continues for a longer time. Dr. Jurin has very accurately conſidered the action of ſprings. Having premiſed the three following axioms, viz. 1. That a ſpring will unbend itſelf more ſlowly according to the ſize of the body againſt which it acts; 2. That its preſſure is according to the degree in which it is bent; and, 3. That a greater preſſure produces a greater moving *force* in a given time: he deduces from them the following propoſition, viz. the moving *forces* are not proportional to the maſſes of the bodies, and the ſquares of their velocities; for when two ſprings, A and B, equal, and equally bent, puſh before them by unbending two unequal bodies, the ſpring A, which acts on the greater body, will unbend more ſlowly than the other, and, therefore, in every inſtant of time, will have unbent itſelf leſs than B; conſequently its preſſure will be greater than that of B at the ſame inſtant; and the infinitely ſmall moving *force* produced by A in every moment will be greater than that of B; whence it follows, that the ſum of the infinitely ſmall moving *forces*, i. e. the whole moving *force*, produced by A, will be greater than that of B in the ſame time; ſo that the ſpring A, not being wholly unbent, when the preſſure of B ceaſes, will continue to act on the greater body, the moving *force* of which will increaſe, and, therefore, more and more exceed the moving *force* of the ſmaller body; but, ſince the products of the maſſes and ſquares of the velocities are equal in the two bodies, the moving *forces*, which are proved to be unequal, cannot be proportional to the ſame products. He then ſubjoins the two following axioms, viz. 4. That ſprings of unequal lengths, when bent alike, have equal preſſures; and, 5. That equal preſſures in equal times produce equal moving *forces*; from which he deduces his ſecond propoſition, that moving *forces* are proportional to the maſſes and velocities jointly. Thus, if there be two ſprings, of the lengths 1 and 2, but equal in all other reſpects, and bent alike; and the ſpring 1, in unbending itſelf, be made to drive before it a body whoſe maſs is 2, and the ſpring 2 another body of the maſs 1, theſe two ſprings, by what he has elſewhere demonſtrated, will unbend themſelves exactly in the ſame time; and, therefore, the ſpring 2 will unbend itſelf with a velocity double of that of the ſpring 1; and it will give to the body 1 a velocity double of that, which the body 2 will receive from the ſpring 1; conſequently, the two ſprings, during the whole time of their expanſion, will be always bent alike; and, by axiom 4. their preſſures will be conſtantly equal; and by axiom 5. the infinitely ſmall moving *forces* produced by each of theſe ſprings, in every infinitely ſmall part of time, will be equal one to the other; therefore, the ſums of theſe infinitely ſmall moving *forces*, i. e. the whole moving *forces*, produced by the two ſprings, will be equal. And as the maſſes of the two bodies are 2 and 1, and their velocities 1 and 2 reſpectively, the moving *forces* muſt be proportional to the maſſes and velocities jointly. From theſe principles, Dr. Jurin infers, that the Leibnitian opinion about the meaſure of moving *forces* is inconteſtibly overthrown by the firſt propoſition, and the oppoſite opinion evidently eſtabliſhed by the ſecond.

It is a well known theorem in mechanics, that the motions and actions of bodies upon each other, in a ſpace that is carried uniformly forward, are the ſame as if that ſpace were at reſt, and any powers or motions that act upon all the bodies, ſo as to produce equal velocities in them in the ſame or in parallel right lines, have no effect on their mutual actions or relative motions. From this theorem, Mr. Maclaurin has deduced the following argument againſt the new doctrine concerning the *forces* of bodies in motion. Let A and B (*Tab.* III. *Mechanics*, *fig.* 38.) be two equal bodies that are ſeparated from each other by ſprings interpoſed between them in a ſpace E, F, G, H, which in the mean time proceeds uniformly in the direction B A. In which line the ſprings act, with a velocity as 1; and let the ſprings impreſs on the equal bodies A and B equal velocities, in oppoſite directions, that are each as 1. Then the abſolute velocity of A, which was as 1, will be now as 2; and, according to the new doctrine, its *force* as 4; whereas the abſolute velocity, and the *force* of B, which was as 1, will be now deſtroyed; ſo that the action of the ſpring adds to A a *force* as 3, and ſubducts from the equal body B a *force* as 1 only; and yet it ſeems manifeſt that the actions of the ſprings on theſe equal bodies, ought to be equal; which Mr. Bernouilli allows; i. e. equal actions of the ſame ſprings on equal bodies would produce very unequal effects, the one being triple of the other according to the new doctrine, than which hardly any thing more abſurd can be advanced in philoſophy or mechanics. In general, if *m* repreſent the velocity of the ſpace E F G H, in the direction B A, *n* the velocity added to that of A, and ſubducted from that of B, by the action of the ſprings, then the abſolute velocities of A and B will be repreſented by $m+n$ and $m-n$ reſpectively, the *force* added to A by the ſprings will be $2mn+nn$, and the *force* taken from B will be $2mn-nn$, which differ by $2nn$. Farther it is allowed that the actions of bodies upon one another are the ſame in a ſpace proceeding with an uniform motion as if the ſpace was at reſt; but if the ſpace E F G H, was at reſt, it is allowed, that the *forces* communicated by the ſprings to A and B had been equal; and, by the new doctrine, the *force* of each had been repreſented by nn; whereas the *force* communicated to A by the ſprings in the ſpace E F G H, is repreſented by $2mn+nn$, and the *force* taken from B will be $2mn-nn$.

It has been farther urged by the advocates for the new opinion, that, ſince a body moving with a velocity proportional to the diagonal of a rectangle is able to balance the reſiſtance of two ſprings proportional to the ſides of the ſame rectangle, the *force* of a body moving with a velocity, as the diagonal, is equal to the ſum of the *forces* of two bodies moving with velocities proportional to the ſides of the rectangle; and, becauſe the ſquare of the diagonal is equal to the ſum of the ſquares of the two ſides, they thence infer, that the *forces* of equal bodies are as the ſquares of their velocities. Mr. Maclaurin has very largely diſcuſſed this argument, and ſhewn that it contradicts not only their own principles but the eſtabliſhed laws of motion. It is well known to thoſe who are acquainted with the COMPOSITION and RESOLUTION of MOTION, that powers acting in the directions AB and AD (*Tab.* III. *Mechanics*, *fig.* 39.) proportional to thoſe right lines, compound a power acting in the direction of the diagonal AC, and meaſured by it; and this compound power muſt be leſs than the ſum of the ſimple powers, becauſe AC is leſs than AB + AD. This is eaſily accounted for by reſolving the power AB into AM and AN, and the power AD into AK and AL, of which AN and AL are oppoſite and equal, and deſtroy each other's effect, ſo that there remains AM + AK or AC, the meaſure of the compounded power. The followers of Leibnitz agree in this manner of arguing concerning powers and preſſures, but not in the compoſition and reſolution of *forces*; for, according to them, when the angle BAD is right, the compounded *force* is

equal to the sum of the *forces* AB and AD, and no *force* is loſt, notwithſtanding the oppoſite directions of the *forces* AL and AN. When the angle BAD (*fig.* 42.) is acute, the ſquare of the diagonal AC exceeds the ſum of the ſquares of AD and DC, or of AD and AB; and therefore the two *forces* in the directions AD and AB muſt, according to the new doctrine, compound a *force* AC greater than their ſum; a conſequence which contradicts their own metaphyſical principle, that the effect is proportional to the cauſe which produces it, becauſe the effect is, in this caſe, greater than the cauſe, and is an abſurd in mechanics, as that two quantities, collected together ſhould produce a greater quantity than their ſum in geometry; whereas, it appears from a view of the figure, that AL and AN, parts of AD and AB, deſtroy each other; and, therefore, the whole *forces* AD and AB are not accumulated in the direction AC, but only their parts AM and AN, which taken together are equal to AC, becauſe the triangles ADK and DMC are ſimilar and equal; ſo that the *forces* in the directions AB and AD compoſe a *force* in the direction AC leſs than their ſum, whilſt the ſquares of AB and AD, taken together, exceed the ſquare of AC; conſequently the *forces* are not to be meaſured by the ſquares of the lines. Farther, let the elaſtic body A (*fig.* 41.) receive its *forces* in the direction AB, from the equal elaſtic body B, and its *force* in the direction AD, from the equal elaſtic body C, at the ſame time. According to the poſitions of the new doctrine the *forces* of B and C are communicated to A by infinitely ſmall degrees, or by an uninterrupted ſucceſſion of preſſures, and the whole *force* communicated to A is the ſum of the effects of theſe preſſures. Now in every inſtant, the preſſure, or infinitely ſmall *force* impreſſed on A, is leſs than the ſum of the preſſures exerted in that inſtant by B and C, in proportion as AC is leſs than AB + AD, as is allowed on all ſides. Therefore the ſum of all the preſſures, or the *force* impreſſed on A, muſt be leſs than the ſum of all the preſſures, or the ſum of the *forces* exerted by B and C, in the ſame proportion of AC to AB + AD; that is, the *forces* of A, B and C, muſt be as the lines AC, AB, and AD, and not as their ſquares. It is not poſſible to conceive, that, while the *force* in A ariſes from the accumulation of the preſſures, or infinitely ſmall *forces*, which it receives every moment from the actions of B and C, and each of theſe preſſures, or infinitely ſmall *forces*, is leſs than the ſum of the actions of B and C that produce them; yet the whole *force* of A ſhould, nevertheleſs, exceed the ſum of the whole actions or *forces* of B and C. If the angle BAD be infinitely acute, the ſame *forces* (according to the new opinion) generate a *force* in A, which exceeds their ſum as much as the ſquare of AB + AD exceeds the ſum of the ſquares of AB and AD; ſo that if AD be equal to AB, they will in that caſe generate at A a *force* double of their ſum, for then the ſquare of AB + AD will be equal to the ſquare of 2 AB = 4 AB²; though the two equal *forces* which are ſuppoſed to produce this, taken together, amount only to 2 AB, according to their own computation; and, therefore, in this caſe, a cauſe produces an effect of the ſame kind double of itſelf.

In the reſolution of motion, motion is gained; and as the powers that generate motion are increaſed, the effects of theſe powers, or the *forces* of bodies, muſt be increaſed likewiſe. Mr. Maclaurin has illuſtrated and applied this principle in the following manner. Let the body C (*fig.* 42.) moving in the direction DC, the diagonal of the parallelogram, C I. D K, ſtrike the equal body A obliquely, ſo as to impel it in the direction C A, the continuation of CK, and at the ſame time the equal body B, in the direction CB, the continuation of CL; the body A will proceed in the right line CA, and the body B will proceed in the direction CB, the continuation of CL, and C having communicated all its *force* to them, will ſtop. It will not appear ſtrange, that the motions and *forces* of A and B exceed the motion or *force* of C, if we conſider that C communicates the whole motion or *force* CK to A, and the whole motion or *force* CL to B, that the reſiſtance or *inertia* of A reacting upon C, not in the direction of its motion CD, but in the direction CK, oblique to it, the abſolute motion or *force* of C, in the direction of DC, is not ſo much diminiſhed by this reaction as if it was directly oppoſite to the motion of C; for no power or reſiſtance can produce ſo great an effect in any direction as in that wherein it acts. In like manner, the reaction of B deſtroys the *force* LC in the body C, in the direction in which B reacts; but not ſo great a motion or *force* in the direction DC, to which it is oblique; and thus it appears, that the motion or *force* of C, in the direction DC, muſt neceſſarily be leſs than the ſum of the motions or *forces* of the bodies A and B in their reſpective directions. It may alſo be obſerved, that in conſequence of the *inertia* of body, it not only reſiſts any change of its motion, but likewiſe any change in the direction of its motion; and when the action of bodies upon each other is not in a right line, both theſe are to be taken into the account. Thus, if C ſtrike A, the reaction of A has a twofold effect; it ſubducts ſomewhat from the motion or *force* of C, and produces a change in its direction; and its whole reaction is to be eſtimated by both theſe effects conjointly. After the body C has ſtruck A, it proceeds in the right line CB with a motion or *force* as CL, and, impinging on B directly, it communicates its whole motion or *force* to B, which reacts directly againſt it; the bodies C, A, and B, are ſuppoſed to be perfectly elaſtic. If ſprings be ſubſtituted, inſtead of the bodies A and B, and their reſiſtances meaſured by CK and CL, the reſiſtances of theſe ſprings are not the proper meaſures of the *force* of the body C, but taken together, they muſt exceed it; becauſe the ſpring A acts at a diſadvantage againſt the motion or *force* of C. It has its whole effect in the direction CK, in which it reſiſts; but not ſo great an effect in the direction CD, oblique to that in which it acts. If the ſpring A acted with the ſame advantage as B, they would together produce a greater effect than in the ſituation they have in the figure; and, therefore, the greateſt reſiſtances which they are able to exert taken together, muſt exceed the *force* of the body C. Thus, ſays Mr. Maclaurin, it appears, that this argument, inſtead of overthrowing the old doctrine, confirms it, and that they who advanced it ſuppoſed thoſe *forces* to be equal, which, according to the known principles of mechanics, are unequal. In other inſtances, the followers of M. Leibnitz neglect the conſideration of time, in reaſoning concerning the *forces* of bodies; in this caſe they do not duly regard the directions of motions and *forces*, in eſtimating and comparing their effects. Mr. Eames has likewiſe ſhewn, that the argument drawn from the compoſition and reſolution of *forces*, equally proves both ſides of the queſtion, and by this proving too much, proves nothing. Another argument advanced in favour of the new opinion, has been founded on the learned and ingenious Mr. Poleni's experiment, in which equal cavities are formed in ſoft ſubſtances, by equal bodies falling from heights reciprocally proportional to their maſſes; whence it has been inferred, that the bodies ſtrike with equal *force*, and, therefore, that the *force* of the ſame body in deſcending is proportional, according to Mr. Leibnitz's principle, to the height from which it falls, or, in all motion, proportional to the ſquare of the velocity. Dr. Jurin has ſet this argument aſide, as inſufficient, ſince the times of forming theſe equal cavities are unequal and unequal cauſes may produce equal effects in unequal times. Mr. Poleni, indeed, maintains, that the formation of theſe cavities ſeems to be inſtantaneous; but Dr. Jurin has ſhewn the contrary, even from a poſition allowed by Poleni himſelf. Dr. Pemberton aſſerts and proves, that this experiment of Poleni is not only reconcileable to the common doctrine of motion, but that it manifeſtly the great unreaſonableneſs, if not the abſolute abſurdity, of Mr. Leibnitz's opinion: and Dr. Desaguliers obſerves, that Poleni's ſubſtance line in which that he eſtimates the *force* of the ſtroke of the falling balls, by the depth of the impreſſion made in the yielding ſubſtances; but this is not the whole effect; for when two bodies move with equal *forces*, but different velocities, that which moves the ſwifteſt muſt make the deepeſt impreſſion, whilſt the ſlower body communicates its motion to the ſubſtances round about, and, therefore, does not ſtrike in ſo deep as the ſwifter body, which puts in motion few parts of the clay, beſides thoſe that are before it, and which have ſo much leſs time to oppoſe this body's motion, as its velocity is greater.

The ingenious Mr. Graham, in confirmation of the old opinion, prepared a pendulous body, with a cavity in it, capable of receiving another body of an equal weight, at the loweſt point of its vibration; and when the body was dropped into it, he found, by the ſubſequent vibration, that the velocity of the double maſs was preciſely one half of the velocity of the pendulum before; from which it appears, that the ſame *force* produces in a double quantity of matter one half of the velocity only; which is agreeable to the common doctrine, but directly repugnant to the new one, concerning the *forces* of bodies in motion.

The advocates for the new opinion have produced in favour of it ſome experiments in hydraulics, the reſult of which is, that the velocities of any fluid, iſſuing out at equal orifices made in the ſides of veſſels filled up to different heights, and kept full at thoſe heights, above the orifices, are found to be as the ſquare roots of thoſe heights reſpectively; whence they infer, that the *forces* of equal maſſes, or moving bodies, are proportional to

the squares of their velocities. Every single particle, they say, iſſuing out with two degrees of velocity, muſt move with four times the *force* of any other ſingle particle that moves with only one degree of velocity; becauſe the *force* with which it moves is the effect of a cauſe four times greater, or the preſſure of a column of water four times higher, &c. The preſſures are as the altitudes, and the altitudes as the ſquares of the velocities of every ſingle particle; therefore the preſſures are as the ſquares of the velocities; but the preſſures being the cauſes of the *forces*, with which the ſeveral particles iſſue out or move, and effects being proportional to their cauſes, the *forces* muſt be as the ſquares of the velocities. On this reaſoning, Mr. Eames has remarked, that the entire effect of any of theſe preſſures is not barely a certain number of degrees of velocity, in any ſingle particle, but certain degrees of velocity in a certain number of particles, which number of particles, in a given time, is, confeſſedly, as the degrees of velocity. Beſides, it is acknowledged, that the quantities of the fluid, preſſed out in equal times, are as the velocities. See s'Graveſ. Epit. Elem. Phyſ. Math. part ii. cap 4. p. 665.

If this be true, the *forces* cannot be as the quantities of matter multiplied by the ſquares of the velocities; *for* then the effects would be more than in proportion to their cauſes. E. gr. the effect of a preſſure of a column of water, nine inches high, inſtead of being nine times greater than that of one inch above the *orifice*, would be no leſs then twenty-ſeven times greater; for the velocity being at this height triple, the quantity of matter, in a given time, will be alſo triple; which multiplied by the ſquare of the velocity gives 27 for the *force* communicated by a preſſure of 9 inches in altitude, while the *force* communicated by the preſſure of 1 inch, is but as 1; ſo that the moving *forces* produced will be as 27 to 1, while the cauſes producing theſe *forces* are but as 9 to 1, i. e. three times too little for ſuch a purpoſe. In reality the common rule of eſtimating the *forces* of moving bodies by the quantities of matter multiplied by their velocities, is confirmed by theſe experiments; *for*, effects being proportional to their cauſes, the *forces* communicated will be as the *forces* communicating, or preſſures. Thus, let the altitude and conſequent preſſure of any column of water, be nine times greater than the altitude of another; then the velocity of every ſingle particle of water preſſed out will be triple, and the number of particles iſſuing out in a given time will likewiſe be triple; therefore, the *force* reſulting from theſe 2, multiplied together, according to the common rule, will be 9, proportional to the preſſure, as it ought to be, &c. And univerſally, the *forces* communicated, according to the old rule, are in a ratio compounded of two others, viz. the quantities of matter and the velocities; the ratio of the velocities, by the experiments, is the ſubduplicate ratio of the heights, and the ratio of the quantities of matter is, confeſſedly, likewiſe the ſubduplicate of the heights; therefore the compound of theſe two is the ratio integra, or ſimple ratio of the heights; in which ratio are the preſſures themſelves, which produce theſe moving *forces*; ſo that, according to the common rule, the effects are always proportional to their cauſes. After this manner profeſſor s'Graveſande reaſons in para. 355. of his Phyſ. El. Math. ed. 1.

Many of the experiments and reaſonings, that have been urged on both ſides in this controverſy, have been founded in the different ſenſes applied to the term *force*. The Engliſh and French philoſophers mean by the word *force* the ſame thing as they do by momentum, motion, quantity of motion, or inſtantaneous preſſure, which is meaſured by the maſs multiplied into the velocity, and may be known by its effect; and when they conſider bodies as moving through a certain ſpace, they allow for the time in which that ſpace is deſcribed; whereas the Dutch, Italians and German philoſophers, who have eſpouſed the new opinion, mean by the word *force*, or *force* inherent in a body in motion, that which it is able to produce; or, in other words, the *force* is always meaſured by the whole effect produced by the body in motion, until its whole *force* be entirely communicated or deſtroyed, without any regard to the time employed in producing this total effect. Thus, ſay they, if a point runs through a determinate ſpace, and preſſes with a certain given *force* or intenſity of preſſure, it will perform the ſame action whether it move faſt or ſlow, and therefore the time of the action in this caſe ought not to be regarded. s'Graveſande, lib. cit. § 723—726.

Leibnitz himſelf aſſumed it as certain, that the action is as the effect by the velocity with which it is produced; and hence he deduces, that the power is as the maſs by the ſquare of the velocity: his words, as quoted by Wolfius, are, *Calculum virium parandum ſeu actionum talem inſtituo. Sit ſpatium s, tempus t, velocitas v, corpus c, effectus e, potentia p, actio a, in motu aequabili erit* $v = \frac{s}{t}$, $e = c \times \frac{s}{t}$, $p = c \times \frac{s}{t} \times \frac{s}{t}$, $a = c \times \frac{s}{t} \times \frac{s}{t} \times t$. *Atque haec quidem ſine demonſtratione aſſumi poſſunt. Accedit quod demonſtrandum. ex ut a. Huic parva plurimo determinato demonſtrari poſſunt, e. gr. p ut ee. Nam ſi ut ee: ſed e ut c × ss : tt ut ee. Ergo ſi p ut c × ss, ſeu p ut ee.* Vide Act. Petrop. tom. i. p. 252.

Mr. Euler obſerves, with reſpect to this diſpute concerning the meaſure of vivid *force*, that we cannot abſolutely aſcribe any *force* to a body in motion, whether we ſuppoſe this *force* proportional to the velocity, or to the ſquare of the velocity; for the *force* exerted by a body, ſtriking another at reſt, is different from that which it exerts in ſtriking the ſame body in motion; ſo that this *force* cannot be aſcribed to any body conſidered in itſelf, but only relatively to the other bodies it meets with. There is no *force* in a body, abſolutely conſidered, but its inertia, which is always the ſame, whether the body be at reſt or in motion. But if this body be forced by others to change its ſtate, its inertia then exerts itſelf as a *force*, properly ſo called, which is not abſolutely determinable; becauſe it depends on the changes that happen in the ſtate of the body. Suppoſe, for inſtance, a body A forced to move in an incurvated tube, or along the curve ſurface E a F (*Tob. Mathonicis, fig.* 43.) the body in this caſe will preſs the ſurface wherever it touches it in a direction a a normal to the curve; and with a certain *force* commonly determined in mechaniſm, by the maſs of the body, its velocity, and by the radius of curvature O a. Now the body exerts a preſſure, or *vis mortua*; yet it would be abſurd to aſcribe a certain and determinate *force* of preſſure to this body conſidered in itſelf, ſince this preſſure may vary very much, according to the difference of the curvature of E a F. In like manner it ſeems unreaſonable to place a certain abſolute *force* of percuſſion in bodies, ſince it principally depends on the external circumſtances accompanying the ſhock.

A ſecond obſervation which has been made by ſeveral great men, is, that the effect of a ſhock of two or more bodies is not produced in an inſtant, but requires a certain interval of time. If this be ſo, the heterogeneity between the *vires vivæ* and *mortuæ* vaniſhes; ſince a preſſure may always be aſſigned, which in the ſame time, however little, ſhall produce the ſame effect. If then the *vires vivæ* be homogeneous to the *vires mortuæ*, and ſince we have a perfect meaſure and knowledge of the latter, we need require no other meaſure of the former than that which is derived from the *vires mortuæ* equivalent to them.

Now that the change of the ſtate in the ſhock of two bodies does not happen in an inſtant, appears evidently from the experiments made on ſoft bodies; for, percuſſion forms a ſmall cavity, viſible after the ſhock, if the bodies have no elaſticity. Such a cavity cannot certainly be made in an inſtant. And if the ſhock of ſoft bodies require a determinate time, we muſt certainly ſay as much of the hardeſt, though this time may be ſo ſmall as to be beyond all our ideas. Neither can any inſtantaneous ſhock agree with that conſtant law of nature, by virtue of which nothing is performed *per ſaltum*. But it is needleſs to inſiſt farther on this, ſince the duration of any ſhock may be determined from the moſt certain principles.

There can be no ſhock or colliſion of bodies, without their making mutual impreſſions on each other: theſe impreſſions will be greater or leſs, according as the bodies are more or leſs ſoft, other circumſtances being the ſame. In bodies called hard, the impreſſions are ſmall; but a perfect hardneſs, which admits of no impreſſion, ſeems inconſiſtent with the laws of nature; ſo that while the colliſion laſts, the action of bodies is the reſult of their mutually preſſing each other. This preſſure changes their ſtate: and the *forces* exerted in percuſſion are really preſſures, and truly *vires mortuæ*, if we will uſe this expreſſion, which is no longer proper, ſince the pretended infinite difference between the *vires vivæ* and *mortuæ* ceaſes. See HARD *bodies*.

The *force* of percuſſion, reſulting from the preſſures bodies exert on each other while the colliſion laſts, may be perfectly known, if theſe preſſures be determined for every inſtant of the ſhock.

The mutual action of the bodies begins the firſt moment of their contact, and is then leaſt; after which this action increaſes, and becomes greateſt when the reciprocal impreſſions are ſtrongeſt. If the bodies have no elaſticity, and the impreſſions they have received remain, the *forces* will then ceaſe. But if the bodies be elaſtic, and the parts compreſſed reſtore themſelves to their former ſtate, then will the bodies continue to preſs each other till they ſeparate. To comprehend therefore perfectly the *force* of percuſſion, it is requiſite to define firſt, the time the ſhock laſts, and then to aſſign the preſſure correſpond-

responding to each inſtant of this time; and as the effect of preſſures in changing the ſtate of any body may be known, we may thence come at the true cauſe of the change of motion ariſing from collision. The *force* of percuſſion, therefore, is no more than the operation of a variable preſſure during a given time; and to meaſure this *force* we muſt have regard to the time, and to the variations according to which the preſſure increaſes and decreaſes.

Mr. Euler has given us ſome calculations with reſpect to theſe particulars. It will be ſufficient here only to illuſtrate their tendency by the inſtance he brings. Suppoſe two bodies A and B; that the hardneſs of theſe bodies is equal; and ſuch, that being preſſed together with the *force* of 100 lb. the impreſſion made on each is of the depth of $\frac{1}{1000}$ part of a foot. Suppoſe, farther, B to be at reſt, and faſed, and that A ſtrikes it with the velocity of a 100 feet in a ſecond; according to Mr. Euler, the greateſt *force* of compreſſion will be equivalent to 4000 lb. and this *force* will produce in each of theſe bodies an impreſſion equal to $\frac{1}{4}$ of a foot; and the duration of the colliſion, that is, till the bodies arrive at their greateſt compreſſion, will be about $\frac{1}{1000}$ of a ſecond. Mr. Euler, in his calculations, ſuppoſes the hardneſs of a body to be proportional to the *force* or preſſure requiſite to make a given impreſſion on it; ſo that the *force* by which a given impreſſion is made on a body, is in a compound ratio of the hardneſs of the body and of the quantity of the impreſſion. But he obſerves, that regard muſt be had to the magnitude of the bodies, as the ſame impreſſion cannot be made on the leaſt bodies as on the greateſt, from the defect of ſpace through which their component particles muſt be driven: he, therefore, only conſiders the leaſt impreſſions, and that the bodies are of ſuch magnitudes, that with reſpect to them the impreſſions may be looked upon as nothing. What he ſuppoſes about the hardneſs of bodies, neither implies elaſticity nor its effect, elaſticity only producing a reſtitution of figure and impreſſion when the preſſing *force* ceaſes; but this reſtitution needs not be here conſidered. It is likewiſe ſuppoſed that the bodies ſtriking each other have plane and equal baſes, by which they touch each other in the colliſion; ſo that the impreſſion hereby made diminiſhes the length of each body. It is farther to be obſerved, that in Mr. Euler's calculations, bodies are ſuppoſed to continue that they may not only receive impreſſions from the *forces* preſſing them, but that a greater *force* is requiſite to make a greater impreſſion. This excludes all bodies fluid or ſolid, in which the ſame *force* may penetrate farther and farther, providing it have time, without ever being *in equilibrio* with the reſiſtance. Thus a body may continually penetrate farther into ſoft wax, although the *force* impelling it be not increaſed. In theſe, and the like caſes, nothing is required but to ſurmount the firſt obſtacles; which being once done, and the connection of parts broken, the penetrating body always advances, meeting with the ſame obſtacles as before, and deſtroying them by an equal *force*. But Mr. Euler only conſiders the firſt obſtacles which exiſt before any ſeparation of parts, and which are, no doubt, ſuch, that a greater impreſſion requires a greater *force*. This, indeed, principally takes place in elaſtic bodies; but it ſeems likewiſe to obtain in all bodies when the impreſſions made on them are ſmall, and the contexture of their parts is not altered.

Theſe things being premiſed, let the maſs or weight of the body A be expreſſed in general by A, and let its velocity before the ſhock be that which it might acquire by falling from the height *a*. Further, let the hardneſs of A be expreſſed by M, and that of B by N, and let the amplitude of the baſe by which the impreſſion is made, be *cc*; then will the greateſt compreſſion be made with a *force* $\sqrt{\frac{MNcc}{M+N}} \times Aa$. Therefore if the hardneſs of the two bodies, and the plane of their contact during the whole time of their colliſion be the ſame, this *force* will be $\sqrt{A}\,a$, that is, as the ſquare root of the *vis viva* of the ſtriking body A. And as $\sqrt{a}$ is proportional to the velocity of the body A, the *force* of percuſſion will be in a compound ratio of the velocity and of the ſubduplicate ratio of the maſs of the body ſtriking; ſo that in this caſe neither the Leibnitian nor the Carteſian proportions take place. But this *force* of percuſſion depends chiefly on the hardneſs of the bodies; the greater this is, the greater will the *force* of percuſſion be. If M = N, this *force* will be as $\sqrt{Mcc} \times Aa$, that is, in a compound ſubduplicate ratio of the *vis viva* of the body ſtriking, of the hardneſs, and of the plane of contact. But if M, the hardneſs of one of the bodies, be infinite, the *force* of percuſſion will be as $\sqrt{Ncc} \times Aa$; at the ſame time, if M = N, this *force* will be as $\sqrt{\frac{1}{2}Ncc} \times Aa$. Therefore all other things being equal, the *force* of percuſſion if the ſtriking body be infinitely hard, will be to the *force* of percuſſion, if both the bodies be equally hard, as $\sqrt{2}$ to 1. Mr. Euler farther deduces from his calculations, that the impreſſion received by the body A will be as $\sqrt{\frac{N \times a}{M - N \times M}}$, and the impreſſion on B will be as $\sqrt{\frac{M \times a}{M + N \times N}}$. If, therefore, the hardneſs of A, that is M, be infinite, it will ſuffer no impreſſion, whereas that on B will extend to the depth of $\sqrt{\frac{Aa}{Ncc}}$. But if the hardneſs of the two bodies be the ſame, or M = N, they will each receive equal impreſſions to the depth $\sqrt{\frac{Aa}{2Ncc}}$. So that the impreſſion received by the body B, in this caſe, will be to the impreſſion it receives in the former as 1 to $\sqrt{2}$.

Mr. Euler has likewiſe conſidered and computed the caſe when the ſtriking body has its anterior ſurface convex, with which it ſtrikes an immoveable body whoſe ſurface is plane. He has alſo examined the caſe when both bodies are ſuppoſed immoveable; and from his formulæ he deduces the known laws of the colliſion of inelaſtic and elaſtic bodies. He has alſo determined the greateſt preſſures the bodies receive in theſe caſes; and likewiſe the impreſſions made on them. In particular he ſhews, that the impreſſion received by the body ſtruck, or B, if moveable, is to the impreſſion received by the ſame body when immoveable as $\sqrt{B}$ to $\sqrt{A+B}$.

This ſhort account of Mr. Euler may ſerve to ſhew, that the diſputes about the meaſure of *forces* is very needleſs in phyſics; ſince the laws of motion may, independently of any hypotheſis about the meaſure of the *vis viva*, be deduced from the moſt unconteſted principles of preſſure and time. But we doubt whether we ſhall be enabled hereby to ſettle the metaphyſical part of this diſpute to the ſatisfaction of both parties, each of which may aſſent to all that Mr. Euler ſays, and yet adhere either to the Carteſians or Leibnitians. But whatever may be ſaid of the metaphyſical part of the diſpute, it is certain, from experience,

That the number of equal ſprings requiſite to produce any velocity in a given body, is always proportional to the ſquare of the velocity to be produced. Thus if one ſpring can, by unbending half, produce one degree of velocity in a body, it will require four equal ſprings to produce two degrees of velocity in that body; nine ſprings to produce three degrees of velocity, &c. See SPRING.

Alſo, if a portion of a yielding ſubſtance, as clay, tallow, &c. be juſt ſufficient to ſtop the motion of a body moving with a certain degree of velocity, it will require four times the quantity of the ſame yielding ſubſtance to ſtop it, if the velocity of the moving body be double, &c. The ſame holds in the reſiſtance of wood againſt muſquet-balls, as Mr. Robins obſerves in his New Principles of Gunnery; ſo that a ball moving with twice the velocity of another, will penetrate four times as deep into earth, clay, tallow, wood, &c. And in like manner if the action of one man, one horſe, or other animal, can give a certain degree of velocity to a given maſs, it will require the action of four equal men, horſes, &c. to give the ſame maſs two degrees of velocity; nine men, horſes, &c. to give it three degrees of velocity; and ſo on.

Theſe practical points have been put out of all queſtion by the experiments of Poleni, s'Graveſande, Deſaguliers, and others, and are of great uſe, although they do not decide the controverſy about the meaſure of the *force* of bodies in motion.

FORCE, *accelerating*. See VIS *acceleratrix*, and ACCELERATION.

FORCE, *attractive*. See ATTRACTION.

FORCE, *central*. See CENTRAL.

FORCE, *centrifugal*. See CENTRIFUGAL.

FORCE, *centripetal*. See CENTRIPETAL.

FORCE *of inertion*. See CORRETION.

FORCE, *contractile*. See CONTRACTILE.

FORCE, *elaſtic*. See ELASTIC, and ELASTICITY.

FORCE, *electrical*. See ELECTRICITY.

FORCE *of gravity*. See GRAVITY.

FORCE, *retarding*. See RETARDATION.

FORCE *of wind*. See WIND, &c.

FORCE, in *Common Law*, ſignifies an offence, by which violence is uſed either to perſons, or things.

Force is either *ſimple*, or *compound*.

FORCE, *mixed*, or *compound*, is violence committed with ſome facts, which of itſelf alone were criminal: as if any man by *force* enter into another man's poſſeſſion, and there kill a man, or raviſh a woman, &c.

FORCE, *ſimple*, is that which has no other crime adjoined to it: if one, by *force*, enter into another man's poſſeſſion, without doing any other unlawful act.

FORCE is alſo divided into *true force*, or *force after a fort*.

There are other branches of FORCIBLE entries, *forcible* detaining, or holding unlawful aſſembly, routs, riots, rebellions, &c.

FORCE, *ſnuff*. See FRESH.

FORCE, in *Grammar*, and ſome other arts, is applied to a thing which ſtands in lieu of, or has the ſame effect, as another. In our language, the *f* between two vowels has the *force* or power of a *v*, and is ſometimes put for a *v*; as in horſon, bapiſing, &c.

In Hebrew, the daleth; and in Arabic, the teſtith; have the *force* of a letter ſuppreſſed. An unit before a cypher, has the *force* of ten.

FORCE, in *practical Mechanics*. We have ſeveral curious as well as uſeful obſervations in Deſaguliers's Experimental Philoſophy, concerning the comparative *forces* of men and horſes and the beſt way of applying them. A horſe draws with the greateſt advantage when the line of direction is level with his breaſt; in ſuch a ſituation, he is able to draw 200 lb. eight hours a day, walking about two miles and an half an hour. And if the ſame horſe is made to draw 240 lb. he can work but ſix hours a day, and cannot go quite ſo faſt. On a carriage, indeed, where friction alone is to be overcome, a middling horſe will draw 1000 lb. But the beſt way to try a horſe's *force*, is by making him draw up out of a well, over a ſingle pully or roller; and in ſuch a caſe, one horſe with another will draw 200 lb. as already obſerved.

Five men are found to be equal in ſtrength to one horſe, and can, with as much eaſe, puſh round the horizontal beam of a mill, in a walk forty feet wide; whereas three men will do it in a walk only nineteen feet wide.

The worſt way of applying the *force* of a horſe, is to make him carry or draw up hill: for, if the hill be ſteep, three men will do more than a horſe, each man climbing up ſwifter with a burden of 100 lb. weight, than a horſe that is loaded with 300 lb. a difference which is owing to the poſition of the parts of the human body being better adapted to climb than thoſe of a horſe.

On the other hand, the beſt way of applying the *force* of a horſe, is an horizontal direction, wherein a man can exert ſcarſe *force*; thus a man, weighing 140 lb. and drawing a boat along, by means of a rope coming over his ſhoulders, cannot draw above 25 lb. or exert above one ſeventh part of the *force* of a horſe employed to the ſame purpoſe.

The very beſt and moſt effectual poſture in a man, is that of rowing; wherein he not only acts with more muſcles at once for overcoming the reſiſtance, than in any other poſition; but as he pulls backwards, the weight of his body aſſiſts by way of lever. Deſaguliers, exp. Phil. vol. i. p. 241. where we have ſeveral other obſervations relative to *force* acquired by certain poſitions of the body, from which that author accounts for moſt feats of ſtrength and activity. See alſo a Memoire on this ſubject by M. de la Hire, in Mem. Roy. Acad. Sc. 1699; or in Deſaguliers, Exp. &c. p. 267, &c. who has publiſhed a tranſlation of part of it with remarks.

FORCEPS, a ſurgeon's inſtrument, wherewith dead and corrupt parts are ſeized, cut, or pulled off, &c. As alſo foreign bodies extracted out of wounds, &c.

The word literally denotes a pair of tongs.

They are of divers forms; long, crooked, with teeth, with beaks, half-mooned, &c. See *Tab. Surgery, fig.* 14, *Tab.* III. *fig.* 31. 34. 43.

Mr. Monro deſcribes and gives a figure of a *forceps*, the mouth of which has on each ſide two ſmall ſharp teeth, which apply cloſe to one another when it is ſhut. This *forceps*, when ſhut, may be ſafely introduced into a gun-ſhot wound, and the bodies being immediately opened behind the bullet, the teeth will pierce into the lead, and hold it faſt enough to bring it out, though they are not advanced ſo far as the largeſt part of it. Med. Eſſ. Edinb. vol. v. art. 41.

Dr. Le Cat has contrived a new *forceps* for the extirpation of tumors, the extraction of ſtones, &c. for an account of which, ſee Phil. Tranſ. N° 491. or vol. xlvi. p. 80, &c.

The *forceps* is alſo uſed for extracting the fœtus in caſes of preternatural delivery. The inſtrument uſed for this purpoſe is either ſtrait or curved. The ſtrait *forceps* is uſed for bringing the head of the child forward, when on account of its ſize, or the want of paint, it cannot otherwiſe be protruded; but the uſe of them requires great care: and it is obſerved, that inſtruments of this kind are never neceſſary, whilſt the head is above the brim of the pelvis, and rarely when it hath deſcended lower. Dr. Hunter abſolutely forbids the uſe of them, if they can poſſibly be avoided. Thoſe improved by Smellie are the beſt, who has reduced their length, in order to prevent their being uſed before the head is low enough. The long curved *forceps* was invented by Smellie, with a view to ſaving the life of the child, when the body being delivered, the head could not be brought away in the uſual manner. Theſe are longer than the ſtrait ones, becauſe they are applied, when the head of the child is above the brim of the pelvis. The ſtrait and curved *forceps*, as well as the blunt hook, are uſed to expedite and facilitate delivery; whereas the crotcher, which has a hook at its point that is forced into the part to which it is applied, wounds, and generally kills the child.

FORCER, in *Mechanics*, is properly a PISTON, without a valve.

There are ſeveral ways of making *forcers*: the moſt common of all conſiſts of a braſs cylinder, a very little leſs in diameter, at its bottom and top, than the bore of the barrel of the pump, and turned ſtill leſs at the middle, in order to let in a leathern ring or collar (made of a thick leather put round the braſs cylinder), which makes it juſt equal to the bore of the barrel, ſo as to fit it quite when it is put into it.

The ſecond ſort of *forcers* conſiſts of three braſs cylinders, which can be ſcrewed together. The middle one ought to be almoſt equal in diameter to the bore of the pipe, ſo as to ſlide in it without any friction. The upper cylinder and the lower muſt be a little leſs, and equal to one another. There are two leathers which muſt be put between them when they are unſcrewed: then it is evident, that if the cylinders be ſcrewed together, and the leathers, which ought to be a little bigger than the braſs cylinders, apply themſelves folding upwards round the upper cylinder, and downwards round the lower, they will become juſt equal to the bore of the barrel, and conſequently they will hinder any air from getting through the ſides of the *forcer*, when it moves up and down in the barrel. The uſe of the middle braſs cylinder is to hinder the leathers from turning themſelves back by the motion.

This kind of *forcer* has above the other, the advantage of having a great deal leſs friction; and beſides, as the leathers, which are applied to it, may be thin ones, they are much ſmoother than thick ones, which are uſed in the other.

But the beſt way of making *forcers*, is to have a plunger, or ſolid braſs cylinder, equal in length to the barrel of the pump, and a little leſs in the diameter than the bore; ſo that it may move freely in it without any friction. There muſt be two hollow, ſhort, braſs cylinders, or rather rings, at the top of the barrel, which can be ſcrewed together; the upper one muſt be equal in bore to the barrel, and the lower a little leſs: there are two leathers, both having in the middle a leſs hole than in the bore of the pipe; the one muſt be applied between the barrel and the lower ring, and the other between the ſame ring and the upper one; and the whole muſt be ſcrewed together. Then if the ſolid cylinder or *forcer* be put into it, and moved up and down, it is evident that the two before mentioned leathers, which are applied the one to the barrel and the other to the inſide of the hollow cylinder, will hinder any air from getting between them and the ſolid cylinder.

The advantage of this kind of *forcer* is, that it has no other friction but at the top of the barrel, and that the inſide of the barrel need not be ſmooth, as in other kinds of pumps; but only the outſide of the *forcer* muſt be turned true and poliſhed, which can be done with much more eaſe, and the lower part muſt be turned a little conical, that it may be brought into the barrel, without any reſiſtance of the upper leather of the collar of jack-head. See Deſaguliers, Courſe of Experim. Philoſ. vol. ii. p. 161, 162.

FORCIBLE *Entry*, a violent, actual entry into houſes, or lands, &c. with menaces or weapons, whether violence or hurt be offered to any perſon therein, or not.

FORCIBLE *holding*, or *detaining*, a with-holding by violence, and with a ſtrong hand, of the poſſeſſion of land, &c. whereby he who has a lawful right of entry is barred or hindered. See ENTRY.

This was formerly allowable to every perſon diſſeiſed, or turned out of poſſeſſion, unleſs his entry was taken away or barred by his own neglect, or other circumſtances. But this being found very prejudicial to the public peace, it was thought neceſſary, by ſeveral ſtatutes, to reſtrain all

all persons from the use of such violent methods even of doing themselves justice: so that the entry now allowed by law is a peaceable one. By the several statutes of 15 Ric. II. cap. 2. 8 Hen. VI. cap. 9. 31 Eliz. cap. 11. and 21 Jac. I. cap. 15. upon any *forcible* entry, or *forcible* detainer after peaceable entry into any lands or benefices of the church, one or more justices of the peace, taking sufficient power of the county, may go to the place, and there record the force upon his own view, as in case of riots; and upon such conviction, may commit the offender to gaol, till he makes fine and ransom to the king. And the justice or justices have power to summon a jury, to try the *forcible* entry or detainer complained of; and if the same be found by that jury, then, besides the fine on the offender, the justices shall make restitution by the sheriff of the possession, without inquiring into the merits of the title; for the force is the only thing to be tried, punished, and remedied by them; and the same may be done by indictment at the general sessions. But this provision does not extend to such as endeavour to maintain possession by force, where they or their ancestors have been in the peaceable enjoyment of the lands and tenements for three years immediately preceding.

FORCIBLE *abduction* and *marriage*, vulgarly called stealing an heiress. By stat. 3 Hen. VII. cap. 2. it is enacted, that if any person shall, for lucre, take any woman, maid, widow, or wife, having substance either in goods or lands, or being her apparent heir, against her ancestors, contrary to her will, and afterwards she be married to such misdoer, or by his consent to others, or defiled; such person, and all his accessaries, shall be deemed principal felons; and by stat. 39 Eliz. cap. 9. the benefit of clergy is taken away from all such felons, except accessaries after the offence. See MARRIAGE.

FORCING, in the *winemerchant*, a term used by the wine-cooper for the FINING down wines, and rendering them fit for immediate draught.

The principal inconvenience of the common way of FINING down the white-wines by isinglass, and the red by whites of eggs, is the flowness of the operation; these ingredients not performing their office in less than a week, or sometimes a fortnight, according as the weather proves favourable, cloudy or clear, windy or calm: this appears to be matter of constant observation. But the wine-merchant frequently requires a method that shall, with certainty, make the wines fit for tailing in a few hours. A method of this kind there is, but it is kept in a few hands a valuable secret. Perhaps it depends upon a prudent use of a tartarized spirit of wine, and the common *forcing*, as occasion is, along with gypsum, as the principal; all which are to be well stirred about in wine, for half an hour before it is suffered to rest. Shaw's Lectures, p. 208.

FORCING, among *Gardeners*, is used for producing ripe fruits from trees before their natural season. The method of doing it is this: a wall should be erected ten feet high; a border must be marked out on the south side of it, of about four feet wide: and some blanket must be fastened into the ground all along the edge of the border; these should be four inches thick. They are intended to rest the glass-lights upon, which are to slope backwards to the wall, to shelter the fruit as there shall be occasion; and there must be at each end a door to open either way, according as the wind blows. The frame should be made moveable along the wall, that when a tree has been *forced* one year, the frame may be removed to another, and so on, that the trees may be each of them *forced* only once in three years, at which rate they will last a long time. They must be always well-grown trees that are chosen for *forcing*, for young ones are soon destroyed, and the fruit that is produced from them is never so well tasted. The fruits most proper for this management are the avant, or small white nutmeg, the Alberman, the early Newington, and the brown nutmeg peaches; Mr. Fairchild's early, and the elruge and Newington nectarins; the malcaline apricot, and the May-duke and May-cherry. For grapes, the white and black sweet-water are the properest; and of gooseberries, the Dutch white, the Dutch early green, and the walnut gooseberry; and the large Dutch white, and large Dutch red currants.

The dung, before it is put to the wall, should be laid together on a heap for five or six days, that it may heat uniformly through; and when thus prepared, it must be laid four feet thick at the base of the wall, and go sloping up, till it is two feet thick at the top. It must be laid at least within three or four inches of the top of the wall, and when it sinks, as it will sink two or three feet, fresh dung must be laid; for the first heat will do little more than just swell the blossom-buds. The covering of the trees with glasses is of great service, but they should be taken off to admit the benefit of gentle showers to the trees, and the doors at the ends should be either left entirely open, or one or both of them opened, and a mat hung before them, at once to let the air circulate and to keep out the frosts.

The dung is never to be applied till toward the end of November, and three changes of it will be sufficient to ripen the cherries, which will be very fine in February. As to the apricots, grapes, nectarines, peaches, and plums, if the weather be mild, the glasses are to be opened to let in sunshine or gentle showers.

If a row or two of scarlet strawberries be planted at the back of the frame, they will ripen in February, or the beginning of March; the vines will blossom in April, and the grapes will be ripe in June.

It should be carefully observed not to place early and late ripening fruits together, because the heat necessary to force the late ones will be of great injury to the early ones, after they have fruited.

The mastculine apricot will be ripe in the beginning of April, the early nectarines will be ripe about the same time, and the forward sort of plums by the latter end of that month. Gooseberries will have fruit fit for tarts in January or February, and will ripen in March, and currants will have ripe fruit in April.

The trees need not be planted so distant as these walls as at others, for they do not shoot so freely as in the open air: if they are nine feet asunder it is sufficient. They should be pruned about three weeks before the heat is applied. See HOT-*Bed*.

FORCING *pump*. See PUMP.

FORDICIDA, in *Antiquity*, a religious feast among the Romans, held on the fifteenth of April: thus called from the Latin *fordus*, *a cow big with calf*; and *cædo*, *I slay*, or *sacrifice*; because such cows were herein sacrificed to the goddess Tellus, or the earth.

Fordus, *a cow with calf*, is formed, according to Ovid, from *fero*, *I bear*; or rather, as Scaliger and Salmasius imagine, from the Greek φορδος, φορδος, the same.

Varro writes, that there were several of these cows sacrificed in the Curiæ. And Livy and Halicarnassæus relate that there was one in each Curia; to that there were thirty in all; which is confirmed by Ovid, Fastor. lib. iv. ver. 631.

The *fordicidia* were first instituted by Numa, on occasion of a general barrenness among the cattle. Ovid gives a particular description of the ceremony, in the passage above quoted: he adds, that part of these cows were sacrificed in the temple of Jupiter; that is, in the Capitol.

FORE, applied to a ship, denotes all that part of a ship's frame and machinery which lies near the stem.

FORE *and aft* is used for the whole ship's length, or from end to end.

FORE-*bowline* is the BOWLINE of the *fore*-sail.

FORE-*castle of a ship*, is a short deck placed in the *fore* part of the ship, above the upper deck. See *Tab. Ships*, *fig.* 2, *let.* BC, N° 23.

It is usually terminated, both before and behind, by a breast-work in wealth of war; the foremost end forming the top of the HEAD-*head*, and the hind-part reaching to the after-part of the fore-chains.

FORE-*cun-harpings* are those that are used to brace in the upper part of the *fore*-shrouds. See CAT-*harpings*.

FORECLOSED, in our *ancient Law-books*, signifies barred, shut out, or excluded for ever: as, when the equity of redemption on MORTGAGES is barred.

FOREFANG, or FORETENO, in *our old Writers*, is the taking of provision from any one in fairs or markets, before the king's purveyors are served with necessaries for him.

The word is Saxon, compounded of *fore*, *ante*, and *fangen*, *prendere*.

FORE-*foot of a ship*, is a piece of timber that terminates the keel at the *fore* end. It is connected by a scarf to the extremity of the keel, of which it makes a part; and the other end of it, which is bent upwards into a kind of knee or crotch, is fastened to the lower end of the stem, of which it makes a part, being also called the *gripe*.

FOREFOOT, in the *Sea-Language*, is when one vessel sails or lies across another's way.

As if two ships being under sail, and in ken of one another, one of them lies in a course with her stern so much weather of the other, that if both hold on, the windward ship will run a-head of the other; such ship is said to lie with the other's *forefoot*.

Though, as soon as she has passed, they say, she is go'e out a-head.

FOREGAVEL, *forgabulum*, in *our old Writers*, is used for a small reserved rent in money, or quit-rent.

FOREGOERS, in *our old Writers*. The king's purveyors were thus called from their *going before*, to provide for his houshold. 36 Edw. III. 5.

FOREHEAD. *Wounds of the* FOREHEAD. After a wound in this part is cleanſed from grumous blood and extraneous bodies, if any were left there, it ſhould be dreſſed with balſam of Peru, or ſome other vulnerary balſam; the lips of the wound are then to be kept together by long ſlips of ſticking plaiſter, and over this a vulnerary plaiſter is to be laid. Where the wound is large, theſe plaiſters will not be ſufficient to bring on an even cicatrix; therefore, to forward this end, the wound ſhould be ſprinkled with a compound powder of comfrey-root and gum tragacanth and arabic, and with gum ſarcocolla in powder; and then the plaiſters, compreſſes, and proper bandages, are to be applied. The bloody future is never to be uſed in any wound of the face if it can be avoided, becauſe the ſtitches increaſe the number of the ſcars. If a wound of the *forehead* is made in a ſtraight line, the uniting bandage will be of great ſervice in forming a fine cicatrix: but if the *forehead* is wounded tranſverſely, and the fibres of the frontal muſcle are divided, it occaſions a great deformity; for the power of lifting up the eye-brows, and of contracting the ſkin of the *forehead* ceaſes. In this caſe, after cleaning the wound, it is beſt to unite it with a ſtitch or two, dreſſing it with a vulnerary balſam, and laying on ſticking plaiſters, ſecuring all with a proper bandage, and enjoining the patient to keep himſelf ſtill. In young and healthy perſons, the fibres of the muſcles join and unite when this method is uſed, without coming to a ſuppuration. Heiſter's Surg. p. 78.

FORE-*boats of a ſhip*. See BREAST-*boats*.

FORE-*doors*. See DOORS.

FORE-*ſpar-bits*, in a *Ship*. See BITS.

FOREIGN, ſomething extraneous, or that comes from abroad.

The word is formed from the Latin *foris*, *doors*; or *foris*, *out of doors*; or *forum*, *market*, &c.

Foreign miniſter, *foreign* prince, *foreign* goods, &c. are thoſe belonging to other nations. See MINISTER, &c.

Foreign to the purpoſe, ſignifies a thing remote or impertinent.

Matter is *foreign* to the idea of ſpace, i. e. it is not inherent therein, but adventitious thereto.

Foreign plants are particularly called EXOTICS. *Foreign foſſils*, ſee FOSSIL. *Foreign motion*, ſee MOTION. *Foreign canons*, ſee CANON.

In ſome univerſities they give the appellation *foreign doctors*, *doctores forenſes*, to ſuch as do not reſide in the place, or the univerſity; but take degrees to go and live elſewhere, and in other countries.

In the life of St. Paul, biſhop of Verdun, written by an anonymous author, and publiſhed from a MS. about four hundred years old, by Bollandus, we meet with *forenſis preſbyter*, for a prieſt who lives in another part. The ſame Bollandus notes, that St. Ambroſe uſed the word *forenſis* for exterior.

FOREIGN, or FORAINE *Traite*, is a duty belonging to the king of France, of one-twentieth of the value of all goods imported, or exported out of the kingdom.

FOREIGN, is uſed in *Law*, in ſeveral ſenſes, and joined with divers ſubſtantives. Thus,

FOREIGN *anſwer*, is ſuch an anſwer as is not triable in the county where it is made.

FOREIGN *attachment*. See ATTACHMENT.

FOREIGN *bill of exchange*. See BILL.

FOREIGN *matter*, in *Law*, is matter triable in another county; or matter done in another county.

FOREIGN *appoſer*, or *appoſer*, is an officer in the exchequer, to whom all ſheriffs or bailiffs do repair to be appoſed by him of their green wax, after they are appoſed of their ſums out of the pipe office; and who from thence draws down a charge upon one of them to the clerk of the pipe.

His buſineſs is to examine the ſheriff's eſtreats with the record, to aſk the ſheriff what he ſays to every particular ſum therein.

FOREIGN *plea*, is a refuſal of the judge as incompetent, becauſe the matter in hand was not within his precinct.

FOREIGN *ſeamen*, ſerving two years on board Britiſh ſhips, whether of war, trade, or privateers, during the time of war, ſhall be deemed natural born ſubjects. But the perſons ſo naturalized are not capable of being of the privy council, or members of parliament, or of taking any place of truſt, civil or military, or to have any grant from the crown of lands. Stat. 13 Geo. II. cap. 3. ſect. 2.

FOREIGN *ſervice*, is ſuch ſervice whereby a mean lord holdeth of another, without the compaſs of his own fee; or that which a tenant performeth, either to his own lord, or to the lord paramount, out of his own fee.

FOREIGN *ſervice* is alſo uſed to denote military ſervice performed to *foreign* ſtates. The ſtat. 3 Jac. I. cap. 4. makes it *felony* for any perſon to go out of the realm to ſerve any *foreign* prince, without having firſt taken the oath of allegiance before his departure: and it is alſo felony for any gentleman, or perſon of higher degree, who hath borne any office in the army, to go out of the realm to ſerve ſuch *foreign* prince or ſtate, without previouſly entering into a bond with two ſureties not to be reconciled to the ſee of Rome, or enter into any conſpiracy againſt his natural ſovereign. And by ſtat. 9 Geo. II. cap. 30. enforced by 29 Geo. II. cap. 17. if any ſubject of Great Britain ſhall enliſt himſelf, or any perſon ſhall procure him to be enliſted, in any *foreign* ſervice, or detain or embark him for that purpoſe, without licence under the king's manual, he ſhall be guilty of felony without benefit of clergy; but if the perſon ſo enliſted or enticed, diſcover his ſeducer within fifteen days, ſo that he may be apprehended and convicted of the ſame, he ſhall be indemnified. By ſtat. 29 Geo. II. cap. 17. to ſerve under the French king, as a military officer, is felony without benefit of clergy; and to enter into the Scotch brigade, in the Dutch ſervice, without taking the oaths of allegiance and abjuration, incurs a forfeiture of five hundred pounds.

FOREIGNERS are the natural born ſubjects of ſome foreign prince. *Foreigners* reſiding ſeven years in the Britiſh plantations without any longer abſence than two months at one time, and taking the oaths, are to be deemed natural born ſubjects. But, excepting Quakers and Jews, all other perſons muſt receive the ſacrament in ſome proteſtant or reformed congregation in Great Britain, or the colonies; a certificate whereof muſt be produced at the time of taking the oaths. 13 Geo. II. cap. 7. ſect. 2. See NATURALIZATION.

FOREJUDGED *the court*, is when an officer of any court is baniſhed, or expelled the ſame, for ſome offence; or for not appearing to an action by bill filed againſt him: in which latter caſe, he is not to be admitted to officiate, till he appear to the bill. Anno 2 Hen. IV. cap. 8.

He ſhall loſe his office, and be *forejudged* the court, &c. *Forjudicare interdum eſt male judicare*. Spel.

FOREJUDGER, in *Law*, ſignifies a judgment, whereby a man is deprived, or put by a thing in queſtion.

FORELLA, in *Ichthyology*, a name given by Figulus and others to the trout.

FORE-*knight*, in the *Sea-language*, a piece of wood, carved in figure of a man's head, and faſt bolted to the beams upon the ſecond deck.

FORELAND, or FORENESS, in *Navigation*, a point of land jutting out into the ſea.

FORELAND, in *Fortification*, is a ſmall ſpace of ground between the wall of a place, and the moat; called alſo BERME, and *lineta*.

FORELOCKS, in a *Ship*, are little flat wedges, like pieces of iron, uſed at the ends of bolts, to keep them from flying out of the holes.

FORELOIN, among *Hunters*, is when a hound going before the reſt of the cry, meets chace, and goes away with it.

FORELORN *hope*, in an *Army*, an almoſt obſolete expreſſion. See ENFANS *perdus*.

FORE-*maſt of a ſhip*, is a round large piece of timber, ſeated in her fore-part, on which is born the fore-ſail, and fore top-ſail-yard. See *Tab. Ship. fig.* 1. N° 81. See MAST.

FORE-*maſt-men*, in a *Man of War*, thoſe on board that take in the top-ſails, ſling the yards, furl the ſails, browſe, triſe, and take their turn at the helm, &c.

FORENSIC *ſervice*. See SERVICE and FOREIGN.

FORENSIS *togo*. See TOGA.

FORE-*rake*, in *Sea-language*. See RAKE.

FORE-*reach*, in *Sea-language*. The ſeamen ſay one ſhip *fore-reaches* upon another, when both ſailing together, ſhe ſails better, or outgoes the other.

FORE-*ſail*, the ſail of the fore-maſt. See SAIL.

FORESCHOKE, *dereliction*, anciently ſignified as much as *forſaken* in modern language.

It is eſpecially uſed in one of our ſtatutes, for land or tenements ſeized by the lord, for want of ſervices due from the tenant; and ſo quietly held and poſſeſſed beyond the year and day.

As if we ſhould ſay, that the tenant, who ſeeing his lands or tenements taken into the lord's hand, and poſſeſſed ſo long, takes not the courſe appointed by law to recover them, does, in due preſumption of law, diſavow or forſake all the right he has to them. In which caſe, ſuch lands ſhall be called *foreſchoke*, ſays the ſtat. 10 Ed. II. cap. 1.

FORE-*ſhrouds*. See SHROUDS.

FORESKIN. See PREPUCE.

FORE-*ſtay*. See STAY.

FOREST, *ſylva*, in *Geography*, a great wood; or a large extent of ground covered with trees.

The word is formed of the Latin *foreſta*, which firſt occurs in the Capitulars of Charlemagne, and which itſelf is derived from the German *forſt*, ſignifying the ſame

thing

thing. Spelman derives it from the Latin *foris roſtat*, by reaſon *foreſts* are out of towns. Others derive *foreſta a feris*, q. d. *foreſta, quod ſit tuta ſtatio ferarum*, as being a ſafe ſtation, or abode, for wild beaſts.

The Caledonian and Hercynian *foreſts* are famous in hiſtory. The firſt was a celebrated retreat of the ancient Picts and Scots: the latter anciently poſſeſſed the greateſt part of Europe; particularly Germany, Poland, Hungary, &c. In Cæſar's time it extended from the borders of Alſatia and Switzerland to Tranſylvania, and was computed ſixty days journey long, and nine broad: ſome parts of cantons thereof are ſtill remaining. The *foreſt* of Dean in Glouceſterſhire, is famous for the iron works therein.

The ancients adored *foreſts*, and imagined a great part of their gods to reſide therein: temples were frequently built in the thickeſt *foreſts*, the gloom and ſilence whereof naturally inſpired ſentiments of devotion, and turned men's thoughts within themſelves.

For the like reaſon, the ancient Druids made *foreſts* the place of their reſidence, and performed their ſacrifices, inſtructed their youth, and gave laws therein. See DRUIDS.

FOREST, in a *Law-ſenſe*, is defined a certain territory of woody grounds and fruitful paſtures, privileged for wild beaſts and fowls of *forſt*, chace, and warren, to reſt and abide in, under the protection of the king, for his recreation and delight; bounded with unremoveable marks and meres, either known by matter of record or preſcription; repleniſhed with wild beaſts of venery, or chace, and with great coverts of vert for ſuccour of the ſaid beaſts: for preſervation and continuance whereof, with the vert and veniſon, there are certain peculiar laws, privileges, and officers.

The properties and characters of a *foreſt* are, firſt, that it cannot be in the hands of any but the king: becauſe none elſe had power to conſtitute ſuch commiſſions as are neceſſary to the being of a *foreſt*, beſide the king; as, particularly, that of juſtice in eyre of the *foreſt*.

And yet the abbot of Whitby had a *foreſt* by grant of king Henry II. and king John, with all officers incident thereto.

The ſecond character is the courts belonging thereto, which are, the *juſtice-ſeat*, and the *regard*, held every third year; the *ſwanimote*, held thrice every year; and the *attachment*, once every forty days.

The third characteriſtic is the officers belonging thereto, for preſervation of the vert and veniſon; as the juſtices of the *foreſt*, the warder of keeper, ranger, verderers, foreſters, agiſtors, regarders, bailiffs, beadles, &c. See each under its proper article, JUSTICE *of the foreſt* KEEPER, &c.

But the moſt eſſential mark of a *foreſt* is the ſwanimote, which is no leſs incident thereto than the court of pye-powder to a fair. If that fail, it ceaſes to be a *foreſt*, and commences a chace. See SWANIMOTE.

The way of making a *foreſt* is thus: certain commiſſioners appointed under the great ſeal, view the ground intended, and fence it round; this being reported in chancery, the king cauſes it to be proclaimed throughout the county where the land lies, that it is a *foreſt*, and is thenceforth to be governed by the laws of the *foreſt*; and prohibits all perſons from hunting therein, without his leave.

New *Foreſt* in Hampſhire, hiſtory tells us, was made by the deſtruction of twenty-two pariſh-churches, and all the villages, manors, chapels, &c. for the ſpace of thirty miles together. Beſide New *Foreſt*, there are now ſubſiſting ſixty-eight *foreſts* in England, thirteen chaces, and eight hundred parks.

Our ancient Norman kings were the firſt who incloſed *foreſts*, and ſettled the juriſdiction thereof. In the courſe of a few reigns from the Conqueſt, no leſs than ſixty-eight *foreſts* were incloſed; the ſtricteſt laws were made to ſecure them, and the ſevereſt penalties inflicted on all treſpaſſers thereon.

William the Conqueror decreed the eyes of any perſon to be pulled out, who took either a buck or boar: William Rufus made the ſtealing of a doe a hanging matter; the taking of a hare was fined at 20s. and a coney at 10s. Eadmer adds, that fifty perſons of fortune, being apprehended by that laſt prince for killing his bucks, were forced to purge themſelves by the fire of ordeal, &c.

Henry I. made no diſtinction between him who killed a man and him who killed a buck; and puniſhed thoſe who deſtroyed the game, though not in the *foreſt*, either by forfeiture of their goods, or loſs of limbs; though Henry II. remitted it for a temporary impriſonment.

Richard I. revived the old diſcipline of gelding and pulling out the eyes of thoſe convicted of hunting in the *foreſt*: but he afterwards relaxed a little, and was contented to make ſuch convicts abjure the realm, or be committed, or pay a fine.

FOREST, *aſſize of the.* See ASSIZE.

FOREST, *charter of the.* See CHARTER *of the foreſt*.

FOREST, *drift of the.* See DRIFT.

FOREST, *foot of the.* See FOOT.

FOREST, *keeper of the.* See KEEPER.

FOREST, *perambulation of the.* See PERAMBULATION.

FOREST, *repoſition of the.* See REPOSITION.

FOREST, *waſte of the.* See WASTE.

FOREST is alſo uſed adjectively. The *foreſt* cities of the empire are four cities ſituate in the ancient Black *Foreſt*, or Sylva Nigra, a part of the ancient Hercynian *Foreſt*, viz. Rhinfield, Waldſhuft, Seckingen, and Lauffembourg. But now, ſince the bounds of the Black *Foreſt* are contracted, theſe cities are out of the limits thereof.

FOREST-*laws*. The *foreſt* laws are peculiar laws, different from the common law of England.

Before the making of Charta *de Foreſta*, in the time of king John and his ſon Henry III. confirmed in parliament by 9 Henry III. offences committed therein were puniſhed at the pleaſure of the king, in the ſevereſt manner. By this charter, many *foreſts* were diſafforeſted and ſtripped of their oppreſſive privileges, and regulations were made for the government of thoſe that remained; particularly, killing the king's deer was made no longer a capital offence, but only puniſhed by fine, impriſonment, or abjuration of the realm; yet even in the charter there were ſome grievous articles, which the clemency of later princes have ſince by ſtatute thought fit to alter *per aſſiſus* foreſtæ.

And to this day, in treſpaſſes relating to the *foreſt*, *volantas reputabitur pro facto*; ſo that if a man be taken hunting a deer, he may be arreſted as if he had taken a deer. The foreſter may take and arreſt a man, if he be taken either at dog-draw, ſtable-ſtand, bock-bear, or bloody-hand, notwithſtanding that three of theſe be only preſumptions. See DOG-*draw*, STABLE-*ſtand*, &c. See alſo BLACK *act*.

FORESTING. Many are wholly averſe to pruning *foreſt*-trees; but though it is to be done with care, and under proper regulations (*ſee* LOPPING), yet it is by no means to be wholly omitted. It may be obſerved in *foreſts* and large woods, that for one tree which thrives well, there are twenty that grow ſaulty, and all this is owing to the want of pruning or lopping in a proper manner; for this, when wiſely executed, is a renewal of their age, and of their growth too; the want of it being what occaſions trees to run out into ſuckers, and to load themſelves with uſeleſs boughs, which draw away the ſap from the upper part, and make it grow knotty and diſtempered, and uſually covered with moſs.

If a tree grow crooked, the buſineſs of the owner is to cut it off ſloping at the crooked place, and nurſe up ſome young bough that grows upright from that part, and it will make it a ſtraight body. This is not to be done when trees are very large, but the careful owner will not ſuffer them to grow very large without doing it. Mortimer's Huſbandry, vol. ii. p. 84.

There is alſo an other caution, which is, that ſoft woods do not bear this heading ſo well as the harder, and the beech in particular is leſs able to bear it than any other. If young trees grow but a little crooked, they may be cured by only ſhreding up the branches while young, all the way up the body till paſt the crooked part. When cattle have cropped any of the ſhoots of young trees, they ſhould be cut off cloſe to the body, for they not only never grow well after it, but the cattle uſually leave a drivel where they have bitten, which ſometimes occaſions a rot of the branch, and endangers the whole tree. The beſt time for pruning young *foreſt*-trees is in February; and it ſhould be done where there is occaſion every year, or at the utmoſt every ſecond year, ſo that the tree may be able to overgrow the knot, and the place not liable to put out ſuckers, becauſe the ſap has had no great recourſe to it. When it is neceſſary to cut off a bough of any bigneſs, there muſt always be given a chop or two underneath, oppoſite to the part where it is cut above, otherwiſe the weight of the bough, in its fall, is apt to ſtrip off the bark from the remaining ſtump, to the great detriment of the tree. When trees are kept for pollards, they muſt be regularly lopped every two years; for if the branches are ſuffered to grow longer than that, they are apt to be ſaulty at the wound when cut off, and to let in water, the conſequence of which will be the decay of the tree, and it can no more bear any great quantity of branches at top.

The general growth of trees in thickneſs of the body, is from one inch to two inches in a year. The large and ſmall increaſe much in the ſame proportion in this reſpect, if they are in a like thriving condition. The goodneſs of ſoil will make a great difference in this growth, as has been experienced by Mortimer, who obſerved, that the common increaſe of the oak is about an inch and a quarter in thickneſs in the body in a year; but a large

ons that grew in one of his own ploughed fields, where the earth was tilled and manured every year, and that often had cattle lying under it, and dunged about its roots, grew annually no less than four inches in thickness. This shews the great advantage of digging about the roots of trees, and dunging them, and may serve as a hint for a very practicable method of increasing the growth of trees on occasion. The killing of weeds that grow about the roots of trees, is one great method of hastening the growth; but there is an error which some have run into on this principle, that is not to be carefully avoided. Those people observing the great damage that weeds do the trees, have supposed that shrubs and underwood in hedges and coppices do the same; but this is a mistake. Experience shews, that *wood*-trees thrive better and grow faster in coppices than when they stand single; and it is certain that, next to digging and dunging about the roots, the growth of underwood about the tree is the best method of promoting its increase; these shrubs keeping the earth moist about the roots of the tree, and mingling all the earth about with their falling leaves and rotten branches, which break off at times, and which are the richest of all manure: a little rotten wood blended among even a bad soil, converting it into the nature of garden-mould. Mortimer's Husbandry, vol. ii. p. 86. See TREES and TIMBER.

FOREST-*trees, transplanting of.* See TRANSPLANTING.

FORE-*staff*, an instrument used at sea, for taking the altitudes of heavenly bodies.

The *fore-staff*, called also *cross-staff*, takes its denomination hence, that the observer, using it, turns his face towards the object, in contradistinction to the back-staff, where he turns his back to the object.

The *fore*, or cross staff, represented in *Tab. Navigat. fig.* 12. consists of a strait square staff, AB, graduated like a line of rangents, and tope crosses, or vanes FF, EE, DD, CC, which slide thereon. The first and shortest of these vanes, FF, is called the *ten cross*, or *vane*, and belongs to that side of the instrument, whereon the divisions begin at three degrees, and end at ten. The next longer vane, EE, is called the *thirty cross*, belonging to that side of the staff, wherein the divisions begin at ten degrees, and end at thirty, called the *thirty staff*. The next vane, DD, is called the *forty cross*, and belongs to the side where the divisions begin at twenty degrees, and end at fifty. The last, and longest, CC, called the *ninety cross*, belongs to the side whereon the divisions begin at thirty degrees, and end at ninety.

FORE-*staff, use of the.* The great use of this instrument is to take the height of the sun, and stars, or the distance of two stars: and the ten, thirty, sixty, or ninety crosses, are to be used according as the altitude is greater, or lesser; that is, if the altitude be less than ten degrees the ten cross is to be used; if above ten, but less than thirty, the thirty cross is to be used, &c.

Note, for altitudes greater than thirty degrees, this instrument is not so convenient as a quadrant, or semicircle.

FORE-*staff, to observe an altitude by the.* Apply the flat end of the staff to your eye, and look at the upper-end of the cross for the centre of the sun, or star, and at the lower end for the horizon. If you see the sky, instead of the horizon, slide the cross a little nearer the eye; and if you see the sea, instead of the horizon, slide the cross farther from the eye: and thus continue moving till you see exactly the sun or star's centre by the top of the cross, and the horizon by the bottom thereof.

Then the degrees and minutes, cut by the inner edge of the cross upon the side of the staff, peculiar to the cross you use, give the altitude of the sun or star.

If it be the meridian altitude you want, continue your observation as long as you find the altitude increase, still moving the cross nearer to the eye.

By subtracting the meridian altitude thus found, from ninety degrees, you will have the zenith distance.

To work accurately, an allowance must be made for the height of the eye above the surface of the sea, viz. for one English foot, 1 minute; for five feet, 2¼; for ten feet, 3¼; for twenty feet, 5; for forty feet, 7, &c.

These minutes subtracted from the altitude observed, and added to the zenith distance observed, give the true altitude, and zenith distance.

FORE-*staff. To observe the distance of two stars, or the moon's distance from a star, by the* FORE-*staff.* Apply the instrument to the eye, and looking to both ends of the cross, move it nearer, or farther from the eye, till you see the two stars; the one on the one end, and the other on the other end of the cross: then the degrees and minutes cut by the cross on the side proper to the vane in use, give the stars distance.

FORESTAGE, FORESTAGIUM, *in our Ancient Customs*, an obsolete duty, or service, paid by the foresters to the king. In Britany, Lobineau observes, the office of foresters was held by gentlemen of the first rank, who for their *forestage* were obliged to furnish the lord, when he kept open house, with cups and spoons.

FORESTAGE also seems to have been used for a duty payable to the king's foresters. *Et sint quieti de thelonio, & passagio, & de forestagio, &c.* Chart. Edw. I.

It may likewise be taken for a right to use the forest, or a taking of reasonable REMORES.

FORESTAL, or FORESTAL, in Domesday write FORISTEL, is an intercepting in the highway; or stopping, or even insulting a passenger thereon.

The word is framed of the Saxon *fore, before*, and *stal, station*. In the laws of Henry I. the sense of the word is thus explained: *forestal est, si quis ex transverso incurrat, vel in viam expellat, & injuriat inimicum suum.*

FORESTALLER, a person who *forestalls* the market, or buys up goods upon the road.

FORESTALLING, the buying or bargaining for corn, cattle, or other merchandize, by the way, before it reaches the market, or fair, to be sold; or by the way, as it comes beyond the seas, or otherwise, toward any city, port, haven, or creek, of this realm, with design to take advantage thereof, and sell it again at a more advanced and dear rate.

Fleta says, it signifies *obstructionem viæ, vel impedimentum transeuntis & fugæ averiorum.*

By the 5th and 6th Edw. VI. cap. 14. any buying or contracting to have merchandize, victuals, or other thing whatsoever, in the way, coming by land or water to any fair or market, or to any port, &c. to be sold, or causing the same to be bought; or dissuading people by word, letter, or otherwise, or otherwise from bringing such things to market; or persuading them to enhance the price after they are brought thither: is *forestalling*: and the party guilty of any offence of *forestalling*, &c. upon conviction at the quarter sessions by two witnesses, or bill, information, confession, &c. shall, for the first offence, lose the goods so bought, or the value of them, and suffer two months imprisonment: for the second offence, he shall forfeit double the value, and be imprisoned six months: and for the third offence, he shall forfeit all his goods, be set upon the pillory, and be imprisoned at the king's pleasure.

FORESTALLING is particularly used in Crompton, for stopping a deer broken out of the forest, and preventing its returning home again; or, a lying between him and the forest in the way he is to return.

FORESTER, a sworn officer of the forest, appointed by the king's letters patent to walk the forest, and watch the vert and venison; as also to attach and present all trespasses against both, within his bailiwick or walk, to the forest-courts, to be punished according to their office.

Though the letters patent of a *forester* be ordinarily only granted *quamdiu bene se gesserit*; yet they are granted to some and their heirs, who are hereby called *foresters in fee*.

Sir William Temple relates, that the Franks having subdued all Gaul, their princes reduced Flanders into a kind of government, and gave the quality of *forester*, with part of the province, to the bravest of their captains. This quality of lord *forester* held till the time of Charlemagne, or, according to others, of Charles the Bald, in whose time Flanders being erected into a county, the title of *forester* was changed into that of count.

FORESTED *ore*, in *Mining*, is ore got out of earth and dirt that has been walled, and ore taken from it before.

FORE-*top of a ship*. See TOP.

FORE-*top-mast* is half the length of the fore-mast (see *Ship, fig.* 1. tt. 102.) and the fore-top-gallant-mast half the length of the *fore-top-mast*. See TOP-*mast* and MAST.

FORE-*tooth*. Striking out the *fore-tooth* is a *mayhem*.

FORE-*yard*. See YARD.

FORFEITURE originally signifies a transgression or offence against some penal law.

The word is formed of the base Latin *forisfactura*, whence *forfaitura*, and *forfaiture*, and the French *forfait*. *Forisfacturn* comes of *forisfacere*, which, according to Isidore, signifies *to hurt, or offend*. *Sacere extra rationem*; and which is not improperly derived of *foris*, *out*, and *facere*, *to do*, q. d. an action out of rule, or contrary to the rules.

But with us, it is now more frequently used for the effect of such transgression, or the losing some right, privilege, estate, honour, office, or effects, in consequence thereof, than for the transgression itself; as *forfeiture of wherry, forfeiture of goods*, &c. A fee becomes vacant by the *forfeiture* or rebellion of the vassal.

Goods *forfeited*, and goods confiscated, differ: those which have a known owner, who has committed some offence, whereby he loses his goods, are said to be *forfeited*: those which an offender disowns, as not his own, and which are not claimed by any other, are said to be confiscated,

confiscated, stat. 25 Edw. III. Add, that *forfeiture*, or *forfeit*, is more general; and confiscation more particular, being principally used for such as *forfeit* only to the king's exchequer.

FORFEITURE, *full. plena forisfactura*, called also *plena vita*, is a *forfeiture* of life and member, and all else that a man has.

This obtains in criminal cases, as where a person is attainted of treason, felony, &c. There is also a *forfeiture* of lands, &c. in civil cases. There are various degrees and various means, whereby lands, tenements, and hereditaments, may be *forfeited*. 1. By crimes and misdemeanors: of theft, the principal offences that induce a *forfeiture* of lands and tenements to the crown, are treason, felony, misprision of treason, præmunire; drawing a weapon on a judge, or striking any one in the presence of the king's principal courts of justice, and pontifical consistory, or non-observance of certain laws enacted in restraint of papists. 2. By ALIENATION, contrary to law, which may be in MORTMAIN; to an alien, on account of his incapacity to hold the lands so alienated; and by particular tenants, when the alienations are greater than the law entitles them to make, and divest the remainder or reverſion; in which case they become *forfeitures* to him whose right is hereby injured: there is also an alienation by DISCLAIMER. 3. By non-preſentation to a benefice, when the *forfeiture* is denominated a LAPSE. 4. By SIMONY. 5. By breach or non-performance of CONDITIONS, annexed to eſtates, either expreſſed or legally implied. 6. By WASTE. 7. By breach of COPYHOLD cuſtoms. 8. By BANKRUPTCY. Goods and chattels, likewiſe, are totally *forfeited* by conviction of high treaſon, or miſpriſion of treaſon; of petit treaſon; of felony in general, and particularly of felony *de ſe*, and of man-ſlaughter; nay, even by conviction of excuſable homicide; by outlawry for treaſon or felony; by conviction of petit larceny; by flight in treaſon or felony, even though the party be acquitted of the fact; by ſtanding mute, when arraigned of felony; by pretended prophecies, upon ſecond conviction; by owling; by the reſiding abroad of artificers; and by challenging to fight on account of money won at gaming. This *forfeiture* commences from the time of conviction, and not the time of committing the fact, as in *forfeitures* of real property. However, a fraudulent conveyance of chattels, between the time of committing the fact and conviction of the offender, to defeat the intereſt of the crown, is made void by ſtatute 13 Eliz. cap. 5. There are alſo various other *forfeitures* inflicted, by ſpecial ſtatutes, for particular crimes and miſdemeanors; ſome of which are *mala in ſe* or offences againſt the divine law, either natural or revealed; but by far the greateſt part are *mala prohibita*, or ſuch as derive their guilt merely from their prohibition by the laws of the land; ſuch as the *forfeiture* of 40*l.* per month by the ſtat. 5 Eliz. cap. 4. for exerciſing a trade without having ſerved ſeven years apprenticeſhip to it; and the *forfeiture* of 10*l.* by 9 Ann. cap. 23. for printing an almanack without a ſtamp. Blackſt. Com. vol. ii. p. 267, &c. 420, &c. vol. iv. p. 370, &c. 416, &c.

The true reaſon of any *forfeiture* for crimes, ſays judge Blackſtone, is this: that all property is derived from ſociety, being one of thoſe civil rights which are conferred upon individuals, in exchange for that degree of natural freedom, which every man muſt ſacrifice when he enters into ſocial communities: if, therefore, a member of any national community violates the fundamental contract of his aſſociation, by tranſgreſſing the municipal law, he *forfeits* his right to ſuch privileges as he claims by that contract; and the ſtate may very juſtly reſume that portion of property, or any part of it, which the laws have before aſſigned him. Hence, in every offence of an atrocious kind, the laws of England have exacted a total confiſcation of the moveables or perſonal eſtate; and in many caſes a perpetual, in others only a temporary, loſs of the offender's immoveables or landed property: and have veſted them both in the king, who is the perſon ſuppoſed to be offended, being the one viſible magiſtrate in whom the majeſty of the public reſides. Blackſt. Com. vol. i. p. 299.

FORFEITURE *of marriage*, *forisfactura maritagii*, a writ, which formerly lay againſt him, who, holding by knight's ſervice, and being under age, and unmarried, refuſed her whom the lord offered him, without his diſparagement, and married another.

FORFEX, in *Surgery*, a pair of ſciſſars wherewith things may be cut.

The word is ſometimes alſo uſed for pincers, nippers, or pillers; and is often confounded with *forceps*. Blanchard and, after him, Quincy, deſcribes a *forfex* as an inſtrument for drawing teeth.

FORFICULA. See EAR-*wig*.

FORFICULA *marina*, the *ſeaw-wig*, a name given by authors to an inſect frequently found about the ſea-ſhores, and having ſome ſort of external reſemblance to the common *ear-wig*. It is of the ſize of the common *ear-wig*, and is of a mixed colour, of a deep black and a ſilvery white. The ſhoulders are ſomewhat gibbous, the eyes ſtanding cloſe to one another on the ſummit of the head; the antennæ are long and very ſlender. It has eight pair of legs on the anterior part of the body, and eight pair more at the hinder part, and there are three or four briſtles at the tail. It moves about very nimbly, and lives on rocks and among ſtones.

FORFIELD, *in Mining*, is the fartheſt place that a man has wrought in his ground; or the end of a mear above ground.

FORGE properly ſignifies a little furnace, wherein ſmiths, and other artificers in ſeveral kinds, &c. heat their metals red-hot, in order to forge and render them more malleable and manageable on the anvil, &c.

We ſay, a *ſmith's forge*, *ſilverſmith's forge*, *cutler's forge*, *lockſmith's forge*, &c. The *forge* uſed by the ſeveral operaters in iron is very ſimple; we ſhall inſtance in that of the blackſmith, to which all the reſt are reducible.

The hearth, or fire-place, is a maſs of brick, about two feet ſix inches high: the back of the *forge* is built upright to the ceiling, and is incloſed over the fire-place with a hovel, which leads into a chimney, to carry away the ſmoke. In the back of the *forge*, againſt the fire-place, is a thick iron plate, with a taper pipe fixed therein, about five inches long, called the *tuyel*, into which the noſe or pipe of the bellows is received: the ſize of this plate and tuyel is, to proſerve the pipe of the bellows, and the back of the hearth from being burnt. Right before the back, at about two feet diſtance, is the trough, filled with water, to wet the coals with, and thereby increaſe their force, as alſo to quench the iron in. Behind the back of the *forge* is placed the bellows, one of whoſe boards is fixed to, that it moves not, either upward or downward; and to the other is fixed a rope, chain, or even a rod, which riſing perpendicularly, is fixed to a croſs piece, called the *rocker*, which moving on a kind of fulcrum near the middle, ſerves as a handle.

By drawing down this handle, the moveable board of the bellows riſes, and, by a conſiderable weight at the top of its upper ſide, it ſinks down again, and, by this alternate agitation, performs the neceſſary motions of a pair of bellows. See BELLOWS.

Brazers and coppersmiths *forge* differs but little from that already deſcribed; only that it is much leſs, and that nothing is burnt in it but charcoal, the metals uſed by theſe operators not working well with pit-coal.

FORGE is alſo uſed for a large furnace, wherein iron ore, taken out of the mine, is melted down.

But this is not to properly called a *forge* as a furnace.

FORGE is more properly uſed for another kind of furnace wherein the main ore, melted down and ſeparated in a former furnace, and there caſt into ſows and pigs, is heated, and fuſed over again, and beaten afterwards with large hammers, and thus rendered more ſoft, pure, ductile, and fit for uſe.

Of theſe *forges* there are two kinds, which the iron ſucceſſively paſſes through, before it comes to the ſmith.

The firſt is called the FINERY, where the pigs are worked into groſs iron, and prepared for the ſecond, which is called the CHAFERY, where it is farther wrought into bars fit for uſe.

FORGE-*anvils*. See ANVIL.

FORGE, *travelling*, in the *Train of Artillery*, is a kind of portable ſmith's ſhop, by means of which any neceſſary work may be performed on a march, as well as in camp. This kind of *forge* has been formerly fixed in a carriage with two wheels, and wooden ſupporters, to prop the *forge* when uſed; but they are now commonly made with four wheels, ſo that they ſtand more firmly, and are more eaſily removed.

FORGE *for ſhot and balls*, is a place where the balls are made red hot before they are fired off: it is conſtructed about five or ſix feet below the ſurface of the ground, of ſtrong brick-work, and an iron grate, upon which the balls are laid with a large fire under them.

FORGER *of falſe deeds*, ſignifies either him that fraudulently makes and publiſhes falſe writings, to the prejudice of any man's right, or elſe the writ that lies againſt him who commits this offence.

Fitz. Nat. Br. fol. 69. b. ſays, that a writ of deceit lies againſt him who commits this offence; and the penalty of it is declared in the ſtat. 5 Eliz. cap. 14.

FORGERY, in *Law*, is where a perſon fraudulently makes and publiſhes falſe writings, to the prejudice of another man's right: and *forgery* is either at common law, or by ſtatute, puniſhable by indictment, information, &c. But there can be no *forgery* where no one can be prejudiced

by it, but the perſon doing it. 1 Salk. 375. *Forgery*, by common law, extends to a falſe and fraudulent making or altering of a deed or writing, whether it be matter of record, or any other writing, deed, or will. 3 Inſt. 169. 1 Roll. abr. 65. Not only where a falſe deed is made, but where a fraudulent alteration is made of a true deed in a material part of it, it is *forgery*.

By a late act, an offender, *forging* or counterfeiting any deed, will, bond, bill of exchange, note, or acquittance for money, or any indorſement or aſſignment of a bill, &c. with intent to defraud any perſon, or publiſhing ſuch falſe deed, &c. to be true, knowingly, ſhall be guilty of felony, and ſuffer death as a felon; but not to work any corruption of blood, &c. Stat. 2 Geo. II. cap. 25 7 Geo. II. cap. 22.

By an act paſſed in 1778, explaining the former laws on the ſubject of *forgeries*, it is enacted, that making or forging, &c. or cauſing to be made or forged, &c. or aſſiſting in making or forging, &c. any acceptance of any bill of exchange, or the number or principal ſum of any accountable receipt for any note or bill, or any warrant or order for payment of money or delivery of goods, with intention to defraud any corporation, or publiſhing as true any ſuch forged acceptance, &c. incur the guilt of felony, and the puniſhment of death, without benefit of clergy. 18 Geo. III.

FORGING, in the *Mechanic Arts*, the act of beating or hammering iron on an anvil, after having firſt made it red-hot in the *forge*, in order to extend it into various forms, and faſhion it into works.

Iron is hammered and forged two ways; either by the force of the hand, in which there are uſually ſeveral perſons employed, one of them turning the iron, and hammering likewiſe, and the reſt only hammering.

Or, it is done by the force of a water-mill, which raiſes and works ſeveral huge hammers, beyond the force of man, under the ſtrokes whereof the workmen preſent large lumps or pieces of iron, which are ſuſtained, at one end, by the anvils, and, at the other, by iron chains faſtened to the cieling of the forge.

This laſt way of *forging* is only uſed in the largeſt works, as anchors for ſhips, &c. which uſually weigh ſeveral thouſand pounds. For the lighter works, a ſingle man ſuffices to hold, heat, and turn, with one hand, while he ſtrikes with the other. Each purpoſe for which the work is deſigned, requires its proper heat. If it be too cold, it will not feel the weight of the hammer, as the ſmiths call it, i. e. it will not ſtretch or give way; and, if it be too hot, it will red-fear, i. e. it will break or crackle under the hammer.

The ſeveral heats the ſmiths give to their irons are, 1. A blood-red heat. 2. A white-flame heat. 3. A ſparkling or welding heat.

FORGING *over*, in *Sea-language*, denotes the act of forcing a ſhip violently over a ſhoal, by the effort of a great quantity of ſail.

FORK-*tail*, among the *Fiſhermen of England*, a name given to the ſalmon, while in the fourth year's growth, and not yet come to what they call a SALMON.

FORKED *beard*, *great*, in *Ichthyology*, a name given to the coaſt of Cornwall to the BLENNIUS *phycis* of Linnæus.

FORKED *heads*, among *Hunters*, thoſe horns of deer which bear two croches on the top, or which have their croches doubled.

FORLANA, in the *Italian Muſic*, a ſort of dance much in uſe among the Venetians. See SALTARELLA.

FORLET *land*, ſuch land in the biſhoprick of Hereford, as was granted or leaſed. *Ham epiſcopus in epiſcopatu ſleterii*, that the ſucceſſor might have it for his preſent income. But now that cuſtom is diſuſed, and the ſame lands are granted, as others, by leaſe; yet they ſtill retain the name.

FORLORN, or FORLORN-*hope*. See ENFANS *perdus*.

FORM, FORMA, in *Phyſics*, denotes the manner of being peculiar to each body; or that which conſtitutes it ſuch a particular body, and diſtinguiſhes it from every other.

Mr. Harris uſes the term *form* likewiſe in another ſenſe, as an efficient animating principle; to which he ſuppoſes Ovid to refer in the firſt lines of his Metamorphoſis,

In nova fert animus mutatas dicere formas
Corpora——

Theſe animating *forms* are of themſelves no objects either of the ear, or of the eye; but their nature or character is underſtood in this, that were they never to exert their proper energies on their proper ſubjects, the marble on which the ſculptor exerciſes his art would remain for ever ſhapeleſs, and the harp from which the harper calls forth ſounds would remain for ever ſilent.

Thus, alſo, the animating *form* of a natural body is neither its organization, nor its figure, nor any other of thoſe inferior *forms*, which make up the ſyſtem of its viſible qualities; but it is the power, which is yet able to produce, preſerve, and employ theſe. It is the power, which firſt moves, and then conducts that latent proceſs, by which the acorn becomes an oak, and the embryo becomes a man; by which digeſtion is performed in plants and animals, and, which departing, the body ceaſes to live, and its members putrefy; and by which every being produces another like itſelf, and every ſpecies is continued. In animals, it is that higher faculty, which by employing the organs of ſenſe, peculiar to them as animals, diſtinguiſhes them as ſenſitive beings from vegetables; and it is alſo that more noble faculty, which by its own divine vigour, unaſſiſted perhaps with organs, makes and denominates him a being intellective and rational. So that Mr. Harris reckons two ſorts of *forms*, thoſe which are paſſive elements, and thoſe which are efficient cauſes. And all of them agree in this, that they give to every being its peculiar and diſtinctive character: and on the whole he concludes, that *form* appears in part to be an element, and in part an efficient cauſe, *i. e.* a cauſe which aſſociates the conſtituent elements of natural ſubſtance, and which employs them, when aſſociated, according to their various and peculiar characters. Harris's Phil. Arrangements, chap. vi.

The Philoſophers generally allow two principles of bodies: *matter*, as the common baſis, or ſubſtratum of all; and *form*, as that which ſpecifies and diſtinguiſhes each; and which, added to a quantity of common matter, determines or denominates it this, or that; wood, or fire, or aſhes, &c.

Subſtantial *forms* ſeem to have been firſt broached by the followers of Ariſtotle, who thought matter, under different modes or modifications, not ſufficient to conſtitute different bodies; but that ſomething ſubſtantial was neceſſary to ſet them at a greater diſtance: and thus introduced ſubſtantial *forms*, on the footing of ſouls, which ſpecify and diſtinguiſh animals.

The conſiderations which the Peripatetics principally inſiſt on, in confirmation of this doctrine, are: 1. That, without ſubſtantial *forms*, all natural things would be of the ſame ſpecies, nature, and eſſence; which is ſuppoſed to be an abſurdity.

2. That every thing has its peculiar power, motion, and operation; as the magnet, *e. gr.* has that of attracting iron; but that this power does not flow from the matter of the body, which is only paſſive; nor from the accidents; and therefore that it muſt ariſe from a ſubſtantial *form*.

3. That, without ſubſtantial *forms*, there would be no generation: for a production of accidents is only an alteration.

4. That, without ſuch *form*, the nature of a man and of a lion would not differ.

What contributed much to their error, was the circumſtances of life and death: for obſerving, that, as ſoon as the ſoul was departed out of a man, all motion, reſpiration, nutrition, &c. immediately ceaſed, they concluded that all thoſe functions depended on the ſoul, and conſequently that the ſoul was the *form* of the animal body or that which conſtituted it ſuch: that the ſoul was a ſubſtance, independent of matter, nobody doubted; and hence the *forms* of other bodies were concluded equally ſubſtantial.

But to this it is anſwered, that though the ſoul be that by which a man is man, and conſequently is the *form* of the human body, as human; yet it does not follow, that it is properly the *form* of this body of our's, *as it is* a body; nor of the ſeveral parts thereof, conſidered as diſtinct from each other.

For thoſe ſeveral parts have their proper forms ſo cloſely connected with their matter, that it remains inſeparable therefrom, long after the ſoul has quitted the body: thus fleſh has the *form* of fleſh; bone of bone, &c. long after the ſoul is removed, as well as before.

The truth is, the body does not become incapable of performing its accuſtomed functions, becauſe the ſoul has deſerted it; but the ſoul takes its leave, becauſe the body is not in a condition to perform its functions.

The ancient and modern corpuſcular philoſophers, therefore, with the Carteſians, exclude the notion of ſubſtantial *forms*; and ſhew, by many arguments, that the *form* is only the modus or manner of the body it is inherent in.

And as there are only three primary modes of matter, viz. figure, reſt, and motion, with two others ariſing therefrom, viz. magnitude, and ſituation, the forms of all bodies they hold to conſiſt therein; and ſuppoſe the variations theſe modes are capable of, ſufficient to preſent all the variety obſervable in bodies. See MODE.

Many varieties we actually ſee reſult from changes in theſe modes, which may very well paſs for differences of *form*: thus, an awl only differs from a needle in magnitude; a globe

globe from a cube in figure: and tranſparent glaſs, being pulverized, will reflect the light, and appear white; and yet all the alteration conſiſts in the order and arrangement of the parts: when wheat is ground into flour, all the change conſiſts in a ſeparation of the contiguous parts; and when the flour is baked into bread, what is it but the ſame particles aſſociated again in another manner? By agitating water, a froth is formed: if the agitations be increaſed, the particles will exhale, and form clouds; which being congregated again, return in dew, ſnow, hail, or rain: and the ſame water, by the acceſſion of cold, might have been formed into ice. So many different bodies, endued with different qualities, and which the Peripatetics themſelves allow ſpecifically different, ariſe from one and the ſame body, by mere motion and reſt!

The philoſophy of ſubſtantial *forms*, its riſe, uſe, and extent, are ſet in an excellent light by F. Malebranche.

The way of thinking, that firſt introduced it, is this: every thing I perceive in taſting, ſeeing, and handling this honey and ſalt, is in the honey and ſalt; but it is certain, that the things I perceive in the honey, e. gr. the colour, taſte, &c. differ eſſentially from thoſe I perceive in the ſalt; conſequently there is an eſſential difference between the two.

Hence it follows, that they are groſſly deceived, who take all the differences between thoſe bodies to conſiſt in the different configurations of the component parts; ſince the different figure is not at all eſſential to the different bodies: for, change the figure of the parts of the honey how you will, and even give them thoſe of the parts of ſalt, yet it is honey ſtill.

There muſt, therefore, be ſome ſubſtance added to the common matter of all bodies, to make them eſſentially different. And thus are ſubſtantial *forms* hooked in; thoſe fertile ſubſtances, which perform every thing that we ſee in all nature. Since then, in every natural body, there are two ſubſtances; the one common to honey, ſalt, and all other bodies; and the other, that which makes the honey, honey; the ſalt, ſalt; and all other bodies what they are; it follows that the firſt, viz. matter, having no contrary, but being indifferent to all *forms*, muſt remain without force and action, as having no occaſion to defend itſelf.

But, for the others, viz. the ſubſtantial *forms*, there is a neceſſity of their being accompanied and inveſted with faculties and qualities, for their defence and ſubſiſtence. Theſe muſt be always on their guard, for fear of being ſurpriſed: they are in poſſeſſion of a thing, which they are to hold againſt numerous pretenders; and therefore they muſt be continually at work to fortify themſelves, and extend their dominion over the neighbouring matters, and puſh their conqueſts as far as they can: were they to remain inactive, and unprepared, other *forms* would lay hold of them, and baniſh and deſtroy them for ever. To guard againſt this, they keep conſtant watch, and entertain mortal enmities and antipathies againſt thoſe other *forms*, which only wait to deſtroy them.

If now it happen, that one *form* ſeize the matter or receptacle of another, that the *form* of a carcaſe, for inſtance, ſeize the body of a dog, it is not enough that this new *form* annihilate the former; but its hatred muſt be farther gratified with the deſtruction of all the qualities, that took its enemy's part.

The hair of the carcaſe, then, muſt be turned white, by a creation of a new colour: its blood muſt become red, but of ſuch a red, as not to be ſuſpected in the intereſt of the enemy; and the whole body to be inveſted with qualities, truſty to their new maſter, whom they are to defend with all the power the qualities of a carcaſe can have, till ſuch time as, being overpowered, this *form* gives way too, in its turn, to the *form* of maggots, worms, &c.

But as nothing can be in perpetual war, but every thing has its place of reſt, it follows, that even the fire muſt likewiſe have its centre, whither its natural levity always prompts it, that it may remain at reſt, ceaſe to burn, and even quit its heat, which it only maintains here below for its defence.

Theſe may ſerve as a taſte of the conſequences drawn from that important principle, *ſubſtantial forms*; which is infinitely fertile, and furniſhes every philoſopher with all ſorts of ſolutions, according to his ability, addreſs, inclination, &c.

Forms are uſually diſtinguiſhed into *eſſential* and *accidental*.

FORMS, *Eſſential*. Though the five modes above mentioned, generally taken, be adventitious; yet, to this or that body, e. gr. to fire, or water, they are eſſential: thus, it is *accidental* to iron, to have this or that magnitude, figure, or ſituation, ſince it might exiſt in different ones; yet, to a knife, or hammer, the figure, magnitude, and poſition of parts, which conſtitute it a hammer, or knife, are *eſſential*, and they cannot exiſt, or be conceived, without them.

Hence it is inferred, that, though there be no *ſubſtantial*, there are *eſſential forms*, wherein the ſeveral ſpecies of bodies become what they are, and are diſtinguiſhed from all others.

FORMS, *Accidental*, are thoſe really inherent in bodies, but in ſuch manner as that the body may exiſt in all its perfection without them. Such is whiteneſs in a wall; heat in water; a figure of a man in wax, &c.

FORM, *Metaphyſical*, is nothing elſe but ſpecific difference; as metaphyſical matter is nothing elſe but the genus. Thus, *rational* is the metaphyſical *form* of man.

Form, again, are diſtinguiſhed into *ſimple* and *compound*.

FORMS, *Simple*, are thoſe of ſimple bodies, i. e. of ſuch as have but few properties.

FORMS, *Compound*, are thoſe of more compound bodies; or of ſuch as have more properties.

Thus, e. gr. if the *form* of a hard body be compared with the *form* of wood, the former may be accounted *ſimple*, and the latter *complex*: inaſmuch as a hard body, conſidered only as hard, has fewer properties than wood. Abſolutely ſpeaking, however, *ſimple forms* are thoſe of the elements; and compound, thoſe of mixt bodies.

Some diſtinguiſh *forms* into *natural* and *artificial*.

FORMS, *Natural*, are thoſe inherent in bodies, without any thing contributed thereto on the part of man. Such is the *form* of marble.

FORMS, *Artificial*, are thoſe ariſing from human induſtry. Such is that of a ſtatue. But this diſtinction is uſeleſs, and does not imply any intrinſic difference in the *forms* themſelves.

Others, again, diſtinguiſh *forms* into *primary* and *ſecondary*.

FORMS, *Primary* or *univerſal*, are thoſe which originally belong to phyſical and natural bodies; and theſe, they ſay, are extenſion, figure, and organization; figure having reſpect to its external, organization to its internal, and extenſion being common to both.

FORMS, *Secondary*, are the ſame with ſenſible qualities and ariſe, for the moſt part, from the primary *forms*. Harris's Philoſ. Arrangements, p. 88.

FORM *of concord*, in *Eccleſiaſtical Hiſtory*. See CONCORD.

FORM *of Corporeity*, according to Avicenna, and the Scotiſts, is that which conſtitutes body in the generical eſſe of body.

That there is ſuch a thing, they prove thus: the human body is a natural body, which cannot be placed in the eſſe of body, but by the *form* of corporeity: for it is either ſo placed by this, or by the rational ſoul; not by the ſoul, ſince that is ſpiritual; therefore by the *form* of corporeity. And the ſame may be underſtood of other bodies: but the later philoſophers ſet this aſide as a chimæra.

FORM *of a ſcrue*, in *Agebra*. See SERIES.

FORM, *Syllogiſtic*, is a juſt diſpoſition, both of the terms, in reſpect of predicate and ſubject; and of the propoſitions, in reſpect of quantity and quality.

By juſt diſpoſition, we mean ſuch an one, wherein the concluſion follows duly and legitimately from the two premiſes, there being no *form* where there is no concluſion. See SYLLOGISM.

The diſpoſition of the ſeveral terms, being, as it were, ſo many ſteps or degrees of a *ſyllogiſtic form*, is called the *figure of the ſyllogiſm*.

The diſpoſition of the premiſes alone, being, as it were another degree, is called the *mode of the ſyllogiſm*.

FORM, in *Theology*, denotes one of the eſſential parts of the ſacraments, being that which gives them their ſacramental nature and efficacy.

The *form* conſiſts in certain words, which the prieſt pronounces in adminiſtering them. In ſome of the Romiſh ſacraments, the form is deprecative; in ours it is abſolute, or indicative.

The fathers and ancient divines held, that the ſacraments conſiſted of things and words, *rebus & verbis*. William of Auxerre was the firſt, who, about the beginning of the 13th century, introduced the terms, *matter* and *form*, in lieu thereof.

FORM, is alſo uſed, in a *moral ſenſe*, for a manner of being, or doing a thing according to rules.

This republic has frequently changed its *form* of government; that is, its conſtitution. Pardons generally expreſs a remiſſion or abolition of a crime, in what *form* or manner ſoever it be committed. He was admitted doctor in *forma*. Put your argument in *form*.

FORM, in *Law*, is applied to certain eſtabliſhed rules to be obſerved in proceſſes or judiciary proceedings.

In which ſenſe the word ſtands oppoſed to the ground or matter in diſpute, or the merits of a cauſe.

Contra FORMAM *collationis, feoffamenti*, and *ſtatuti*. See CONTRA.

Mode

Mode & FORMA. See MODE.

FORM, in *Joinery*, &c. is applied to the long seats or benches in the choir of churches, for the priests, canons, prebendaries, religious, &c. to sit on.

Du-Cange takes the name to be derived from hence, that the backs of the seats were anciently enriched with figures of painting and sculpture, called in Latin *formæ & typi*. In the life of St. William of Rochfild, we meet with *forma* as signifying a seat for an ecclesiastic, or religious, in a choir; and in that of St. Lapicin, we have *formula* in the same sense. In the rule of the monastery of St. Cæsarea, the man who presides over the choir is called *primicerius, vel formare*.

FORM is also used in the same sense with CLASS.

FORM also denotes the external appearance or surface of a body; or the disposition of its parts, as to length, breadth, and thickness.

In which sense it coincides with figure.

FORM is also used, in the *Mechanic Arts*, for a kind of mould whereon a thing is fashioned or wrought.

Such are the batters *form*, the paper-makers *form*, &c.

FORM, *Hatters*, is a large block or piece of wood of a cylindrical figure; the top whereof being rounded, and the bottom quite flat.

Its use is, to mould or fashion the crown of the hat, after the matter thereof has been beaten and fulled.

To *form* a hat, it is necessary the wool, hair, &c. be very hot, just reeking out of the copper.

FORM, *Paper-makers*, is the frame or mould wherein the sheets are fashioned. See PAPER.

FORM, *Printers*, is an assemblage of letters, words, and lines, arranged in order, and disposed, into pages, by the compositor; from which, by means of ink and a press, the printed sheets are drawn.

Every *form* is inclosed in an iron chase, wherein it is firmly locked by a number of pieces of wood, some long and narrow, and others in *form* of wedges.

There are two *forms* requisite for every sheet; one for each side: and each *form* consists of more or fewer pages, according to the volume of the book. See PAGE, and IMPOSING.

FORM, in *Hunting*, denotes the seat of a hare; or the place and time when and where she squats.

FORMA *Pauperis*, or *in* FORMA *Pauperis*, is when any person has a cause of suit, but is so poor that he cannot dispend the usual charges of suing at law, or in equity.

In this case, upon his making oath that he is not worth 5*l.* his debts being paid, and bringing his certificate from some lawyer, that he has just cause of suit, the judge admits him to sue in *forma pauperis*; that is, without paying fees to the counsellor, attorney, or clerk. This custom has its beginning from stat. 11 Hen. VII. cap. 12. See DISPAUPER.

FORMAL, something that regards the *form*; or that gives the manner, or *form*.

The *formal* cause, joining itself to the material, produces the body, or compound.

The schoolmen also apply the word to any thing which has a kind of *form*, either essential or accidental, at least, in our conception.

Thus we frequently hear the philosophers talk of the *formal* object of knowledge; and of the formal reason of any thing; *formal* unity, &c.

FORMAL *cause* is defined, by certain philosophers, to be something implanted in one parcel of matter, whereby it is distinguished from all other matter.

For matter is supposed common to all bodies: consequently, that they are distinguishable from one another, does not arise from their matter, but from the *form* which is peculiar to each: hence, what is produced by such cause, is said to be *formal*.

Hence it follows, that the causality of matter and *form* is not the same; or that the component power and the actual composition, are different; contrary to the opinion of the generality of schoolmen, who, maintaining *form* to be a substance co-extended with matter, make it a real component part, as much as matter itself.

FORMAL *circle*. See CIRCLE.

FORMAL *notion*. See NOTION.

FORMAL is also used in a moral sense, importing positive, express, and precise.

Thus we say, a *formal* agreement, a *formal* text, *formal* answer, &c. *Formal* evidence. See EVIDENCE.

FORMALITER, FORMALLY, is variously used in the schools.

Sometimes it is understood of the subject, when a predicate is therein on account of some form: thus, white, *formally* taken, diffuses light; q. d. the form inherent in this subject, viz. whiteness, is the cause why the subject disperses the light.

FORMALLY has also place in suppositions: a word being *formally* supposed, when it is taken for the thing it was intended to signify: as, *man is an animal*.

FORMALLY, is also used in the same sense with *adequately*, and totally: thus, a syllogism *formally*, i. e. adequately taken, requires three propositions.

Sometimes it is also used for *qualitatively*: thus man, *formally* taken, is a reasonable animal.

FORMALLY is also used for *really*, in opposition to objectively; thus, a thing is said to be *formally* such, when it is such in the proper notion of the thing spoken of.

FORMALLY, again, is used in speaking of the manner wherein a thing is contained in another, in opposition to VIRTUALLY, and EMINENTLY.

FORMALITY, the quality of a *form*, or *formula*; or that which constitutes and denominates them such.

FORMALITY, as defined in the *schools*, is any manner, wherein a thing is conceived; or, a manner to any object, importing a relation to the understanding, whereby it may be distinguished from another object.

Thus, animality and rationality are *formalities*. The Scotists make great use of *formalities*, in opposition to the virtualities of the Thomists.

The Scotists hold, that the metaphysical degrees in man are so many *formalities*, really distinct from each other; as *man, living, animal*, &c. And the same they hold of the attributes of God. The Thomists, on the contrary, contend, that they are really and intrinsically the same.

FORMALITIES, in *Matters of Law*, are frequently used for the formulas themselves, or the rules prescribed for judiciary proceedings. In contracts of that law, all the *formalities* must be strictly observed: no omission of the least *formality* may stain the whole convention.

The term is also used for a certain order, or decorum, to be observed.

FORMATION, in *Philosophy*, &c. the act of forming, fashioning, or producing, a thing.

The *formation* of the chick in the egg is admirably explained by Malpighi, in an express treatise, *De Formatione Pulli in Ovo*.

The *formation* of the FOETUS, the embryo, in the womb, is a process of which we have but very dark conceptions. See GENERATION.

The *formation* of metals is effected in the earth, of fumes, or vapours raised by the subterraneous fire, and fixed or condensed as they arrive towards the surface of the earth.

FORMATION *of stones*. See STONES.

FORMATION *of pebbles & gems*. See CRYSTAL.

FORMATRIX, or FORMATRICE. The ancient philosophers admitted a *virtue*, or *faculty formatrice*, whereby all bodies had their forms given them.

FORMATUM *punctum*. See PUNCTUM.

FORME', or FORMY, in *Heraldry*. A *cross* FORMY, or *formy*, is a cross narrow in the centre, and broad at the extremes; so called by Leigh and Morgan, though most other authors call it *patée*.

FORMED, or FIGURED *Agate*, among *Naturalists*, are such bodies, as, being either pure stone, flint, or spar, are found in the earth, *so formed*, as that they bear a near resemblance to the external figure of muscles, cockles, oysters, or other shells, or to plants, or animals.

Authors have been greatly divided as to their origin: the several opinions see under the articles, FOSSIL, SHELL, &c.

FORMED *bachelor*. See BACHELOR.

FORMED, in *Heraldry*, the same as *fretted*.

FORMEDON, *formedon formam dari*, in *Law*, a writ which lies for him who has right to lands or tenements by virtue of an entail arising from the statute of Westm. 2. 13 Edw. I. cap. 1.

The time of limitation in a *formedon*, by stat. 21 Jac. I. cap. 16. is twenty years; within which space of time, after his title accrues, the demandant must bring his action, or else is for ever barred.

There are three kinds, viz. *forma donationis*, or *formedon in the descender*; *formedon in the remainder*; and *formedon in the reverter*.

FORMEDON *in the descender* lies for the recovery of lands, &c. given to one and the heirs of his body; or to a man and his wife, and the heirs of their two bodies; or to a man and his wife, being cousin to the donor, in frank marriage, and afterwards alienated by the donee.

After his decease, his heir shall have this writ against the tenant or alience.

Fitz. Nat. Br. *fol.* 211, &c. makes three sorts of *formedon* in the descender: the first is that now expressed; the second, for the heir of a coparcener that aliens, and dies; the third he calls *infinual tenure*, which lies for a coparcener, or heir in gavel-kind, before partition, against him to whom the other coparcener or heir has alienated, and is dead.

FORMEDON *in the remainder* lies, where a man gives land to another for life or in tail, with the remainder to a third person in tail or in fee; and afterwards the former

tenant dies without iſſue, and a ſtranger abates; then he in remainder ſhall have this writ.

FORMEDON *in the reverter*, lies for the donor, or his heirs (whoſe land is intailed to certain perſons, and their iſſue, with condition, for want of ſuch iſſue, to revert to the donor, and his heirs), againſt him to whom the donee alienates after the iſſue extinct to which it was intailed.

FORMELLA, a certain weight of about ſeventy pounds, mentioned in the ſtatute of weights and meaſures, 51 Hen. III.

FORMER, in *Gunnery*, a round piece of wood fitted to the diameter of the bore of a gun, on which the paper, parchment, or ſtuff, which is to make the cartridge, is rowled before it be paſted or ſewed.

FORMICA, in *Zoology*. See ANT.

FORMICA, in *Medicine*, a ſpecies of tumid callous wart, of a blackiſh colour, and broad baſe, which appears like the ſtingings of ants; called alſo *myrmecia*.

And hence the name *formica*, which literally denotes an ant: for the like reaſon it is denominated by the Greeks, μυρμηξ.

The name *ant*, *formica*, is alſo given to thoſe minute varicous intumeſcences of the ſmalleſt blood-veſſels, obſerved either in the anus, or the glans of the penis.

Some alſo give the appellation ant, or *formica*, to the miliary herpes.

FORMICA, among *Sportſmen*, the name of a diſeaſe incident to ſpaniels. See SPANIEL.

FORMICA-*leo*, the *ant-lion*, in *Natural Hiſtory*, the name given by authors to a very remarkable ſpecies of inſect, which is, in its perfect ſtate, a winged creature, approaching to the nature of the *libella*, or DRAGON-*fly*; but in its prior ſtate of a creeping animal, has a wonderful art and addreſs in catching its prey. It is in this ſtate that it is known by the name of *formica-leo*, as it chiefly feeds upon ants.

It is ſomewhat of the nature of the ſpider in its way of taking its prey, its manner of ſpinning, and in the figure and faſtneſs of its body, and has, to its general figure, ſomewhat of the appearance of the millepes, or woodlouſe; ſo that ſome have miſtaken it at firſt ſight for that animal. It is of a dirty greyiſh colour marked with ſome black ſpots, and there are alſo many points, which when it is viewed with the microſcope, make it reſemble a hedge-hog or porcupine. Its body is compoſed of ſeveral rings, and has thence a wrinkled look. It has ſix legs; four are joined to the breaſt, and the other two to a long part which may be taken for its neck; its head is ſmall and flat, and it has two remarkable horns; theſe are about a ſixth of an inch long, and as thick as a hair, and are hard, hollow, and hooked at the end, like the claws of a cat; at the origin of each of theſe horns, it has a clear and bright black eye, which ſees very diſtinctly, and gives the creature notice to eſcape on ſight of the ſmalleſt object. Mem. Acad. Par. 1704.

He uſually encamps under an old wall, that he may be ſheltered from the injuries of the weather, and he always chuſes a place where the ſoil is compoſed of a fine dry ſand; in this he makes a pit of the ſhape of a funnel, or an inverted hollow cone.

When he has finiſhed his pit, he buries himſelf at the bottom of it in the ſand, leaving no part above ground, but the tips of his two horns, which he expands to the two ſides of the pit. In this condition he lies and waits for his prey, and never comes up after it. When an ant, or any other ſuch creature, chances to walk over the edges of his pit, his ſteps throw down a little of the ſand, which naturally running down to the bottom of the pit, gives the enemy notice of his prey; he then toſſes up the ſand which covers his head, to bury the ant, and bring him down with its returning force to the bottom; and as one attempt cannot be ſufficient to prevent the ant's eſcape, he throws more and more ſand upon him, till he by degrees brings him down to the bottom. All the endeavours of the ant to eſcape, when once it is within the verge of the pit, are in vain; for, as it attempts to climb, the ſand runs away from under its feet, and it ſinks the lower for every attempt. This motion of the ſand alſo informs the enemy where it is, and directs him to throw up more ſand in the right place, which it does till the poor ant falls to the bottom between its horns. It then plunges their points deep into the ant's body, and having ſucked out all the juices of the prey, it throws out the empty ſkin, as far from the hole as it can. This done, it mounts up the edges of its pit, and if they have ſuffered any injury, repairs them with great care, and immediately buries itſelf again in the centre to wait for another meal.

The horns of this creature are its only organs for receiving nouriſhment; it never brings any animal that it has ſeized near to its head, but always holds it at the tip of the horn: they therefore plainly ſerve as ſyringes, to draw into its ſtomach the juices of the bodies of the inſects it feeds on: neither is there any mouth or trunk, or any other organ to be diſcovered about its head, which could ſerve to the purpoſe of eating, the head ſeeming only intended to throw away the ſand in forming the pit. The horns of this animal being ſo neceſſary to its life, nature has provided for the reſtoring them in caſe of accidents, and if cut off they are found to grow again.

When the *formica-leo* has lived a proper time in this ſtate, it leaves its pit, and is only ſeen drawing lines and traces on the ſurface of the ſand; after this it buries itſelf under the ſurface, and there incloſes itſelf in a fine web to paſs its tranſformation into the winged ſtate. This caſe is made of a ſort of ſilk, which the creature ſpins in the manner of the ſpider, and of a quantity of the grains of ſand cemented together by a glutinous humour which flows from its pores. This caſe, however, would be too harſh and coarſe for the body of the creature, and therefore it ſerves only for the outer covering, to defend it from injuries; the creature ſpinning one of pure and incomparably fine ſilk, of a beautiful pearl-colour within it, which covers its whole body.

When the creature has lain ſome time in this caſe, it throws off its outer ſkin, with the eyes, the horns, and every other part neceſſary to its life before, and becomes an oblong nymph, in which a careful eye may trace the form of the fly it is to become. There may be ſeen through its tranſparent covering, new eyes, new horns, wings, and all the other parts of the animal in its perfect ſtate. This nymph makes it way about half out of the ſhell, and remains in this condition, but without farther life or motion, till the perfect fly makes its way out at a ſlit in the back, in this ſtate it much reſembles the libellæ or dragon-flies common about our waters. The male couples with the female in this ſtate only, and Mr. Poupart, to whom the world is indebted for this curious deſcription, is of opinion that the females lay only one egg; but this is very different from the courſe of nature, in the other animals of the ſame claſs. Mem. Acad. Par. 1704.

The common *formica-leo* moves only backward, but Mr. Rouet has obſerved a ſpecies which moves forward in the common way of other animals, and makes no pit of this kind to intrap its prey, but ſeizes other inſects by force. Philoſ. Trans. N° 469. p. 466.

FORMICATION, a term uſed among *Builders*, for arching or vaulting.

FORMING is uſed for the act of giving being or birth to any thing.

The word is alſo ſimply uſed for giving the figure to any thing. The potter *forms* his veſſels as he pleaſes. Geometry teaches how to *form* all kinds of figures.

It is alſo uſed for the producing of a thing: thus, the lineaments of the face began to be *formed*.

FORMING *of a ſiege* is the making lines of circumvallation, to fortify the camp, and diſpoſing things for the attack of a place in *form*.

They alſo ſay, to *form* a ſquadron or battalion; meaning, to range the ſoldiers in *form* of a ſquadron, &c.

The term is alſo uſed in ſpeaking of a body of forces, which being out of any order of ſquadrons, battalions, &c. do halt, range themſelves in order, and put themſelves in a condition for the attack.

Forming the line, is drawing up infantry, cavalry, and artillery, into line of battle. See LINE.

Angle FORMING *the ſame*. See ANGLE.

FORMING is alſo uſed in grammar, in ſpeaking of certain tenſes of verbs, which are made from others, by a change of certain letters.

The preſent tenſe is *formed* from the infinitive. Compound and derivative words alſo, and even all that have any etymology, are ſaid to be *formed*.

FORMULA, a rule, or model, or certain terms preſcribed and decreed by authority, for the form and manner of an act, inſtrument, proceeding, or the like.

The Roman law was full of *Formulæ*. The *Formulæ* of Marculphus, with M. Bignon's Comment, are in great eſteem.

FORMULA, in *Church-hiſtory* and *Theology*, denotes a formulary or profeſſion of faith.

FORMULA, in *Medicine*, denotes a little form, or preſcription, ſuch as phyſicians direct in extemporaneous practice, in diſtinction from the greater forms, which are the official medicines. See PRESCRIPTION.

FORMULARY, a writing, containing the form or formula of an oath, declaration, atteſtation, or abjuration, &c. to be made on certain occaſions.

There are alſo *formularies* of devotion, of prayers, &c. Liturgies are *formularies* of the public ſervice in moſt churches.

FORNA, in *Ichthyology*, a name given by Hildegard, and others, to the trout.

FORNACALIA, or FORNICALIA, a feaſt held among the ancient Romans, in honour of the goddeſs Fornax, or Fornix. It was ſolemnized with ſacrifices, performed

before the mouth of an oven, wherein they dried their corn, baked their bread, &c. The *fornicalia* were moveable: the grand curio proclaimed the time of celebration every year on the twelfth of the calends of March. They were firſt inſtituted by Numa: and the QUIRINALIA were inſtituted for the ſake of ſuch as had not kept the *Fornicalia*.

FORNAGE, *fornagium*, in *our Old Writers*, ſignifies the fee taken by a lord from his tenants, bound to bake in the lord's oven, or for a permiſſion to uſe their own; this was uſual in the northern parts of England.

The word comes from the French *fournage* which ſignifies the ſame.

FORNICATION, *fornicatio*, the act or crime of incontinency between ſingle perſons; for, if either of the parties be married, it becomes adultery.

St. Thomas labours much to prove ſimple *fornication* contrary to the law of nature.

By the ancient law of England, the firſt offence herein was puniſhed with three months impriſonment: the ſecond was made felony, by an act in the time of the late uſurpation. At preſent, doing public penance is the chief puniſhment. See BASTARD.

FORNICATION is ſometimes uſed as a generical term, including all kinds of offences againſt chaſtity.

Its ſpecies are, 1. *Simple fornication*, which is that committed with a proſtitute. 2. *Sacrum*, that committed with perſons of reputation and ſobriety. 3. That committed with relations, called *inceſt*. 4. That committed with married perſons, *adultery*. 5. That committed with perſons conſecrated to God, *ſacrilege*. 6. That committed between perſons of the ſame ſex, *ſodomy*. 7. That committed by perſons on themſelves, *manuſtupration*. And, 8. That committed with beaſts, *beſtiality*.

FORNIX, in *Anatomy*, the extremity of the corpus calloſum, next the cerebellum; which is ſeparated or diverſicated into two legs, forming a kind of arch, or *fornix*. See CORPUS *callojum*.

FORPRISE, in *Law*, an exception, or reſervation: in which ſenſe the word is uſed in the ſtatute of Exon. 14 Edw I.

We ſtill uſe it in conveyances and leaſes, wherein excepted and *forpriſed* are ſynonymous terms.

FORPRISE is alſo uſed for an exaction: in which ſenſe it amounts to the ſame with forceapium.

Tenuit pratum &c. ſine quacunque forpriſa in excambium pro ſpinea dicit.

FORRAGE, or FORAGE, proviſion for cattle, of hay, oats, and ſtraw; particularly in war.

Skinner derives the word from *foras agere*, by reaſon they go abroad to ſeek *forrage*: others from *for*, which anciently ſignified any kind of corn or grain. Menage, from *fodarogium*, of *fodrum*, or *fodrum*, which the Romans uſed in the ſame ſenſe. Cujas and Du-Cange derive it from the German *futter*, *horſe-meat*; Voſſius, from the German *fuden*, or *voeden*, *to feed*; Nicod, from *forrage*, which literally ſignifies what we call *forrage*, and figuratively, mixture of divers kinds of things; Hicks derives it from the Saxon *fodra*, or the Engliſh *fodder*, or the baſe Latin *fodrum*. See FODDER.

In marching, encamping, &c. care muſt be taken, that the cavalry may find *forrage*.

A ration of *forrage* is the portion of hay, ſtraw, and oats, allowed each horſeman, for the ſubſiſtence of his horſe one day; which is twenty pounds of hay, five of ſtraw, and ten pounds of oats. See RATION.

FORRAGE-*guard*, in *Military Affairs*, a detachment ſent out to ſecure the *forragers*. The *forrage* guard is poſted at all places, where the enemies parties may come to diſturb the *forragers*. This guard is likewiſe called the *covering party*, and marches generally the night before the *foraging*, that they may be poſted in the morning before the *forragers* come. The guard conſiſts both of horſe and foot, and muſt ſtay at their poſt till the *forragers* be all come off the ground.

FORSES, *cataractæ*, a term uſed in Weſtmoreland for water-falls.

FORSKHOLEA, in *Botany*, a genus of the *decandria pentagynia* claſs, with a five-leaved calyx extending beyond the corolla, ten ſpatulated petals, no pericarpium, and five ſeeds connected by a woolly down. There is one ſpecies.

FORSTAL. } See { FORESTAL.
FORSTALLING. } See { FORESTALLING.

FORT, a little caſtle or ſotterſs; or a place of ſmall extent, fortified by art, or nature, or both.

A *fort* is a work encompaſſed round with a moat, rampart, and parapet, to ſecure ſome high ground, or paſſage of a river; to make good an advantageous poſt; to fortify the lines and quarters of a ſiege.

FORT, *field*, otherwiſe called *Fortin* or *Fortlet*, and ſometimes *Scanſe*, is a ſmall *fort*, built in haſte, for the defence of a paſs or poſt; but particularly conſtructed for the defence of a camp in the time of a ſiege, where the principal quarters are uſually joined, or made to communicate with each other, by lines defended by curtins and redoubts. Their figure and ſize are various, according to the nature of the ſituation, and the importance of the ſervice for which they are intended. Some are fortified with baſtions, and ſome with demi-baſtions. A *fort* differs from a CITADEL, as this laſt is erected to command and guard ſome town; and from a redoubt, as it is cloſed on all ſides; whereas a redoubt is open on one ſide. *Forts* are moſt commonly made ſquare (ſee *Tab. Fortification, fig.* 5.) eſpecially when the paſs they are to guard is of any conſequence, or the place may eaſily be approached: the ſides of this ſquare are a hundred toiſes, the perpendicular ten, and the faces twenty-five; the ditch about this *fort* may be from ten to twelve toiſes; the parapet is to be made of turf, and fraiſed, and the ditch paliſſadoed when dry. There may be made a covert-way about this *fort*, or elſe a row of paliſades might be placed on the outſide of the ditch. A *ſquare fort* may be fortified in the following manner: having inſcribed the ſquare in a circle, divide each of its ſides, A B, B D, &c. into two equal parts in the points F, M, &c. from the centre E draw an indefinite line E F, from the centre draw alſo the lines E A, E B, E D, E C, to the angles of the ſquare; divide the ſide A B into eight equal parts, and ſet off one of theſe parts from F to G, and from G draw the lines of defence A C, B G; divide another ſide of the ſquare into ſeven equal parts, and ſet off two of thoſe parts from A to K, and from B to L, which will be the faces of the baſtions, take the diſtance K I, in your compaſſes, and ſet it off on the lines of defence from K to H, and from L to I, and draw H I, which will be the curtain, and the lines K I, L H, will be the flanks. Or, it may be otherwiſe fortified thus: let the ſide A A (*fig.* 6.) be a hundred and thirty fathoms; the demi-gorge A B, twenty five fathoms; and with the compaſſes opened to the length of the pinched line B C B, which is the diagonal of two ſides, from each of which there has been taken twenty-five fathoms, upon the extremity oppoſed to the angle which they form, deſcribe two arcs above the angle of the figure, alternately making uſe of the points B for centres; then draw lines from the points of interſection of the arcs D, to the point which ſerved for centres B, upon which points B, raiſe the flanks B E perpendicular to the oppoſed lines of defence B D.

FORT *pain, & dure*. See PAINE.

FORT *royal* is a *fort*, whoſe line of defence is at leaſt twenty-ſix fathoms long.

FORT, *ſtar*, is a ſconce or redoubt, conſtituted by re-entering and ſaliant angles, having commonly from five to eight points, and the ſides flanking each other.

To deſcribe a ſtar-fort. Deſcribe a hexagon *a B C d e f*: (*fig.* 7.) divide one of its ſides into four equal parts; and on the centre of this ſide raiſe the perpendicular D A equal to one fourth of the ſide B C. From the point A draw the faces A C and A B, and let the ſame operations be performed with reſpect to the other ſides of the hexagon.

FORTS are ſometimes made *triangular*, only with half baſtions, as in *fig.* 8. This, as well as the ſquare and pentagonal *forts*, (*fig.* 9. and 10.) may be deſcribed in the following manner. Parallel to the inner figure, whether it be a triangle, ſquare, or pentagon, whoſe ſide A B may be ſuppoſed about eighteen yards, deſcribe an outward figure at the diſtance of about four or five yards from it, or farther, if neceſſary, whoſe ſides are E D, E F, &c. Divide each ſide, as E D, E F, &c. into three equal parts, one of which is E I, F L, &c. and in theſe ſides prolonged, take D G, E H, &c. each equal to one of theſe three parts. From the points G, H, &c. thus found, draw the lines of defence to the angles of the outward figure, as H D, &c. and from the points I, L, &c. draw the flanks I K, L M, &c. perpendicular to the lines E D, E F, meeting the lines of defence in K, M, &c. Or the flanks may be drawn, by continuing the ſide D E towards E, and taking I P equal to twice I E; from P as a centre, with the radius P I, cut the line of defence in K, and draw the flank I K. Then to each face H K, flank K I, and curtin I G, make a parapet of about ſeven feet thick, or more if neceſſary, expreſſed in the figures, by drawing lines at that diſtance on the inſide of the ſeveral parts. Leave a proper berm of about four or five feet broad, and make a ditch about five or ſix yards wide, whoſe outer line or counterſcarp is to be parallel to the faces and curtins only. A *fort* thus conſtructed is more capable of defence than one without flanks; for the curtin I G is defended by the flank I K, and the face H K has ſome defence from the part D G. In the conſtruction of triangular *forts*, (*fig.* 11.) inſtead of making half baſtions at the angles, whole ones are placed in the middle of the ſides. The gorges of theſe baſtions may be from twenty to twenty-four toiſes, when the

the sides are from a hundred to a hundred and twenty; the flanks are perpendicular to the sides, from ten to twelve toises long, and the capitals from twenty to twenty-four. If the sides happen to be greater or less, the parts of the bastions are likewise made greater or less in proportion: the ditch round this *fort* may be ten or twelve toises wide. The ramparts and parapets of these works are commonly made of turf, and the outside of the parapet fraised. *Forts* are often made of various figures, regular or irregular, and sometimes in the form of a semi-circle, especially when they are situated near a river, sea, or at the entrance of a harbour, by which figure they are able to fire at the ships on all sides. When a *fort* is to be built on a neck of land, formed by the confluence of two rivers, or in the windings of a river, in order to prevent an enemy from transporting any thing by water, or to prevent their ships passing that way, the figure of the *fort* must be adapted to the situation, in such a manner, that there may be no place for landing troops out of the reach of the fire of some work or other; and the side next to the land should always be better fortified than the other parts near the river, as being more liable to an attack. There are two principal errors committed in the construction of *forts* near the sea, or navigable rivers, which should be carefully guarded against; the one is, that of making the parapet too low, so that persons behind it may be fired upon from the round top of a mast, by which the gunners are obliged to abandon their guns, and to save themselves by flight: to remedy this inconvenience, the parapet should be nine or ten feet high, and the batteries may be covered above by making an arch over every piece left open behind to let out the smoak, or with planks, like sheds, over which may be scattered earth or dung about a foot and half thick, to prevent the wood from taking fire.

The other fault is, leaving *forts* or batteries open behind, or very little fortified towards the land, so that the enemy may land men in the dark and surprise them, by which the guns placed in them become not only useless, but serve rather to destroy them. A *fort*, or battery, therefore, should be fortified all round with a good rampart and ditch, at least, or with an addition of outworks, if the place is of any importance: the rampart should be fraised, and the ditch have a row of palisades planted in the middle of it, if it be dry. In the construction of all *forts*, it should be remembered, that the figure of fewest sides and bastions, that can probably answer the proposed defence, is always to be preferred; as works on such a plan are sooner executed, and with less expence; besides, fewer troops will serve, and they are more readily brought together in case of necessity.

FORTAMENTE, in the *Italian Musick*, the same with FORTE.

FORTE, in the *Italian Musick*, directs to play strong and loud.

FORTE FORTE, or F. F. signifies a degree louder or stronger than *forte*.

FORTE, *pia*, the same as *forte forte*.

FORTERESSE, FORTRESS, or FORTRESS, a general name for all FORTIFIED *places*, whether made by nature or art. Such are fortified towns, castles, citadels, forts, towers redoubts, sconces, &c.

FORTIFICATION, called also *military architecture*, is the art of *fortifying* or strengthening a place, by making works around the same, to render it capable of being defended by a small force, against the attacks of a more numerous enemy.

Some authors go back to the beginning of the world, for the author and origin of military architecture. According to them, God himself was the first engineer; and Paradise, or the garden of Eden, was the first fortress. Cain improved on the hint, in building the first city, Gen. iv. 17. After him came Nimrod, Gen. x. 10. Then Semiramis, as Polianus relates. Stratagem. lib. viii. cap. 27. The Canaanites, Numb. xiii. 29. Deut. i. 28. David, 2 Sam. v. 9. Solomon, 2 Chron. viii. 4. Rehoboam his son, 2 Chron. xi. 5. and the other kings of Judah and Israel; and at length the Greeks and Romans. Vitruvius, lib. 2. cap. ult. and lib. i. cap. 5.

Such is the series of those who *fortified* places; to which might be added Pharaoh, the persecutor of the Israelites, who built the cities of Pithom and Raamses, Exod. i. 11. The progress of *fortification*, founded first in necessity, has been, like that of other important and useful arts, gradual. When villages and towns were first formed, it was found necessary, for the common safety, to encompass them with walls and ditches, in order to prevent all violence and sudden surprizes from their neighbours: when offensive weapons were invented, walls were made with loop-holes at proper distances, in order to screen the defenders against the arrows of the assailants; but finding, that as soon as the enemy got close to the walls, they could from no part be discovered or repulsed, they added square towers at proper distances from each other, so that every part of the wall might be defended by the adjacent side of the towers. However, this manner of inclosing towns was found to be imperfect, because there remained still one of the faces of the towers which fronted the field, that could not be seen from any other part, and, therefore, could not be defended. To remedy this, they made the towers round instead of square, imagining this figure to be the strongest for resisting the battering engines, and likewise to be better defended from the other parts of the wall. Nevertheless, part of these towers remained unseen, and incapable of being defended, which made them change them again into squares as before; but, instead of presenting a face to the field as formerly, they presented an angle; and thus they obtained such a disposition of their works, that no part could be attacked without being seen or defended by some other part.

But how ancient soever the furrounding of cities with walls, towers &c. may be, the name *fortification*, and the art now underſtood thereby, are of no very old ſtanding.

Theſe have had their riſe ſince the invention of cannons; the terrible effects whereof rendered it neceſſary to change the ſtructure of the ancient walls, and to add ſo many things thereto, that thoſe changes were thought enough to conſtitute a new art, which was called *fortification*, on account of the ſtrength it afforded thoſe cities, to defend them againſt an enemy.

The period, in which the modern practice of military architecture may be ſuppoſed to have taken its riſe, was that in which the old irregular towers were firſt converted into BASTIONS, about the year 1500.

The firſt authors who have written of *fortification*, conſidered as a particular formed art, are La Treilie, Alghiſi, Marchi, Paſino, Rameili, Cataneo, and Speckle, who, as Mr. Robins ſays, was one of the greateſt geniuſes that has applied to this art. He was architect of the city of Straſburgh, and died in the year 1589. He publiſhed a treatiſe of *fortification* in German, which was reprinted at Leipſic in 1736. Robins's Math. Tracts, vol. i. preface, p. 9.

After them Errard, engineer to Henry the Great of France; Stevinus, engineer to the prince of Orange; Marolois, the chevalier de Ville, Lorini, Cochorn, the count de Pagan, and the marſhal de Vauban; which laſt two noble authors have contributed greatly to the perfection of the art. To whom we may add Scheiter, Mallet, Belidor, Blondel, Muller, &c.

From the idea and office of *fortification*, ſome general fundamental rules or axioms may be drawn; as,

1. That the manner of *fortifying* ſhould be accommodated to that of attacking; ſo that no one manner can be aſſured always to hold, unleſs it be aſſured the manner of beſieging be incapable of being altered; and that to judge of the perfection of a *fortification*, the method of beſieging at the time when it was built muſt be conſidered.

2. All the parts of a *fortification* ſhould be able to reſiſt the moſt forcible machines uſed in beſieging, and they ſhould be equally ſtrong on all ſides.

3. A *fortification* ſhould be ſo contrived, as that it may be defended with as few men as poſſible; which conſideration, when well attended to, ſaves a vaſt deal of expence.

4. That the defendants may be in the better condition, they muſt not be expoſed to the enemy's guns and mortars; but the aggreſſors muſt be expoſed to theirs.

Hence, 5. All the parts of a *fortification* ſhould be ſo diſpoſed, as that they may defend each other: in order to this, every part there is to be flanked, i. e. capable of being ſeen and defended from ſome other; ſo that there be no place where an enemy can lodge himſelf, either unſeen, or under ſhelter.

6. All the champaign around muſt lie open to the defendants; ſo that no hills or eminence muſt be allowed, behind which the enemy might ſhelter himſelf from the guns of the *fortification*; or from which he might annoy them with his own.

The forteſs, then, is to command all the place round about; conſequently the out-works muſt all be lower than the body of the place.

7. No line of defence is to be above point-blank muſquetſhot, which is from one hundred and twenty to one hundred and fifty fathom.

8. The acuter the angle at the centre, the ſtronger is the place; as conſiſting of the more ſides, and conſequently more defenſible.

9. All the defences ſhould be as nearly direct as poſſible. Such are the general laws and views of *fortification*; the particular ones, reſpecting each ſeveral work or member thereof, will be delivered under their proper articles. See BASTION, and FORTIFIED *place*.

FORTIFICATION, *the art of*, may be diſtinguiſhed into two parts, viz the *elementary* or *theoretical*, and *practical*.

FORTI-

FORTIFICATION, *elementary* or *theoretical*, conſiſts in tracing the plans and profiles of a *fortification* on paper, with ſcales and compaſſes; and in examining the ſyſtems propoſed by different authors, in order to diſcover their advantages and diſadvantages.

FORTIFICATION, *practical*, conſiſts in forming a project of a *fortification* according to the nature of the ground, and other neceſſary circumſtances, tracing it on the ground, and executing the project, together with all the military buildings, ſuch as magazines, ſtore-houſes, bridges, &c.

FORTIFICATION again is either *offenſive* or *defenſive*. *Offenſive fortification* is the ſame with the ATTACK of a place, and is the art of making and conducting all the different works in a SIEGE, in order to gain poſſeſſion of the place.

FORTIFICATION, *defenſive*, or DEFENCE, is the art of defending a town that is beſieged, with all the advantages which the *fortification* of it will admit.

FORTIFICATION is alſo uſed for the place *fortified*; or the ſeveral works raiſed to defend and flank it, and keep off the enemy.

All *fortifications* conſiſt of lines and angles, which have various names, according to their various offices.

The principal angles are thoſe of the *centre*, the *flanking* angle, *flanked* angle, angle of the *epaule*, &c.

The principal lines are thoſe of *circumvallation*, of *contravallation*, of the capital, &c. See each in its place.

Fortifications are divided into *regular*, and *irregular*, and again into *durable* and *temporary*.

FORTIFICATION, *regular*, is that wherein the baſtions are all equal; or that which is built in a regular polygon, the ſides and angles whereof are generally about a muſquet-ſhot from each other.

In a regular *fortification*, the parts being all equal, have the advantage of being equally defenſible; ſo that there are no weak places.

FORTIFICATION, *irregular*, is that wherein the baſtions are unequal, and unlike; or the ſides and angles not all equal, and equidiſtant.

In an irregular *fortification*, the defence and ſtrength being unequal, there is a neceſſity for reducing the irregular figure, as near as may be, to a regular one; i. e. inſtead of inſcribing it in a circle, it ſhould be inſcribed in an oval, ſo that one half may be ſimilar and equal to the other half.

And as the irregularity of a figure depends on the quantity of angles and ſides; the irregularity of a *fortification* ariſes either from the angles being too ſmall, or the ſides being too long, or too ſhort.

Conſequently an irregular figure being propoſed to be fortified; all the angles, with the quantity of the ſides, muſt be found, to be able to judge how it is to be fortified. See *Tab.* VI. *Fortification, fig.* 36. which repreſents a *fortification* inſcribed in an oval.

In this caſe the ſides CD, GH, on the flat parts, are ſtronger than the ſides AB, EF, on the narrow parts, ſuppoſing all the exterior ſides equal, and the place equally fortified. When the angles BCD, CDE of the polygon are very great, and the beſieger comes within a ſmall diſtance of the works, he cannot approach nearer, without being ſeen in front, except by a direct ſap, with traverſes; and as this way of approaching preſents but a ſmall front, the beſieged, who have a much larger, may oppoſe with peculiar advantage: whereas, if the angles HAB, ABC of the polygon, are very ſmall, the beſiegers may carry their approaches to the counterſcarp itſelf and have always a larger front than the beſieged: and, as the beſiegers muſt extend their approaches to three fronts, whether they are ſmall or large, the work of the approaches before the front BCDE will be to the work before the front HABC, as the line BE is to the line HC, nearly, i. e. as the greater axis of the oval is to the leſs; and therefore the front CD, on the flat ſide, is ſtronger than the front AB, on the narrow ſide; conſequently, the longer CD is, ſo that the lines of defence are within the reach of muſket-ſhot, and the angles BCD, CDE, are the ſame, the ſtronger will the front be; ſince the works become more ſpacious, hold more troops to defend them, and the beſiegers are obliged to extend their trenches farther. Moreover, the greater the angles of the polygon BCD, CDE are, the exterior ſides being the ſame, the ſtronger will be the front CD; becauſe the length of the line BE increaſes, and the extent of the beſiegers approaches in proportion; and, therefore, the ſtrength of a *fortification* increaſes in proportion to the number and length of its ſides; ſo that a dodecagon is ſtronger than an octagon, when the length of their ſides is the ſame. However, as it is found difficult to inſcribe a polygon in an eliſpſe or oval, the following more eaſy method will anſwer the purpoſe. Reduce the ſpot of ground to be fortified to the figure ACEG (*fig.* 36) and draw BE, AF, parallel to each other; draw CH, DG, perpendicular to theſe lines, and at equal diſtance from the points B and E, and let their interval be equal to that of the lines BE and AF; then, draw DC, GH, parallel to AF and BE, and equally diſtant from them; and from their interſections C, D, G, H, with DG, CH, as centres, deſcribe arcs, with a radius equal to CD or GH, ſo as to interſect the lines AF, BE, in A, B, E, F; join the points A, B, E, F, and ABCDEFGH will be an oblong octagon, having one half ſimilar and equal to the other half. If a hexagon be to be deſcribed, inſtead of drawing the two lines CH, DG, one will be ſufficient; in a decagon there muſt be three, and four in a dodecagon. If the ſides cannot eaſily be made equal, then the ſides AB, EF, on the narroweſt part of the polygon, ſhould be the longeſt, becauſe it is the weakeſt. But when the figure cannot in any reſpect be made regular, the ſtrength of each ſide muſt be eſtimated according to the works a beſieger is obliged to make in the attack, and according to the obſtacles he meets with in his approaches. Muller's Elements of Fort. p. 146. &c.

FORTIFICATION, *marine*, is ſometimes uſed by way of diſtinction from *land fortification*, and denotes the art of raiſing works fit for the defence of a harbour againſt the attacks of any kind of ſhipping; but the works proper for this purpoſe depend in a great meaſure on the principles employed in the *fortification* of towns. However, attention ſhould be given to the ſituation of roads or harbours in contriving works for their defence: e. g. when a town lies open to the ſea, on a curved, or ſtrait bold ſhore, and has before it a ſufficient depth of water and good anchorage, the ſhips, in this ſituation, may be well defended by forts built near the water's edge on each ſide of the anchoring place, ſo contrived as to have two or three batteries, one higher than the other, and furniſhed with a ſufficient number of cannon, carrying ſhot from twenty-four to forty-eight pounds. A town, in this ſituation, may be defended by a rampart, or wall, well flanked, built along the ſhore, beſide the *fortifications* on the land ſide. The works along the ſhore ſhould be carried ſo near to the water's edge, that troops, attempting to land under the cannon of a fleet, might not find ground on which to intrench themſelves. Farther, when a harbour, being a bay, has a ſhoal or ſmall iſland lying before its entrance, a ſtrong fort ſhould be built upon the iſland, in a place where it can command the entrance on both ſides, if the iſland be not too large; otherwiſe two or more forts ſhould be erected in ſuch places as may command the avenues to the bay; other forts ſhould alſo be raiſed on the moſt convenient points of land, forming the mouth of the bay. Again, when the harbour is in a bay, whoſe points, forming the entrance, ſtretch into the ſea, and approach one another within cannon-ſhot; ſuch a harbour may be fortified by building on both ſides of its entrance one or more forts; and, if poſſible, a fort ſhould alſo be built within the harbour's mouth in ſuch a manner, that its cannon can rake the ſhipping fore and aft as they come in.

When a harbour is formed by a cluſter of iſlands, it is eaſily fortified, if the channel between the iſlands is not too wide for the command of cannon from one or both ſhores; but if it be too wide, the ſhipping that rides there muſt be defended from the batteries on the ſhore. When the harbour lies in an inlet, or river, ſome miles above its mouth, a fort built at each point of the entrance, when the paſſage lies ſtrait, and can be commanded from ſide to ſide, and two others between them and the harbour, but not directly oppoſite, unleſs the breadth of the channel require it, will be a proper ſecurity for the ſhipping in ſuch a harbour; and if the channel or river is winding, the forts ſhould be built where they can command a reach at leaſt, or be ſo placed as the bends, as to command two adjacent reaches. See FORTS, and Robertſon's Treat. of Marine Fort. part ii. § 2. For the *fortification* of harbours by booms, ſee BOOM.

FORTIFICATION, *durable*, is that built with deſign to remain a ſtanding ſhelter for ages. Such are the uſual *fortifications* of cities, frontier places, &c.

FORTIFICATION, *temporary*, is that erected on ſome emergent occaſion, and only for a little time.

Such are field-works, caſt up for the ſeizing and maintaining a poſt, or paſſage; thoſe about camps, &c. as circumvallations, contravallations, redoubts, trenches, batteries, &c.

The methods of *fortifying*, that have been invented, are various; and new methods continue ſtill to be propoſed. We ſhall here ſubjoin ſome of the principal and of thoſe which chiefly obtain through Europe; ſuch as thoſe of Coehorn, Pagan, Vauban, Scheiter, &c. from which all the reſt are eaſily conceived.

FORTIFICATION, *according to the Dutch method, or the ſyſtem of Alfordius*, is that which, making the flank perpendicular

dicular to the curtin, makes the flank the fubduple of the face, and fubtriple of the curtin; and the angle of the baſtion equal either to two thirds of the angle of the polygon; or to half thereof, with the addition of fifteen or twenty degrees, to make it equal to a right angle.

Freitach determines the quantity of the flank in a ſquare to be ſix; in a pentagon, ſeven; in a hexagon, eight; in a heptagon, nine; in an ennegon, ten; in a decagon, eleven; and in all other figures, twelve Rhineland perches; conſequently the face twenty-four, and the curtin thirty-ſix perches.

To draw the profile of a *fortification* after the Dutch manner: divide the ſide of the inner polygon, G H, (*Tab. Fortification, fig.* I) into five equal parts; the demi-gorge A H is to contain one of them; and the capital H C, two. Then divide the curtin E A into four parts; and make the flank A B one.

This is Freitach's method. Marolois's method of fortifying a hexagon is repreſented in *fig.* 12. Draw an indefinite right line A B; at the point A make the angle B A O equal to ſixty degrees; and as the flanked angle of the hexagon, according to Marolois, is 80°, the half flanked angle will be 40°; and let the diminiſhed angle B A D be 20°. In A D take A E=48 toiſes; and from E let fall on A B the perpendicular E N; and for the ſtuffe-bray lay down 04 toiſes from N to I, and 72 for the length of the curtin. Take I B=A N, and at I erect a perpendicular I L=N E; and drawing the line L B, this will be the face of the demi-baſtion oppoſite to A E. Draw O B, which makes an angle A B O of 60°, with A B. At the point E, and with N E produced, make the angle B E F=55°; the line E F, forming this angle, will cut O A in a point F, from which draw F M parallel to A B. Produce the perpendiculars N E, I L, to the line F M, and you will have E G and L H for the flanks of the demi-baſtions, and G H will be the curtin. If a circle be deſcribed on the centre O, with the radius O A, or A B, and a hexagon inſcribed in it, and each ſide of the hexagon be formed in the ſame manner, the work will be finiſhed; and all the meaſures may be preſerved on the front A B. We may obſerve, that Marolois makes the flanked angle of his ſquare 60°, of the pentagon 72°, of the hexagon 80°, of the heptagon 85°, and of the octagon and other polygons 90°.

FORTIFICATION, *according to De Ville's*, or the *French method*. In this method the flanked angle is always right, and the flank is equal to the demi-gorge, and perpendicular to the curtin, and the lines of defence are *ſubmiſſes*. Let A B (*fig.* 13) be the ſide of a hexagon, and divided into ſix equal parts: take A C and B D equal reſpectively to one of theſe parts for the demi-gorges of the baſtions of the front A B; at the points C and D erect the perpendiculars C I, and D H, each equal to A C or B D; theſe will be the flanks of the demi-baſtions of the front A B. Draw the radii O A and O B, and produce them indefinitely beyond A and B; on O A produced let fall a perpendicular I Q from the point I; make Q M=Q I, and draw M L, which will be the face of the demi-baſtion M L C. In the ſame manner the face H N of the other demi-baſtion may be determined; and if the ſame operations are performed with regard to the other ſides of the polygon, the *fortification* will be finiſhed. In order to cover the flank H D with an orillon, it is divided into three equal parts; G D is taken equal to one of theſe parts, and through the line G M is drawn to M, in which G K is taken equal to G D. Then the face N H is produced to meet the line M G in the point R; and on this point, as a centre, with the radius R K, an arc is deſcribed, which will interſect the face N H produced, in I. Draw the line K I, and upon this let the orillon be conſtructed, by erecting an indefinite perpendicular on I N, at the point I, within the baſtion, and another on the middle of I K towards the baſtion, which perpendiculars will interſect, and the point of their interſection will give the centre of the orillon; and if the compaſs be opened to I or K, the arc of the orillon may be deſcribed. For a ſecond flank, K G is produced from G to F, and F E is drawn parallel to G D.

FORTIFICATION, *according to De Sardi*, or the *Italian method*. This author allows 800 geometric Rhineland feet, or about 130 toiſes, to the ſide of his hexagon; which he divides into ſixteen equal parts, three of which parts he aſſumes for the demi-gorge; he makes the flank perpendicular to the curtin, and equal to the demi-gorge. He divides the curtin into eight equal parts, one of which is the ſecond flank; and through the extremity of this part, and that of the flank, he draws the face of the baſtion indefinitely; and he purſues the ſame operation with regard to the other ſide of the polygon; and the interſection of the faces gives the flanked angle of the baſtion; and he covers his flank with an orillon or epaulement.

FORTIFICATION, *according to the Spaniſh method*. The Spaniſh method is the ſame with that of De Ville, only omitting the ſecond flanks, and making the flanked angle obtuſe. In fortifying a regular polygon, they divide the ſide into ſix equal parts; they make the demi-gorges equal to one of theſe parts, the flanks perpendicular to the curtin, and equal to the demi-gorges, and the faces are drawn from the angle of the flank, and the extremity of the flanks, and their concurrence gives the flanked angle of the baſtions.

FORTIFICATION, *according to the reinforced order*. This method is aſcribed to different Italian authors, and particularly to De Marchi; and is explained in a book of *fortification* of Bourdin the Jeſuit, printed in 1665. Let any regular polygon, e. g. a hexagon, be inſcribed in a circle (*fig.* 14.) Let each of its ſides, A B, A C, be 160 toiſes; divide A B into eight equal parts, and let the demi-gorge of the baſtions, laid on from A and B, be equal to one of theſe parts. At the points D and E, which terminate the demi-gorges, erect the indefinite perpendiculars D K, E L, for the flanks of the demi-baſtion at A and B. Take D F and G E, each equal to a fourth part of A B, and at the points F and G erect the perpendiculars F H, G I, equal to the eighth part of A B, and draw the curtin H I: through the points I and F draw the line I M, terminated in M, which line will cut the perpendicular D K in K, and D K will be the face of the demi-baſtion A. K M the face, and H F the double flank of the front A B. In the ſame manner the other demi-baſtion may be conſtructed in B, and by ſimilar operations on the other ſide of the polygon, the work may be completed. This method derives its name from the diſpoſition of the flanks belonging to each front.

FORTIFICATION, *according to M. Vauban's firſt method*. This method is divided into little, mean, and great: the little is chiefly uſed in the conſtruction of citadels, and is commonly formed of pentagons; the mean in that of all ſorts of towns, from a hexagon upwards to any number of ſides; and the great only in particular caſes, chiefly of irregular *fortification*. The conſtruction of the mean, which is the moſt uſeful, is as follows: deſcribe a circle with any radius A O (*fig.* 15. N° 2.) and in this circle inſcribe a polygon of as many ſides as the *fortification* is deſigned to have fronts; e. g. a hexagon. Biſect A B, one of the ſides; which M. Vauban always ſuppoſes to be 180 toiſes, in C, and at the point C erect a perpendicular, C D, towards the centre of the polygon: when the polygon is a ſquare, C D muſt be one eighth of the ſide A B; when it is a pentagon, one ſeventh; but when it is a hexagon, or any other polygon of a greater number of ſides, C D will be one ſixth of the ſide. In this caſe, then, make C D=30 toiſes, and through D draw the indefinite lines A D G, B D F, in which take A E and F H, each equal to $\frac{1}{6}$ths of A B, or 30 toiſes, neglecting the fractions. On F, as a centre, deſcribe an arc through the point H, meeting A D in G; and on H, as a centre, deſcribe an arc through the point F, meeting D B in F; or, make each of the lines E G, H F, equal to the diſtance E H: then the lines joining the points A, E, F, G, H, B, will be the principal or outline of the front. And if the ſame conſtruction be performed on the other ſides of the polygon, we ſhall have the outline of the whole *fortification*. If with a radius of 20 toiſes, there be deſcribed circular arcs, from the angular points B, A, M, T, and lines be drawn from the oppoſite angles E, H, &c. ſo as to touch theſe arcs, their *parts* a b, b c, &c. together with theſe arcs, will repreſent the outline of the ditch. In this figure, the part F E A L N is called the BASTION, A E and A L are the FACES of the baſtion, E F and L N are the FLANKS, F G the CURTIN, F N the GORGE of the baſtion, A G and B F the lines of DEFENCE, A B the exterior ſide of the polygon, C D the *perpendicular*; any line which divides a work into two equal parts is called the CAPITAL of that work, and the COUNTERSCARP of the ditch; A and M the *flanked* ANGLES, H, F, L, the angles of the *ſhoulder* or SHOULDER, G, F, and N, the angles of the flank; any angle whoſe point turns from the place is called a SALIENT angle, ſuch as A, M, and any angle whoſe point turns towards the place, *re entering* ANGLE, ſuch as F, F, and N. If two lines be drawn parallel to the principal or outline, the one at the diſtance of three toiſes, and the other at the diſtance of eight toiſes from it, the ſpace *g e* included between the principal one, and that fartheſt diſtant, is called the RAMPART; and the ſpace *e h* contained between the principal line, and that next to it, and which is generally ſhaded black, is called the PARAPET; within four feet of the parapet there is drawn a fine line, which expreſſes a ſtep, called BANQUETTE. All works have a parapet of three toiſes thick, and a rampart of eight to ten, beſides their ſlopes. The rampart is elevated more or leſs above the level of the place,

from ten to twenty feet, according to the nature of the ground, and the particular construction of the engineer. The parapet is a part of the rampart, elevated from six to seven feet and a half above the reſt, in order to cover the troops that are drawn up there from the fire of the enemy in a ſiege; and the banquette is two or three feet higher than the rampart, or about four feet lower than the parapet; ſo that when the troops ſtand upon it, they may juſt be able to fire over the parapet. The body of the place is that which is contained within the firſt rampart; and all the works which are conſtructed beyond the ditch, before the body of the place, are called OUT-WORKS.

The following table exhibits the proportional dimenſions of the ſeveral parts in the little, mean, and great *fortification* of M. Vauban. In the firſt horizontal column are the numbers expreſſing the lengths of the exterior ſides from 80 to 260; in the ſecond, the perpendiculars anſwering to thoſe ſides; in the third, the lengths of the faces of the baſtions; and in the fourth, the lengths of the capitals of the ravelins.

TABLE.

Capital of ravelins	28	34	40	46	52	58	64	70	76	82	88	94

The principal works that are now uſed in the conſtruction of fortified places, beſide thoſe that have been already mentioned, are ARROWS, COVERT-WAYS, COUNTERGUARDS, CROWN-WORKS, DITCHES, *retired* FLANKS, GLACIS, HALF-MOONS, HORN-WORKS, LUNETTES, ORILLONS, RAVELINS, *detached* REDOUBTS, TENAILLES, and TENAILLONS.

FORTIFICATION, *according to M. Vauban's ſecond method, with tower-baſtions*, called the *ſyſtem of London*, becauſe the city of Landau is fortified after this manner. Let A B (*fig.* 16.) be the interior ſide of a hexagon, equal to 120 toiſes; draw A C, B D, from the centre, through the extremities of the ſide; ſet off 6 toiſes from A to *a*, and from B to *c*; through the points *b* and *c*, draw lines at right angles to A B; from *b* ſet off ſix toiſes to *f* outwards, and four from *b* to *d* inwards; and from the points *f* and *d*, draw perpendiculars *f r*, *d u*, to the capital A C; then if *r* E is made equal to *r f*, the point E will be the exact angle of the tower-baſtion, and E *f d n* half the tower. If in the capitals, there be taken, from the exact angles of the tower-baſtions, the diſtances E C, F D, each of forty toiſes, the points C and D will be the exact angles of the countergards before the towers. From the points C and D draw the lines of defence C *i*, D *h*, to the points where the flanks of the towers cut the curtin; on which ſet off fifty-ſix toiſes for the faces of the countergards; the flanks are found as in the firſt method, and likewiſe the tenailles. The ditch before the exact angles of the towers is ſix toiſes, and its counterſcarp drawn to the extremities of the flanks of the countergards; the right line which joins the ends of both flanks will determine the inſide of the tenailles. The ditch before the countergards is twelve toiſes at the exact angles, and the counterſcarp is drawn to the oppoſite ſhoulders in the ſame manner as in the firſt method. The capital of the ravelin is forty-five toiſes, its faces, when produced, terminate on thoſe of the countergards, within ten toiſes of the ſhoulders; ten toiſes are cut off from the faces by the flanks, which are parallel to the capital as uſual. The ditch before the ravelin is ten toiſes; the covert-way five; the ſemi-gorges of the places of arms twelve, the faces ſeventeen, and the glacis twenty. See *fig.* 17.

FORTIFICATION, *according to M. Vauban's third method*, or *that of New-Briſach*. This method is applied to an octagon, whoſe exterior ſide A B (*Tab. II. fig.* 18) is 180 toiſes, the perpendicular C D, 30; the faces A K, B L, of the countergards, 60; the flanks L N, K M, are found by ſetting off 22 toiſes, as chords to the arcs deſcribed from the oppoſite ſhoulders as centres. From the extremities of the flanks a line is drawn, which will be parallel to the exterior ſide A B, meeting the capitals A E, B F of the countergards at G and H, which line will terminate the inſide of the tenaille, and alſo the faliant angles, G, H, of the tower-baſtions. If E F be drawn parallel to G H, and at nine toiſes diſtant from it, the interſections E, F, with the capitals of the countergards, will be the centres of the towers; from which ſet off ſeven toiſes from E to *a*, and F to *b*, for the ſemi-gorges, and draw the flanks *b c*, *a m*, through the extremities of theſe ſemi-gorges, perpendicular to the line E F; theſe flanks are four toiſes inwards from *a* to *c*, and *b* to *m*, and five outwards from *a* to *b*, and *b* to *k*; the faces *b* G, *k* H, are drawn from the points *b* and *k* to G and H, and the lines joining the inſide of the flanks at the end of four toiſes, will complete the towers. The ditch is ſix toiſes before the faliant angle of the towers, and its counterſcarp meets the line G H, within ten toiſes of the extremities M, N, of the flanks of the countergards. If from the point *n*, when the line E F interſects the perpendicular C D produced, five toiſes be ſet off to the point *r*, and the lines of defence are drawn from the extremities of the ſemi-gorges *a* and *b* of the towers through this point *r*; then the flanks of the countergards produced will determine the little flanks *p*, *q*, and *s*, *t*, of the inſide rampart, and the extremities of theſe little flanks being joined, will give the curtin between them. The great ditch before the countergards is fifteen toiſes, and its counterſcarp parallel to the faces; the capital of the ravelin is fifty-five toiſes, and that of the redoubt within it twenty-three; the faces of the ravelin are drawn to the faces of the counterguard within fifteen toiſes from the ſhoulders, and thoſe of the redoubt parallel to theſe; twelve toiſes are cut off from the faces of the ravelin, and ſix from thoſe of the redoubt, by the flanks which are parallel to the capital; the ditch before the ravelin is twelve toiſes, and that before the redoubt ſix; the covert-way and glacis are the ſame as in the ſecond method. The parapets of the countergards, on both ſides of the faliant angles, are raiſed four feet higher for the ſpace of twenty feet above the reſt, in order to prevent the enfilades of the ricochet batteries. See *fig.* 19.

Mr. Muller has made ſeveral remarks on the three methods of M. Vauban above recited. With regard to the firſt he obſerves, that it is ſimple, eaſily conſtructed, and takes up but little ground, about once and a half more ground than the buildings. It is guarded from ſurprize by its ſtone retirements, requires only few men to defend it, and with the addition of ſome outworks, as countergards before the baſtions, and lunettes or tenailions to cover the ravelins, furniſhes a good defence. However, his flanks are too ſmall; his retired flanks on circular arcs of both are needleſs, ſince the flanks made upon their chords will contain as many guns, and reſiſt better than the curved flank; his capital ditch is too wide; the faces of the ravelins, inſtead of terminating on the ſhoulders of the baſtions, ſhould terminate three or four toiſes beyond them; the ſemi-gorges of the bonnet, inſtead of being fifteen toiſes, ſhould, in Mr. Muller's opinion, be but eight or ten at moſt; one of the faces of the lunettes ſhould be perpendicular to the face of the ravelin, and the other to that of the baſtion, in order to be defended in a direct manner; inſtead of the countergards before the ravelin, which are ſeldom made, he recommends a redoubt within it, as leſs expenſive, and anſwering the ſame purpoſe. All tenailions and countergards ſhould have retrenchments.

The ſecond method, he obſerves, is deſigned for fortifying an old town already incloſed by a rampart, on which account M. Vauban begins within, and fortifies outwards, contrary to his other methods; the tower baſtions are joined to the old wall, and have underneath a magazine in the form of a creſs, round which are caſemates, or cellars, to hold both men and guns; thoſe in the flanks have each an embraſure, which opens into the ditch, and thoſe in the faces have embraſures, ſo as to fire out of one into the other, when taken by the enemy, and above there is a parapet twelve feet thick, with embraſures. Theſe towers are expenſive, and afford little reſiſtance; and ſmall baſtions, without caſemates, might be ſubſtituted in their room with advantage. The flanks of the countergards are too ſmall, and are eaſily deſtroyed from the oppoſite covert-way; and, therefore, they ſhould either be enlarged or increaſed in number.

The third method differs only from the former, in having two ſmall flanks in each curtin, of about four toiſes, which can hardly hold two guns each, and, therefore, add no ſtrength.

FORTIFICATION, *according to count Pagan's method*. This author eſtabliſhes three ſorts of *fortification*; viz. the great, mean, and little, whoſe chief dimenſions are contained in the following table.

	Great Fortif.		Mean		Little	
	Square	to all the other polyg.	Square	to all the other polyg.	Square	to all the other polyg.
Exter. ſides	200	200	180	180	160	160
Perpendic.	27	30	24	30	21	30
Faces	60	60	55	55	45	50

For conſtructing the mean *fortification*, let A B (*fig.* 20.) be the ſide of a regular polygon, e. g. of a hexagon, and equal to a hundred and eighty toiſes. Biſect it in D, and erect a perpendicular equal to thirty toiſes; from the

points

points A and B, draw through C the indefinite lines of defence AN and BM; let the faces AE and BF be each equal to fifty-five toises; draw the flanks FN and EM perpendicular to the lines of defence, and MN will be the curtin. Count Pagan, in order to increase the fire of his flank, made three flanks, raised one above another, and a second baſtion within the firſt. To conſtruct theſe caſemates, as they are commonly called, biſect the flank FN in G; through the points A and G draw the line AG, and produce it indefinitely within the baſtion; produce alſo the line of defence AN; take GH=5 toiſes, and through H draw the line HI parallel to FN or GN; draw LK parallel to HI, and at the diſtance of ſeven toiſes from it, and equal to fourteen toiſes from K to L; at the diſtance of ſeven toiſes from KL draw the parallel OP, making it equal to fourteen toiſes three feet from O to P; then draw through the point P the line PQ parallel to EB; this line will be the face of the interior baſtion, having a P for its flank, and ten parapet, three toiſes thick, be conſtructed to the three flanks HI, LK, and OP. The great ditch is ſixteen toiſes, and its counterſcarp parallel to the faces of the baſtions; the capital of the ravelin fifty, and its faces are drawn to the ſhoulders: the ſemi-gorges of the redoubt within the ravelin fifteen, and the faces parallel to thoſe of the ravelin; the ditch of the ravelin twelve, and that of the redoubt ſix; the ſaliant angle of the counterguard is forty toiſes diſtant from that of the baſtion, and nine or ten broad at the extremities; the ditch before the counterguard is twelve, the covert-way four, and the faces of the place of arms eight, and parallel to the oppoſite counterſcarp. See *fig.* 21. N° 1.

This method, though at firſt received with great applauſe, has its defects; its triple flanks are too near each other; the ditch before the redoubt is but ill defended, which ſhould never be made without making tenailles likewiſe; the covert-way is too narrow, and the places of arms too inconſiderable for defending the glacis; and the want of traverſes in the covert-way is a defect, eſpecially ſince the modern diſcovery of ricochet batteries.

FORTIFICATION, *according to M. Blondel's method*, has a great affinity with that of the count de Pagan: only that the quantity of the lines and angles is differently determined. See *fig.* 22. and *fig.* 23. N° 1.

Mr. Blondel makes two ſorts of *fortification*, viz. the great, whoſe exterior ſide he makes two hundred toiſes; and the little, in which it is one hundred and ſeventy toiſes. In order to find the angles made by the exterior ſides, and the lines of defence, he directs to ſubtract 90° from the angle of the polygon, and to add 15° to the third part of the remainder, which will give the angle ſought. E. g. the angle of an hexagon is 120°, from which take 90°, and the third part of the remainder 30 is 10, which added to 15, gives the angle required. The lines of defence are equal to ⅔ of the exterior ſide, i. e. 119 or 120 in the little, and 140 in the great. The conſtruction is as follows: let AB (*fig.* 22.) the exterior ſide of a hexagon, be one hundred and ſeventy toiſes; the angles ABC, BAD, twenty-five degrees each; the lines of defence AD, BC, one hundred and twenty toiſes; let O be the point of interſection of theſe lines; biſect AO, BO, in E and H; then will AE, BH be the faces; EC, HD theſ anks; and CD the ſtraight part of the curtin. The orillons EI, LH, are ten toiſes each; the flanks are retired five toiſes behind the lines EC, HD: in all polygons above an hexagon, M. Blondel makes the retired flanks from ten to twelve toiſes diſtant from theſe lines, in order to lengthen the curtins. Each flank exceeds the flank before it nine feet in height, and they are eight toiſes diſtant from outline to outline. The counterſcarp of the ditch is drawn from the extremities I, L, of the orillons, parallel to the faces of the baſtions; the counterguards are but four toiſes broad, ten or twelve feet of which are taken for the parapet; the ditch before them is ten toiſes. If from the ſhoulder E, as a centre, an arc be deſcribed through H, and another from H through E, the interſection of theſe arcs will be in the ſaliant angle of the ravelin, the faces of which are directed to a point in the faces of the baſtions within ſix toiſes of the ſhoulders; the gorge of the ravelin is determined by producing the faces of the counterguards; the ditch of the ravelin is twelve toiſes. The ſemi-gorges of the lunettes V are twenty toiſes; their faces parallel to the counterſcarps of the ditches, before the ravelin and counterguard, and the ditch before them is eight toiſes; the covert-way 6a, and the faces of the places of arms, which are likewiſe parallel to the counterſcarps, are as much. The retired batteries, *a*, in the baſtions and ravelins, are ſeven toiſes from the faces; and their lengths are determined by the faces and counterſcarps of the ravelins and counterguards produced. This method is very expenſive, and requires a numerous artillery for defence. His three flanks are too near each other, and too open, and, therefore, liable to be deſtroyed from the covert-way, for the counter-guards are not broad enough to ſcreen thoſe flanks; the low batteries *a*, &c. are too narrow and confined; and his places of arms are too ſmall; his great ditch is too wide; and the omiſſion of traverſes in the covert-way is important, ſince the uſe of ricochet batteries.

FORTIFICATION, *according to the firſt method of baron de Cohorn.* This firſt method is applied to a hexagon, and it is ſuppoſed that the ſurface of the water is but four feet lower than the level ground. Let AB, (*Tab.* III. *fig.* 24.) the interior ſide of an hexagon, be one hundred and fifty toiſes; take AC, BD, each equal to 30, and the capitals AE, BF, each 80, and AG, BH, 40; from E and F draw the lines of defence to D and C, and through G, H, lines parallel to ED, FC, in which take GI, HK, each equal to forty toiſes, for the higheſt faces of the baſtions. For the lower faces EM, FN, draw IO (*fig.* 25. N° 2.) perpendicular to IG, and equal to four toiſes; Or parallel to IG, and =4 toiſes; then will rM, perpendicular to EM, determine the lower face EM. In order to determine the tower *s*, in rM take rS=5 toiſes; draw Sm parallel to EM and =24 toiſes; in Or produced, take rn=24 toiſes, and in EM take MV =8 toiſes; then if the points *n* and *m* are joined by a right line, and *m*, V, by an arc of 60°, we ſhall have the outline of the tower. From the points C and D (*fig.* 24.) ſet off on the lines of defence fourteen toiſes to Y and W, and on the baſes YI and WK deſcribe equilateral triangles, and the angles oppoſite to theſe baſes will be the centres of the higher flanks YI and WK; and R being the interſection of the two lines of defence, biſect RM in S, and RC in Q, and drawing SQ, QSQR will be half the tenaille; and drawing from C a line parallel to IY, ſo as to meet the tower, on this the mean flank may be deſcribed in the ſame manner as the former. The parapets of the three flanks, and thoſe of the parts nV, VM (*fig.* 25. N° 2.) of the tower, are twenty-four feet thick, the other parts Mr, *rnm*, fifteen, and all the other parapets, in general, are twenty feet. Behind the lower parapet there is a banquette of three feet, and a rampart of five, and under this rampart a ſtone gallery running from one end to the other, and divided into ſeveral apartments, which are ſhut from without; and alſo another, going from the ſaliant angle of the lower faces to that of the higher, with loop holes facing the dry ditch X, (*fig.* 24.) which lies between the higher and lower faces of the baſtions; and likewiſe a row of paliſades, parallel to the higher faces, and four toiſes diſtant from them. Before the mean flank there is a wet ditch ſix toiſes broad, and another *a* (*fig.* 25.) behind the towers of the ſame breadth, over which there are two draw-bridges, parallel to the higher faces. The ditch *a* is flanked by three embraſures in Or, and the dry ditch by two in IO. The great ditch is twenty-four toiſes broad, and its counterſcarp parallel to the lower faces of the baſtions; the ſemigorges OL of the ravelin (*fig.* 24.) are twenty-nine toiſes, and the faces LP, forty-five; the dry ditch Y is fifteen toiſes, the rampart twenty-eight feet and the lower faces a T are parallel to the higher ones, the parapet of which is twenty, and the banquette three. In the gorge of the ravelin there is a ſmall redoubt *a*, about five feet high, and underneath a lodgment of ſtones, the walls being eighteen inches thick at the ſides; the roof is made of planks, covered with three feet of earth. There is a dry ditch going from the extremities of the faces to the redoubt, and round its angle, having a row of paliſades before it to ſecure the retreat from the ravelin into this redoubt; there is likewiſe another row going from the extremities of the faces, in a round form, turning towards the gorge of the ravelin.

In the dry ditch of the ravelin, within ſix toiſes from the great ditch, is a coffer, and a ditch *p* of ſix toiſes before it: this coffer has a wall on both ſides, and the roof is planked and covered with a foot and a half of earth; above this is a ſtone parapet of five feet high, with a banquette behind it. There runs a covered gallery under the rampart of the lower faces, and another joining the two ſaliant angles, together with a row of paliſades, in the ſame manner as in the dry ditch before the baſtions. The wet ditch before the ravelin is eighteen toiſes; the counterguards *s*, which the author calls *cover-faces*, are twenty-five feet broad, and the ditch before them is fourteen toiſes; the covert-way is twelve toiſes broad, and the glacis twenty; the ſemi-gorges *f g*, *g b*, of the places of arms, are twenty-two toiſes, and are taken from the point *g*, where the branches of the covert-way meet, and the faces *f b*, *b k*, are twenty-eight; within theſe places of arms are traverſes of twenty feet thick, and eighteen toiſes long, within ten or twelve feet from, and parallel to the faces. The ſtone lodgments *b*, within the places of

of arms, are found by setting off twelve toiſes from the point *g*, for the ſemi-gorges, and the faces are drawn parallel to thoſe of the places of arms. At ſix toiſes from the places of arms, are coffers *q* of eight feet broad, made with planks at the ſides, and above with a foot of earth over and before them. There are two banquettes all round the covert-way, and before the traverſes, as alſo two rows of paliſades before the traverſes, one of which joins them, and the other goes round the covert-way. Laſtly, the re-entering angles of the counterſcarp, next to the covert-way, are made a little round, as likewiſe that in the ravelin; but the contrary way, that is, they are made hollow.

FORTIFICATION, *according to Coehorn's ſecond method.* In this method the level of the ground is ſuppoſed to be three feet above the ſurface of the water, and AB, *fig.* 26. is the interior ſide of a heptagon of a hundred and twenty-ſix toiſes; take in the capitals, AC, BD, each of ſeventy-two toiſes; at the extremities C, D, make the angles ACE, BDF, each of forty degrees; and ſet off ſixty-ſix toiſes for the faces CE, DF, of the baſtions; on the interior ſide, take AG, BH, each of thirty toiſes, and from the point D as centre, deſcribe an arc through the point G, on which ſet off a chord of thirty; and on this chord deſcribe the mean flank GI, which is an arc of ſixty degrees.

Draw a line from the ſaliant angle D through the extremity I of this flank, on which take Ia of ten toiſes; join aE, on which deſcribe the orillon as uſual.

The outline of the higher flank is twelve toiſes diſtant from that of the outline of the mean; this flank is an arc deſcribed from the ſame centre as that of the former, the chord of which is forty toiſes.

From the points G, H, draw the broken parts of the curtin perpendicular to the capital of the baſtion, and make it nine toiſes long: the extremity of the higher flank is terminated by the inſide line of the parapet of the curtin produced.

The tenaille is found by producing the faces of the baſtions ten toiſes; through the extremity of which an arc is deſcribed from the oppoſite ſaliant angle of the baſtion, as centre; on this arc is ſet off a chord of twenty toiſes; and this chord ſerves to deſcribe the flank upon, which is an arc of ſixty degrees; the curtin is a right line.

There is a wet ditch before the tenailles, of ten toiſes broad, with two bridges at each end, near the orillons; the one directly over it, and the other along the faces of the baſtion.

The dry ditch round the body of the place is twenty toiſes broad, before the faces of the baſtion to which it is parallel, and the lower rampart KL twenty-nine feet; the ſemi-gorges Am, Bm are fifteen toiſes, and the flanks LN, eighteen; and are deſcribed from the ſaliant angles K of the lower faces as centres.

The ſaliant angle of the ravelin is a hundred and twenty-five toiſes diſtant from the curtin of the body of the place, and is ſeventy degrees; the faces are fifty toiſes long; the faces of the redoubt *x*, are ſixteen toiſes diſtant from thoſe of the ravelin, and fourteen long.

The wet ditch round the lower faces of the ravelin is twenty-four toiſes broad: the work beyond this ditch, which the author calls the ſecond counterſcarp, is twenty, parallel to the ditch.

To find the broken part of this work, join the two re-entering angles m, *r*; on which take mr, of thirty toiſes, and draw rt, *r*v, parallel to the outline of the counterſcarp, each equal to twelve: ſet off twenty-two from t to *s*, and from v to q; and upon theſe lines as chords deſcribe the round flanks, which are arcs of ſixty degrees. The traverſes in this counterſcarp are drawn at ten toiſes from the flanks perpendicular to the parapet.

The redoubts *x* in the re-entering angles, are found by ſetting off ſixteen toiſes from the points m to n for their capitals, and the faces are parallel to the broken curtin before them: thoſe marked *y* which are in the ſaliant angles are found by producing the counterſcarps of the great ditch, and ſetting off twelve toiſes from the points of their interſections for their faces; and the flanks are drawn parallel to their capitals.

The ditch before this work is fourteen toiſes; as to the covert-way and glacis, they are the ſame as in the auſtrian firſt method.

FORTIFICATION, *according to Coehorn's third method.* Here the level of the ground is five feet above the ſurface of the water; and the author ſuppoſes an octagon, whoſe interior ſide AB, *fig.* 27. is a hundred and ten toiſes; the ſemi-gorges An, Bm, twenty-one; the capitals AC, BD, of the baſtions ſixty-four; and the ſaliant angles eighty-five degrees; the faces CE, DF, of the baſtions fifty-four toiſes; the parts Q*r*, Q*s*, of the tenaille thirty-two; the lower flanks, that is, thoſe of the tenaille, are found by deſcribing arcs through the points, *s*, *r*, from the oppoſite ſaliant angles DC, on which are twenty toiſes ſet off as chords; and theſe chords ſerve to deſcribe arcs of ſixty degrees upon, for the required flanks.

From the extremities v, t, of theſe flanks, lines are drawn to the oppoſite angles D, C, and ſix toiſes ſet off from v to q; and upon qE the orillon is deſcribed as uſual.

The higher flanks are deſcribed from the ſame centres, as the lower through the extremities n, m, of the curtin; and their chord is thirty toiſes.

The wet ditch before the body of the place is twenty toiſes, and its counterſcarp parallel to the faces of the baſtions.

The capital VW of the detached baſtion is a hundred toiſes; the faces are directed to the ſaliant angles of the inner baſtions; the dry ditch behind the lower faces is the detached baſtions is twenty toiſes; and the higher faces are parallel to the lower, and thirty-one toiſes long: the towers *x*, and the ditch before them are made in the ſame manner as in the firſt method. To find the flanks, make the ſemi-gorges Va, Vb, each thirty-eight toiſes, and draw the chords off theſe flanks, parallel to the capital VW; and from the extremities of the higher faces draw alſo lines to the former, upon which the flanks are deſcribed as uſual.

The counterſcarp of the ditch before the redoubt *z*, is drawn from the extremities of the flanks parallel to the faces; and at ſix toiſes from this, the faces of the redoubt are drawn: four toiſes of which are cut off from the flanks.

The ditch before the detached baſtion is twenty-four toiſes; the ravelins, counter-guards, covert-way, and glacis, are the ſame here as in the firſt method.

There are little pits or ponds l, l, dug between the higher and lower curtins, to hold water, in order to prevent the paſſing from the tenailles to the flanks.

Mr. Muller has urged a number of objections againſt Coehorn's firſt method, for which we muſt refer to his Elements of *Fortification*, p. 91, &c. and as to the ſecond and third, they are abſolutely impracticable. However, Coehorn's works were publiſhed before he had acquired that experience which afterwards rendered him one of the greateſt engineers; and Bergen-op-zoom, which he fortified, is one of the beſt contrived *fortifications* in all Europe.

FORTIFICATION, *according to the method of Scheiter.* This method is divided into the great, mean, and little: the exterior ſide of the polygon for the great ſort is two hundred toiſes, for the mean ſort one hundred and eighty, and the ſmall one hundred and ſixty. The line of defence in the firſt is one hundred and forty toiſes, in the ſecond one hundred and thirty, and in the third one hundred and twenty. This line is always ſaſant. All the other lines are fixed at the ſame length for all polygons, whoſe ſtructure chiefly depends upon the knowledge of the exterior ſide, of the capital, and of the flanked angle: for which conſult the following

TABLE *of Capitals and flanked Angles.*

Polygons	IV	V	VI	VII	VIII	IX	X	XI	XII
The flanked angles of the three ſorts of *fortification*	64	76	84	90	95	97	99	101	103
Capital for the great ſort	46	49	51	52	53	53½	56½	58	59
Ca. for the mean ſort	42	44½	46½	48½	50	51	52½	54	54
Ca. for the ſmall ſort	39	41½	43½	45	46	47	48½	50	50½

Scheiter detaches the baſtions from the curtin, and forms a kind of reccis behind the curtin: ſuppoſe an octagon to be fortified with his greater *fortification*; let AB, *(Tab.* IV. *fig.* 28.) be its exterior ſide, and equal to two hundred toiſes; AC, BD, parts of the radii, equal to forty-ſix toiſes, be the capitals, and draw the interior ſide CD: in the compaſs take a hundred and forty toiſes for the line of defence, and putting one leg in the flanked angle A, deſcribe with the other an arc to cut the interior ſide in E; make CF=ED, and draw through F and B the ſecond line of defence FB; at E and F, on the lines of defence AE and FB, erect the perpendiculars EL and FI, which, meeting the lines of defence alternately, determine the faces of the counter-guards, or detached baſtions of Scheiter. Produce the lines of defence towards the capitals, and take the parts EH and FP, each of ſixteen toiſes, and biſecting theſe lines, draw the higher flanks parallel to the lower, and make the ſame conſtruction on the other ſides; take the diſtance PQ, and with one leg of the compaſs in P, deſcribe an arc to intereſect the capital in the point N; draw NQ and NP, and the counter-guard will be finiſhed. About the counter-guard make a large ditch of eighteen toiſes, which will give the redan RST, and as the ſcarp of this ditch forms a ſaliant

faliant angle towards the middle of the curtin, Scheiter, in order to remedy this inconvenience, conſtructed there a ſmall baſtion in the following manner: from the point 3, where the lines of defence interſect one another, be let fall a perpendicular 34 on the interior ſide; and from the point 4 on each ſide, he took the diſtances 45 and 46, each equal to 42; and then drew the faces 53 and 36 of this baſtion. The flanks are drawn parallel to the perpendicular 43, and produced till they meet a parallel to P F and E H. The ditch of the counterguards is formed by producing the faces of twenty toiſes, as ZA to X, and drawing a line from X to the angle of the ſhoulder L, &c.

On the re-entering angle of the ditch, Scheiter deſcribes a kind of redoubt K, the capital of which is ſixteen toiſes; the counterguards are encompaſſed with *fauſſe-braies*, as well as the whole interior incloſure, except the faces of the ſmall baſtion in the middle of the curtins: he alſo adds a covert-way to that of the place, at the foot of the glacis of the firſt. This ſyſtem of Scheiter differs eſſentially from that which M. Vauban executed in the *fortification* of New Briſach; and yet ſome have groundleſsly charged Vauban with having borrowed his from this of Scheiter.

FORTIFICATION, *according to M. Belidor's firſt method.* Let A B, *fig.* 29. be the exterior ſide of an octagon, and equal to two hundred toiſes; the perpendicular C D, fifty; the faces A E, B F, ſeventy; and the flanks are found according to M. Vauban's method.

The line joining the extremities *a* and *b* of the flanks of the ſame baſtion, ſerves as an exterior ſide for tracing the front of a polygon, whoſe perpendicular *c d* is thirteen toiſes, the faces twenty-two; the parts *d f* of the lines of defence, which terminate the flanks, are fourteen; the dry ditch before this front is ten toiſes at the points *a*, *b*, and the counterſcarp terminates at the oppoſite ſhoulders.

The rams-horns *g*, are deſcribed from a point, in the middle of the faces of the interior front as centres, with a radius of twenty-five toiſes.

The retrenchments H, are drawn from a point h in the face at fifteen toiſes from the ſhoulder to the points *b*, *a*, and are twenty-five toiſes long; the orillons k l, eight, and the flanks m are eight toiſes retired near the orillon; which are the chords of an arc from the oppoſite ſhoulders; the ditch before theſe retrenchments is eight toiſes near the parapet of the baſtions, and its counterſcarp directed to the ſhoulders.

The faliant angle of the redoubt B touches the interſections of the curtins, produced, and the faces terminate on the faces of the inner front within three toiſes of the ſhoulders; its ditch is three toiſes: theſe redoubts are a ſtone wall of three or four feet thick, with loop-holes in the faces.

M. Belidor has made no outworks to this ſyſtem, but Mr. Muller has added ravelins and a covert-way, made in the uſual manner; the great ditch is twenty toiſes before the faliant angles of the baſtion, and its counterſcarp is directed to the ſhoulders; and the faces of the ravelins to the out-line of the retrenchments H.

FORTIFICATION, *according to M. Belidor's ſecond method.* A B, *fig.* 30. is the exterior ſide of an octagon of two hundred toiſes; the perpendicular C D, fifty-five, and the faces A E, B F, ſeventy, as in the former; and the flanks are likewiſe found according to M. Vauban's method.

The line *a b*, which paſſes through the extremities of the flanks, ſerves as an exterior ſide to the inward polygon, whoſe perpendicular c d is five toiſes, the faces twenty-four, and the flanks are chords of arcs deſcribed from the oppoſite ſhoulders of the detached baſtions as centres.

This inward polygon is nothing elſe but a ſtrong wall, behind the curtin of which, and about eighteen feet diſtance from it, is a parapet or epaulement of earth three toiſes thick; and within the baſtions are cavaliers, whoſe fronts are circular arcs deſcribed with a radius of about twenty-three or twenty-four toiſes; the flanks are ſeven toiſes long, and gorges thirty-two.

The counterſcarp of the ditch before this polygon is ſeven toiſes at the faliant angles *a*, *b*, and parallel to the curtin.

The rams-horns or tenailles touch the lines of defence within three toiſes of the ſhoulders, and are deſcribed ſo as to meet the other lines of defence in the ſame point as the counterſcarp of the inner ditch.

The outline of the curtin between the rams-horns is nine toiſes from the ditch.

The exterior ſide h k of the retrenchments within the detached baſtions, meets the faces within twenty toiſes from the ſhoulders; the perpendicular m n, is ſeventeen, the faces h l, twenty; the chord on which the orillon is deſcribed is five toiſes, as likewiſe the retired part of the flank; the flanks and orillons are made according to M. Vauban's method.

The circular curtin and the round part of the ditch behind it, are deſcribed with a centre, twenty-five toiſes diſtant from the points *a*, *b*.

The great ditch is twenty toiſes before the faliant angles of the detached baſtions, and is ſuppoſed to be dry; for which reaſon M. Belidor made a caponiere to go from the curtin to the ravelin, eighteen or twenty feet wide, whoſe parapets terminate on both ſides in a ſlope or glacis.

The capital of the ravelin Q, is ſixty-ſix toiſes, that of the redoubt P, thirty; the faces of the ravelin are directed to thoſe of the retrenchments within the baſtions, and thoſe of the redoubt to the ſhoulders; the batteries in the ravelin are retired eight toiſes behind the faces; the ditch of the ravelin is twelve toiſes, and that of the redoubt ſeven.

The ſemi-gorges of the lunettes R, are twenty-five toiſes, and the faces perpendicular to thoſe of the ravelin and the baſtion; the ditch before them is eight toiſes, and the batterics S, are retired as much, and are fifteen toiſes long: laſtly, the covert-way is ſix toiſes.

FORTIFICATION, *according to M. Belidor's third method.* The figure in this conſtruction, is part of an octagon, whoſe ſide A B, *fig.* 31. is two hundred toiſes, the perpendicular C D, forty; the faces A E, B F, fifty-five; the parts D r of the lines of defence, between the perpendicular and the broken part of the curtin, thirty; and the length of the broken parts r n, twenty-five; the orillon is nine, and is a part of a flank found according to M. Vauban's method; the flanks are eight toiſes retired, and are arcs of ſixty degrees; the outlines of the rams-horns are thirteen toiſes diſtant from each other; the paſſages at their extremities are three, the outmoſt or loweſt is deſcribed with a radius of thirty toiſes, and the other is deſcribed from the ſame centre.

Mr. Muller has omitted the cavaliers placed in the gorges of the baſtions, as being according to his notion ſuperfluous.

The centre R of the arc K L, is eighteen toiſes diſtant from the re-entering angle of the counterſcarp; the chord K L is forty-four toiſes, as well as the other face of the lunette; and the radius R K, eighty-eight; the battery H is ten toiſes retired.

The figure m is a redoubt made of a ſtone wall full of loop-holes, with a ditch of two toiſes before it.

The ditch before the lunettes is twelve toiſes at the faliant angles, and its counterſcarp directed to the extremities of the oppoſite faces.

The capital of the ravelin W is forty-four toiſes, and ſemi gorges, thirty one; the flanks are nine toiſes, and directed to the ſhoulders of the baſtions.

The ditch before the ravelin is ten toiſes, and the covert-way ſix.

The glacis T, before the faliant angles of the baſtions, is fifteen toiſes broad: the ſemi-gorges of the places of arms X are twenty-ſix toiſes; and thoſe of the redoubts or ſtone wall within them, twenty, reckoning from the edge of the glacis T; and the faces are drawn parallel to the oppoſite ſemi-gorges.

The redoubts S within the lunettes, are alſo made of a wall three or four feet thick full of loop-holes, with a ditch of three toiſes before them.

The dimenſions of the arrows and detached redoubts, are the ſame as thoſe in M. Vauban's method, only the arrows have flanks parallel to the paſſage of ten toiſes.

The ſeveral ſyſtems of Pagan, Vauban, Cochorn, Blondel, and Belidor, may be ſeen at one view in *Tab.* V. *fig.* 32.

FORTIFICATION, *according to Mr. Muller's firſt method.* Let AB, *Tab.* VI. *fig.* 33. be the exterior ſide of a polygon of any length, e. gr. a hundred and eighty toiſes; make the perpendicular C D of any length, as the ſixth, fifth or fourth part of the exterior ſide, according to the expence or importance of the place: here it is the fifth part or thirty toiſes; ſet off fifty toiſes or more for the faces B H, A E, or rather $\frac{1}{3}$ of the exterior ſide; from the faliant angle A deſcribe an arc with the radius A I of twenty toiſes, that is two or three toiſes more than the breadth of the ditch; draw from the oppoſite ſhoulder H a tangent H F to that arc, and from the angle A the indefinite line A b parallel to that tangent; then, if from the angle A as centre an arc a b be deſcribed with any radius, the flank G H is drawn parallel to the chord a b: one of the flanks being thus found, the others will be found by taking the diſtance D G, between the perpendicular and the angle of the flank, and carrying it from the extremities of all the perpendiculars on the lines of defence, as from D to F; this being done, the counterſcarp of the ditch is drawn parallel to the line H I or to A b; and having the points or re-entering angle O, its diſtance from the extremity of the perpendicular being carried all round will give the re-entering angles before the other fronts.

The tenailles h k, which M. Belidor has invented, and called them rams-horns, are defcribed, by fetting off three toifes from the fhoulder Q of the baftion to the point h, and drawing h f perpendicular to the line of defence; then its interfection f, with the other line of defence produced, will be the centre of the arc h k.

In order to conftruct the ravelin, fet off twelve or fifteen toifes from the fhoulder E to the point r, in the face of the baftion, and from the angle G of the flank as centre, defcribe an arc through the point r, meeting the perpendicular C D produced at L; from this point L draw the faces, fo as when produced to fall on the faces of the baftions within three toifes of the fhoulders; the ditch of the ravelin is twelve toifes.

For the retired flanks, find the flank Q R as before, on which fet off five or fix toifes for the fhoulder or orillons; and from a point g in the oppofite face of the baftion at five toifes from the faliant angle B, draw the broken part of the flank; then draw the retired flank parallel to the line Q R, at five toifes diftant from it: the orillon may be made round in the manner of M. Vauban's, if it be thought proper.

FORTIFICATION, *according to Mr. Muller's fecond method, with detached baftions.* Let the interior fide A B, *fig.* 34. of an octagon be a hundred and thirty toifes; take A b, B n, equal to twelve toifes for the femi-gorges of the fmall baftions, and as much for their capitals A c, B r; from the points c, r, draw the lines c n, r b, to the extremity of the gorges, and make the flanks b d, n m, perpendicular to the lines of defence; the ditch is fix toifes at the faliant angles c, r, and its counterfcarp drawn to the extremities of the flanks of the detached baftions. The capitals c C, r D, of the detached baftions are fifty-five toifes, and the lines of defence are drawn to the extremities b and n of the interior flanks; the faces are fixty; the radius of the arc, which ferves to determine the pofition of the flanks, eighteen; and the ditch fixteen at the faliant angle.

The ravelin is conftructed by defcribing an arc from the extremity of the flank, as centre, through a point in the oppofite face of the baftion, within twenty toifes of the fhoulder, which arc interfects the capital of the ravelin at the faliant angle; the faces terminate within five toifes of the fhoulders, the femi-gorge of the redoubt R is fifteen, its faces parallel to thofe of the ravelin, and its parapet two toifes; the ditch of the ravelin twelve, and that of the redoubt fix.

The femi-gorges of the places of arms are twenty toifes, thofe of the ftone redoubts p within them twelve; the faces of the places of arms are twenty-five; and thofe of the redoubts parallel to them, with a dry ditch of three toifes before them; the covert way is fix, and the glacis twenty.

The faces of the tenailles are fixteen toifes, the paffage between them and the flanks of the baftions three; their flanks are parallel to the others, the curtin is drawn through the points where they meet the lines of defence, and the infide of the tenailles is terminated by lines drawn through the extremities of the flanks of the detached baftions.

FORTIFICATION, *according to Mr. Muller's third method, with detached orillon baftions.* Let the exterior fide A B, *fig.* 35. of an octagon be two hundred toifes, the perpendicular C D forty, that is, a fifth part of the exterior fide, the faces A E, B F, fifty-five; the radius of the arc which ferves to determine the pofition of the flanks, twenty-two; the ditch fixteen at the faliant angles; the orillon five; the flank is retired five toifes; and the line k d, which terminates the flanks, is drawn from a point d, in the face at five toifes from the faliant angle; the fhoulders of the tenailles are twenty toifes from thofe of the baftions; the flanks parallel to the others, and the curtin is drawn through the points of interfection of the flanks and lines of defence.

Take on the lines F l, F h, drawn from the extremities of the faces parallel to the flanks, and which terminate the infide of the tenailles, the parts l n, h m, each of fix toifes, for the breadth of the ditch; and upon the exterior fide r n, conftruct a front of a polygon, by making the perpendicular twelve, and faces twenty toifes. The redoubts V are made of a wall three feet thick only with loop-holes; their faliant angle is determined by the counterfcarps of the inner ditch produced; and the faces terminate within three toifes of the fhoulders; the ditch about thefe redoubts is four toifes.

The ravelins and covert-way are conftructed in the fame manner as thofe in the former method.

Mr. Muller has made remarks on thefe feveral conftructions, deſigned to fhew in what refpects they are fuperior to thofe of M. Vauban, already recited. See Muller's Elem. of *Fortification*, p. 100, 104, 108, &c.

FORTIFICATION, *profile of a*, is a repreſentation of a vertical ſection of a work, ſerving to ſhew thoſe dimenſions which cannot be repreſented in plans, and are neceſſary in the building of a *fortification*. This profile is conſtructed in the following manner: provide a ſcale of equal parts, adapted to the perpendicular height of the work, e. gr. let *n b*, *Tab.* VII. *fig.* 37. be a ſcale of twenty toiſes, and let A B repreſent the level of the ground plane, ſo that thoſe parts of the *fortification* which are above the ſurface of the ground, or below it, may be above or below this line in the profile. From the point A, in the line A B, take A C = 4 toiſes three feet, for the interior talus or ſlope of the rampart; at C erect a perpendicular C D of three toiſes eighteen feet for the height of the rampart; through the point D draw an indefinite line D N parallel to A B, in which take D E = 5 toiſes for the breadth of the *terre plein* of the rampart: at the point E erect the perpendicular E F = 2 feet ſix inches for the height of the banquette, and draw F H parallel to D N, making F G and G H, each equal to three feet. Draw the line E G, which will repreſent the talus of the banquette, and G H will be the upper part of it; on the point H erect the perpendicular H I = 4½ feet from the height of the parapet above the banquette. From I draw the indefinite line I K parallel to D N, in which take I L = 1½ foot and draw H L, which will be the interior ſide of the parapet; take L K = 3 toiſes for the thickneſs of the parapet, and from the point K let fall the indefinite line K P, perpendicular to the line A B, and produce it below A B: in this line take K M = 2½ feet, and draw the line L M for the upper part of the parapet, which is a talus, that the ſoldier on the banquette may be able to diſcover the covert way and the glacis. On the point N, where D N interſects K P, as a centre, with a radius of one foot, deſcribe a ſmall ſemi-circle, which repreſents the *cordon*; take N P = 6 toiſes, and from the point P draw an indefinite line P n parallel to A B, which will repreſent the bottom of the ditch, the depth of which is ſuppoſed to be equal to the height of the rampart. Take N O = 5 feet for the thickneſs of the *revetement of the cordon*; and from the point O draw the indefinite line O Q parallel to N P: this will be the interior ſide of the *revetement* of the point P, where the line P n meets the line N P; take P R = 7 feet, or about the fifth part of its height N P, for the talus of the *revetement*, and draw the line N R, which repreſents the ſcarp or exterior ſide of the *revetement*: take R S = 1 foot for the jutting of the foundation, and draw S T perpendicular to P n, making it equal to two or three toiſes from the depth of the foundation; draw T Q parallel to P n, and let it interſect O Q in Q; and let Y & be drawn parallel to N M, and at the diſtance of three feet, for the *revetement* of the parapet. In order to repreſent the profile of the counterfort or buttreſs, when there is any, take O V = 9 feet, and draw V X parallel to O Q; V X, Q O, will repreſent this profile, by means of which the *revetement* O R is ſtrengthened. That the *terre-plein* of the rampart may have a proper declivity, for carrying away the water which falls upon it, let D W be equal to 1½ foot, and draw W E, which will repreſent the upper part of the rampart, and the line A W repreſents the ſlope of its interior ſide. Suppoſe the breadth of the ditch to be twenty toiſes, and lay this down from P to n; and on the point n erect the perpendicular n m, terminated by the line A B at m, which will be the limit of the counterſcarp. At the diſtance of three feet from this line, and parallel to it, draw z y, which will give the thickneſs of the *revetement* of the counterſcarp; n u = 3 feet will be the talus of this *revetement*, and the line u m the exterior ſide of it. The foundation may be made to terminate at the diſtance of about ſix inches from the point u. Let m c = 5 toiſes be the breadth of the covert-way, and at the point c erect a perpendicular c d = 2 feet for the height of the banquette. Draw d f parallel to A B, and equal to one toiſe, in which take d e and e f, each equal to three feet.

Draw the line c e for the talus of the banquette, and e f will be the upper part of it: from the point f erect a perpendicular f l = 4½ feet, for the height of the parapet of the covert-way above the banquette. Produce f l till it cuts A B in r; take r g = 20 toiſes for the breadth of the glacis, and draw l g, which will repreſent the glacis, or the declivity of the rampart of the covert-way: in this line take l h = 1 foot, and draw h f, which will be the interior ſide of the parapet of the covert-way; after which let there be a paliſade conſtructed on the banquette, and the profile is finiſhed. Encyclopedie.

FORTIFIED *place*, a *forteſs*, or *fortification*, i. e. a place well flanked, and ſheltered with works. See *Tab. Fortification, fig.* 21. with the explanation annexed to it, and *fig.* 38. which repreſents a *fortified* place beſieged.

Places fortified after the modern way, conſiſt chiefly of baſtions and curtins, and ſometimes of demi-baſtions, according

coding to the ſituation of the ground; of cavaliers, ramparts, fauſſe-brayes, ditches, counterſcarps, covert-ways, half-moons, ravelins, horn-works, crown-works, out-works, eſplanades, redents, and tenailles. See each under its proper article, BASTION, &c.

There are other moveable and additional parts; as hermes, parapets, banquettes, embraſures, cordons, boyaux, mouliners, chevaux de friſe, chauſſetrapes, galleries, mantelets, batteries, faps, mines, blinds, gabions, and paliſades. See each in its place, BERME, PARAPET, &c.

Several of theſe works, again, conſiſt of diverſe parts, which have different denominations: thus, a baſtion conſiſts of faces, flanks, caſemates, orillons, gorge, &c. which ſee.

FORTIN, or FORTLET, a diminutive of the word *fort*, importing a little *fort*, or ſconce, called alſo *field* FORT.

Star FORTIN, is that whoſe ſides flank each other, &c. See *Star* FORT.

FORTIORI. *A multo* FORTIORI. See MULTO.

FORTIS *Aqua*. See AQUA *Fortis*.

FORTISSIMO, in the *Italian Muſic*, is uſed to ſignify very *ſtrong*. It is ſometimes denoted by F F F or *fff*, and intimates that the performers are to play or ſing very loud or ſtrong, to expreſs ſome paſſion, &c. See FORTE.

FORTRESS. See FORT and FORTIFICATION.

FORTUNA *equeſtris*. See EQUESTRIS.

FORTUNA, in our ancient *Law-Books*, is the ſame with what we call TREASURE-*trove*.

Theſaurum dicente fortuna *invenire inquirendum eſt per 12 juratores pro rege, &c. quod fideliter præſentabunt, &c. omnes* fortunas, *abjurationes, appello*, &c.

Some pretend it alſo ſignifies *fortuite acciſus*; but this ſeems to be very fanciful.

FORTUNATE *iſlands*, in the *Ancient Geography*, an appellation which has given the critics and antiquaries great perplexity; being the name of a place famous for golden apples which grew there; or, as Varro ſays, for ſheep with golden fleeces.

The ancients deſcribe them as ſituate without the ſtreights of Gibraltar, in the Atlantic ocean. The common opinion of the moderns takes them for the Canary iſlands; this is grounded principally on the ſituation and temperature of thoſe iſlands, which render the uſe of cloaths there unneceſſary; and from the abundance of oranges, lemons, grapes, and other delicious fruits growing there.

Ol. Rudbeckis has found a very different place for them. That learned author, who makes his native country, Sweden, the ſcene of all that is great and extraordinary in ancient tradition and fable, will have the *Fortunate Iſlands* to be Sweden; and the delicious fruits, talked of by the ancients, his imagination ſuggeſts, were nothing but the virtue and good manners, which anciently flouriſhed in that cold hyperborean nation.

FORTUNE. See PROVIDENCE, FATE, &c.

FORTUNE, *Τυχη*, is a name unknown in the earlier ages; and does not occur either in Homer or Heſiod; as not being invented in their time.

In after-days it was introduced as a machine; and made to ſerve divers purpoſes in natural philoſophy and theology.

Plutarch, in an expreſs treatiſe of the *Fortune* of the Romans, accounts for the practice of the ancient poets, who ſeem to make Jupiter the author of all the evils of life. Mankind, he obſerves, before the name of *Fortune* had got into the world, perceiving a certain arbitrary cauſe, diſpoſing of things in an irreſiſtible manner, called it *God*: but the ſame cauſe being often obſerved to act at random, and without any rule or order at all, the ſupreme Being came to be diveſted of the attribute; and *Fortune*, or Deſtiny, acknowleged in his ſtead.

It is not eaſy to unravel what the ancients meant by the name *Fortune*. The Romans underſtood by it a principle of fortuity, whereby things came to paſs, without being neceſſitated thereto; but what and whence that principle is, they do not ſeem to have ever preciſely thought; whence their philoſophers are often insinuating, that men only framed the phantom *Fortune*, to hide their ignorance; and that they call *Fortune* whatever befals a man without his knowing for what purpoſe. Hence Juvenal, ſat. x. ver. 366, affirms, they were men who made a deity of *Fortune*.

Nullum numen abeſt, ſi ſit prudentia; ſed te
Nos facimus, Fortuna, deam, cœlique locamus.

The ingenious Mr. Spence gives another reading of this paſſage:

Nullum numen habes, ſi ſit prudentia; ſed te
Nos facimus, Fortuna, *deam cœlique locamus.*

This reading, he thinks, agrees beſt with the context: Juvenal ſays, ver 356, that the two things we ſhould pray for are good health and good ſenſe; that we might be the authors of our own happineſs if we pleaſed, ver. 363, that virtue is the only way to true happineſs, ver. 364, that if we ourſelves are prudent, *Fortune* has no power over us; and that, in truth, ſhe is no goddeſs at all, and has only uſurped a ſeat in heaven from the folly of mankind, ver. 366. *Fortune* was not conſidered as a deity by the old Romans, but was made ſo by the devotion and folly of the vulgar; and Mr. Spence ſays, that he has ſeen an ancient gem, in which Cybele, the mother of the gods, is repreſented as turning away her head from *Fortune*, in an attitude of diſowning and rejecting her. Polymetis. p. 150, 151, &c.

According to the opinion of the heathens, therefore, *fortune*, in reality, was only the arrival of things in a ſudden and unexpected manner, without any apparent cauſe, or reaſon; ſo that the philoſophical ſenſe of the word coincides with what is vulgarly called *chance*.

But in religion it had a farther force; altars and temples in great numbers were conſecrated to this *Fortune*, as a deity. This intimates that the heathens had perſonified, and even deified, their chance; and conceived her as a ſort of goddeſs, who diſpoſed of the fate of men at her pleaſure. Hence that invocation of Horace, *O dive, gratum quæ regis Antium*; in the thirty-fifth ode of the firſt book, where he recommends Auguſtus, then preparing for a viſit to Britain, to her protection. From theſe different ſentiments it may be inferred, that the ancients at one time took *Fortune* for a peremptory cauſe, bent upon doing good to ſome, and perſecuting others; and ſometimes for a blind, inconſtant cauſe, without any view or determination at all.

If then the word *Fortune* has no certain idea in the mouth of thoſe who erected altars to her; much leſs can it be aſcertained what it denotes in the mind of thoſe who now uſe the word in their writings.

They who would ſubſtitute the name *Providence* in lieu of that of *Fortune*, cannot give any tolerable ſenſe to half the phraſes wherein the word occurs.

Horace paints the goddeſs, preceded by Neceſſity, holding nails and wedges in her hands, with a cramp-iron, and melted lead to faſten it; rarely accompanied with Fidelity, unleſs when ſhe abandons a family; for in that caſe Fidelity never fails to depart with her, as well as friends.

She is diſreſpectfully ſpoken of by moſt of the Roman writers, and repreſented as blind, inconſtant, unjuſt, and delighting in miſchief. Ovid. ad Liv. ver. 52. ver 374. Hor. lib. i. od. 34. ver. 26. lib. iii. od. 29. ver. 51. Statius, Theb. xii. ver. 505. However, they had a good as well as a bad *Fortune*, a conſtant and inconſtant *Fortune*, the latter of which was repreſented with wings, and a wheel by her. Hor. lib. iii. od. 29. ver. 56.

Juvenal alludes to a ſtatue of *Fortune*, which exhibited her under a very good character, as the patroneſs of the poor infants that were expoſed by their parents in the ſtreets. Sat. vi. ver. 605.

The painters repreſent her in a woman's habit, with a bandage before her eyes, to ſhew that ſhe acts without diſcernment; and ſtanding on a wheel, to expreſs her inſtability. The Romans, ſays Lactantius, repreſented her with a cornucopiæ, and the helm of a ſhip, to ſhew that ſhe diſtributes riches, and directs the affairs of the world. In effect, it is with ſuch characters, that we ſee her repreſented on ſo many medals, with the inſcriptions, FORTVNA AVG. FORTVNA REDVX. FORTVNAE AVG. or REDUCIS, &c. Sometimes ſhe is ſeen pointing at a globe before her feet, with a ſceptre in one hand, and holding the cornucopiæ in the other.

The Romans had a virile, as well as a muliebrian *Fortune*, for the objects of their adoration: the *Fortuna virilis* was honoured by the men, and the *Fortuna muliebris* by the women.

They honoured *Fortune* alſo under a variety of other appellations. The Romans derived the worſhip of *Fortune* from the Greeks, under the reign of Servius Tullius, who dedicated the firſt temple to her in the public market. Nero alſo built a temple to *Fortune*. The *Fortune* worſhipped at Antium was probably of the moſt exalted character of any among the Romans; if we may judge by the account which Horace gives us of the great ſolemn proceſſions that were made to her. Hor. lib. i. od. xxiv. ver. 22. But the moſt celebrated temple of *Fortune* was at Præneſte. Statius ſpeaks of ſeveral *Fortunes* there, and calls them the *Præneſtinæ ſorores*. Lib. i. Syl. iii. ver 80.

On the reverſe of a medal of Commodus, we have a repreſentation of *Fortune*, under the quality, or ſurname of *Manens*, i. e. *ſtable, permanent*; holding a horſe by the reins. On the Greek medals we meet with ΑΓΑΘΗ or ΚΑΛΗΤΥΧΗ. *Good Fortune*. Conſtantine gave the epithet *anthouſa*, i. e. *flouriſhing*, to the *Fortune* of his new city Conſtantinople.

FORTUNE, *part of*. See PART.

FORTUNE-*tellers*. Pretenders to tell *fortunes*, and to any crafty ſciepce for the diſcovery of ſtolen goods, are puniſhable by impriſonment, pillory, and binding to their good behaviour, and ſhall be deemed vagabonds. Stat. 9 Geo. II. cap. 5. ſect. 4. Stat. 17 Geo. II. cap. 5. ſect. 2. See CONJURATION.

FORTY *days*. See QUADRAGESIMA, and LENT.

FORTY *days court*. See ATTACHMENT *of the foreſt*.

FORTY *hours, prayers of*. See HOURS.

FORTY *ſhilling-land* is uſed in Scotland for a certain portion of arable land. The *forty-ſhilling land* of old extent contains eight OXGANGS, or 104 acres.

FORUM, in *Antiquity*, is uſed in divers acceptations: ſometimes for a place of traffic, anſwering to our market-place; in which ſenſe it has uſually ſome adjective added to it, as *forum boarium*, the *beaſt-market*; *forum piſcarium*, the *fiſh-market*; *olitorium forum*, the *herb-market*.

FORUM, again, is uſed for any place, where the governor of a province convenes his people, to give judgment, according to courſe of law.

Whence a man is ſaid *forum agere*, when he keeps the aſſizes; *forum indicere*, when he appoints the place where they are to be kept, &c.

FORUM was alſo a public ſtanding place in the city of Rome, where cauſes were judicially tried, and orations delivered to the people.

Of theſe *forums* there were ſeveral; at firſt only three, viz. *Romanum*, *Julianum*, and *Auguſtum*; but that number was afterwards increaſed to ſix, by the addition of the *Tranſitorium*, called alſo *Palladium*; the *Trajanum*, and *Salluſti forum*.

The firſt, and moſt eminent of theſe, was the *forum Romanum*, called alſo *forum vetus*; and abſolutely, *forum*, or *the forum*.

In this was an apartment, called the ROSTRA, where the lawyers pleaded; the officers harangued; funeral orations were delivered, &c.

In the ſame *forum* was the *comitium*, or hall of juſtice, with the ſanctuary of Saturn, the temple of Caſtor, &c.

FORUM is alſo uſed among caſuiſts, &c. for *juriſdiction*.

Thus they ſay *in foro legis*, or the *outer forum*, i. e. in the eye of the laws, or the common courſe of juſtice: *in foro conſcientiæ*, or the *inner forum*, i. e. in the eye of God, or a man's own conſcience.

There are a great many things not condemned *in foro legis*, which yet are criminal *in foro conſcientiæ*.

FOSS, or FOSSE, in *Fortification*, &c. a DITCH, or MOAT.

The word is French, formed of the Latin participle *foſſum*, of the verb *fodio*, *I dig*.

FOSSA, *advance*. See ADVANCE.

FOSSE, *van*. See VAN.

FOSS, FOSSA, in *Anatomy*, a kind of cavity in a bone, with a large aperture, but no exit, or perforation.

When the aperture is very narrow, it is called a *ſinus*.

In the cranium there are ſix internal, and fourteen external *foſſæ*. The cavity of the orbit, which contains the eye, is a *foſſa*.

FOSS is particularly uſed for the cavity, or denture in the back part of the neck.

FOSSA *magna*, or *navicularis*, is an oblong cavity, forming the inſide of the *podendum muliebre*, and which preſents itſelf upon opening the labia; and in the middle whereof are the *carunculæ myrtiformes*. See *Tab. Anat. (Splanch.) fig. 9. lit. l.*

FOSSA, in our *Ancient Cuſtoms*, was a ditch full of water, where women committing felony were drowned: as men were hanged. *Nam & ipſi in omnibus tenementis ſuis eorum ab antiqua legalem habuere juſticiam, videlicet furcam, foſſam, furcas, & foſſas.* In another ſenſe it is taken for a grave, as appears by theſe old verſes.

Hic jacent in foſſa Berthæ venerabilis oſſa:
Hic eſt foſſatus, qui bis erat hic cathedratus.

FOSS-*way* was anciently one of the four great Roman highways of England: ſo called, according to Camden, becauſe it was ditched on both ſides, which was the Roman method of making high ways.

FOSSARII, in *Antiquity*, a kind of officers in the Eaſtern church, whoſe buſineſs was to inter the dead.

Ciaconius relates, that Conſtantine created nine hundred and fifty *foſſarii*, whom he took out of the divers colleges or companies of tradeſmen: he adds, that they were exempted from taxes, ſervices, burdenſome offices, &c.

F. Goar, in his notes on the Greek Euchologion, inſinuates, that the *foſſarii* were eſtabliſhed in the times of the apoſtles; and that the young men, who carried off the body of Ananias, and thoſe perſons full of the fear of God, who interred St. Stephen, were of the number.

St. Jerom aſſures us, that the rank of *foſſarii* held the firſt place among the clerks; but he is to be underſtood of thoſe clerks only, who had the direction and intendance of the interment of the devout.

FOSSIL, in *Natural Hiſtory*, is uſed, in a general ſenſe, for any thing dug up, or found under ground. Such are all minerals, metals, rock ſalts, &c.

Foſſils is uſed in a more confined ſenſe by Linnæus, to denote the third claſs of ſtones: and includes petrified, concrete, and terrene ſubſtances.

The chemiſts divide all bodies into three claſſes, or kingdoms; viz. *foſſil* or *mineral*, *vegetable*, and *animal*.

Foſſils may be diſtinguiſhed into, 1. Such as are *adventitious*, and of the earth: and, 2. Such as are *adventitious*, and repoſited therein by any extraordinary means; as earthquakes, deluges, &c.

FOSSILS, *native*, or FOSSILS *properly ſo called*, are ſenſible bodies, generated and growing in the earth, and found either buried in it, or lying on its ſurface; whoſe conſtituent parts are ſo ſimple and homogeneous, that there is no apparent diſtinction of veſſels and juices; nor any difference between the part, and the whole.

The firſt perſon who attempted to reduce the ſubject of *foſſils* into a regular ſcience, was Dr. Woodward, who publiſhed a method of arrangement, founded on the growth, ſtructure, and texture of *foſſils*. But this ſyſtem being found inſufficient for diſtinguiſhing the bodies of the *foſſil* kingdom with accuracy, was ſucceeded by the method of dividing theſe bodies, according to the various changes produced on them by fire, into *calcarii*, *apyri*, *vitrifcentes*, &c. eſtabliſhed by the Swediſh and German authors; and this method now univerſally prevails. The mineralogy of Wallerius is on this plan; however, other writers, as Dr. Hill, Mendes da Coſta, &c. have endeavoured to form a new ſyſtem from the combined principles of Woodward and Wallerius; and arranged *foſſils*, not only according to their growth, texture and ſtructure, but alſo their principles and qualities, as diſcovered by the aid of fire and acid menſtrua.

Native *foſſils* are either *ſimple*, or *compound*.

FOSSILS, *ſimple*, are thoſe, whoſe parts, however divided, are all of the ſame nature, i. e. of the ſame gravity, magnitude, figure, hardneſs, and mobility.

Such is quickſilver, which, however divided, is always found the ſame.

Of *foſſils* naturally and eſſentially ſimple, ſome, according to Dr. Hill, in his Hiſtory of *Foſſils*, are neither inflammable nor ſoluble in water, of which he reckons three ſeries; as thoſe of no regular ſtructure or determinate figure, comprehending the ſimple EARTHS, of which there are ſeveral orders and genera; thoſe of a regular ſtructure, and no determinate figure, of which ſeries there are three claſſes, viz. the TALCS, the FIBRÆ, and the GYPSUMS, each of which is again ſubdivided into orders and genera; and thoſe of a regular ſtructure and a determinate figure, comprehending three claſſes, viz. the SELENITÆ, CRYSTALS, and SPARS, which include various orders and genera. Other ſimple foſſils, though uninflammable, are ſoluable in water; ſuch are the ſimple SALTS: and others, on the contrary, are inflammable, but not ſoluable in water; of which there are two ſeries, viz. thoſe of a ſolid form, comprehending the PHLOGISTIÆ, and the PHLOGISTERIA.

FOSSILS, *compound*, are thoſe which may be divided into different, or diſſimilar parts.

As antimony, which may be reſolved by fire into ſulphur, and a metalline part.

Of theſe compound *foſſils*, in the diſtribution of Dr. Hill, ſome are neither inflammable, nor ſoluble in water, of which there are four ſeries; as thoſe that are found in continued ſtrata, comprehending the two claſſes of *compound* EARTHS, ſubdivided into LOAMS and MOULDS, and their ſubordinate genera; and STONES, including three orders, and under thoſe eight genera: thoſe again, that are formed in detached maſſes of a regular ſtructure and determinate figure, comprehending the two claſſes of SEPTARIÆ and SIDEROCHITÆ; thoſe formed in detached maſſes, of no determinate figure or regular ſtructure, and compoſed of a cryſtalline or ſparry matter, defended by an admixture of earth in various proportions, comprehending four claſſes, viz. the ACROPI, the *ſemipellucid* GEMS, the PEBBLES and SANDS; and thoſe that are formed of a fine pellucid ſubſtance, of great hardneſs, and never fouled by an admixture of earthy, or any other coarſe matter, but ſuſceptible of elegant tinges from metalline particles, of which ſeries there is only one claſs, including the pellucid GEMS, of which there are two genera, viz. ſuch as retain one ſimple and permanent appearance in all lights, as the diamond, the carbuncle, the ruby, the garnet, the hyacinth, the amethyſt, the ſapphire, the beryl, the emerald, the praſius, the chryſolite, and the topaz; and ſuch as exhibit variable colours, when viewed in different lights, as the opal and aſteria. Other compound *foſſils* are ſoluble in water, but not inflammable, as all the *metallic* SALTS, ſome of which are found naturally in a ſolid form, as VITRIOL and CHALCANTHUM; and others in a liquid ſtate,

ſtate, ſuch as the water from which the blue Cyprian vitriol is procured; and others are inflammable but not ſoluble in water, of which there are three claſſes, viz. the MARCASITES, the PYRITÆ, and PHLOGOMIÆ.

Dr. Hill adds a third general diviſion of *foſſils*, including the metallic *foſſils*, ſome of which are fuſible by fire, and not malleable in their pureſt ſtate; ſuch are antimony, biſmuth, cobalt, zinc, and quickſilver; and others are fuſible by fire, but concrete again in the cold, and become malleable, or diſtenſible, and ductile under the hammer: ſuch are tin, iron, copper, ſilver, lead, and gold. See STONES.

FOSSILS, *adventitious*, or *foreign*, include the ſubterraneous exuviæ of ſea and land animals, and even vegetables; as ſhells, bones, teeth, leaves, ſtalks, &c. which are found buried in great abundance, in divers parts of the earth. See *Foſſile* PLANTS, SHELLS, WOOD, &c.

Theſe extraneous *foſſils* have employed the curioſity of ſeveral of our lateſt naturaliſts, who have each their ſeveral ſyſtem to account for the ſurpriſing appearances of petrified ſea-fiſhes, in places far remote from the ſea, and on the tops of mountains; ſhells in the middle of quarries of ſtone; and of elephants teeth, and bones of divers animals, peculiar to the ſouthern climates, and plants only growing in the Eaſt, found *foſſile* in our northern and weſtern parts.

Some will have theſe ſhells, &c. to be real ſtones, and ſtone plants, formed after the uſual manner of other figured ſtones; of which opinion is our learned Dr. Liſter.

That author, though he allows of petrified ſhells on the ſea-ſhores, will by no means agree, that there are any ſuch petrifactions in the midland countries. The ſhell-like ſtones, found in our quarries, he contends, are *lapides ſui generis*; and never were any part of an animal.

His reaſons are, that their matter and texture are perfectly the ſame with that of the rock, or quarry, whence they are taken; as iron-ſtone ſhells are all iron-ſtone; ſpar, or cryſtalline, all ſpar, &c. Add, that the quarries of different ſtone yield different ſorts of theſe ſhells; and that there are no animals in nature, which yield any thing exactly like many of them.

But to this erroneous doctrine it is to be anſwered. 1. That theſe ſhells found under-ground, are often perfectly conformable to thoſe in the ſea in figure, ſubſtance, magnitude, &c. 2. The ſubſtance of theſe *foſſils* often alſo differs eſſentially from the common ſubſtance of ſtones. It is true, we frequently find them covered, or impregnated with a mineral, or ſtony matter, which has gradually inſinuated itſelf into the pores; but it is in many caſes eaſy to diſtinguiſh that matter from the ſubſtance of the ſhell.

Another opinion is, that theſe *foſſil* ſhells, with all other foreign bodies found within the earth, as bones, trees, plants, &c. were buried therein at the time of the univerſal DELUGE; and that having been penetrated either by the bituminous matter, abounding chiefly in watery places, or by the ſalts of the earth, they have been preſerved entire, and ſometimes petrified.

Others think, that thoſe ſhells, found at the tops of the higheſt mountains, could never have been carried thither by the waters, even of the deluge; inaſmuch as moſt of theſe aquatic animals, on account of the weight of their ſhells, always remain at the bottom of the water, and never move but cloſe along the ground.

They imagine, that a year's continuance of the waters of the deluge, intermixed with the ſalt waters of the ſea, upon the ſurface of the earth, might well give occaſion to the production of ſhells of diverſe kinds in different climates; and that the univerſal ſaltneſs of the water was the real cauſe of their reſemblance to the ſea-ſhells; as the lakes formed daily by the retention of rain, or ſpring-water, produce different kinds.

Others think, that the waters of the ſea, and the rivers, with thoſe which fell from heaven, turned the whole ſurface of the earth upſide down; after the ſame manner as the waters of the Loire, and other rivers, which roll in a ſandy bottom, overturn all their ſands, and even the earth itſelf, in their ſwellings and inundations; and that in this general ſubverſion, the ſhells came to be interred here, fiſhes there, trees there, &c. See Journ. des Sçavans, 1715. p. 19. and Mem. de Trev. 1713. But nobody has ſet this ſyſtem in a better light than Dr. Woodward, in his Natural Hiſtory of the Earth. That author, purſuing and improving the hypotheſis of Dr. Burnet, maintains the whole maſs of earth, with every thing belonging thereto, to have been ſo broken and diſſolved, at the time of the deluge, that a new earth was then formed in the boſom of the water, conſiſting of different ſtrata, or beds of terreſtrial matter, ranged over each other uſually, according to the order of their ſpecific gravities. By this means, plants, animals, and eſpecially fiſhes, and ſhells, not yet diſſolved among the reſt, remained mixed and blended among the mineral and *foſſil* matters; which preſerved them, or at leaſt aſſumed and retained their figures and impreſſions, either indentedly, or in relievo.

Camerarius attacks this opinion of Dr. Woodward, and goes yet higher, and advances many new notions. He ſuppoſes, 1. That the greateſt part of the ſhells now dug from under-ground, had been placed there before the deluge, that is, at the time of the creation, when God ſeparated the earth from the waters. 2. That, without having recourſe to the diſſolution of the earth by the waters, one might ſuppoſe moſt of them to have ſlipped in at the chinks and crevices naturally happening after the waters were retired, and the earth ſufficiently drained. 3. That particular inundations might have ſwept moſt of theſe ſhells into the places where we now find them. 4. That the ſea may have wrought, or caſt up, moſt of theſe ſhells through ſubterraneous ſpiracles and canals. 5. That God has created divers ſtony and metalline bodies, perfectly like the vegetables and animals, which we ſee on earth, and in the ſea.

To all theſe ſuppoſitions, Dr. Woodward anſwers, 1. That it is no ways probable, God ſhould create ſuch a number of ſhell-fiſh of the ſame ſpecies at once; and that purely with a deſign to deſtroy them all again ſo ſoon after; that among the *foſſil* ſhells of the ſame ſpecies it is eaſy to diſtinguiſh thoſe of different ages; that ſome appear preciſely ſuch as we now find them in the ſpring, the ſeaſon when the deluge began; that they are not only ſhells we find under-ground, but alſo bones of quadrupeds, plants, and trees of extraordinary ſizes, and which are not of the number of aquatics; and laſtly, that the waters were ſeparated from the earth on the third day, and that none of theſe things were created, till afterwards. 2. That, on the ſecond ſuppoſition, theſe ſhells would be diſpoſed perpendicularly, and not horizontally, as they are always found; that we ſhould ſometimes find them in the cleits of the earth, where in fact there are none but what are broken. 3. That we have no acquaintance with any of theſe pretended inundations; that they could never have brought ſhells, flags horns, and elephants teeth, from America, and the Eaſt Indies, to England, and the other parts of Europe; nor the fruits, pines, and beeches, frequently found far greater than any of our growth. Add, that theſe particular inundations muſt have riſen to the tops of the higheſt mountains, and of conſequence they muſt have been general. 4. On the fourth ſuppoſition it muſt be held, that God did not only create all theſe ſeveral bodies in the entrails of the earth, but their ſeveral parts, and the ſeparate pieces and fragments of thoſe parts; a piece of ſhell, for inſtance; one ſide of a ſhell, which conſiſts of two; a ſhell void of the fiſh it ſhould contain; beards of corn, without the grain; pieces of cedar-bark, without the wood; pieces of bullocks hides without fleſh and bones; human ſkins without bodies; a bone without the reſt of the ſkeleton; a tooth without the jaw, &c. Add, that the *foſſil* ſhells have not only external, but eſſential reſemblance to ſea-ſhells; both, e. gr. yielding, by analyſis, a quantity of ſea-ſalt; that among the *foſſil* teeth of fiſhes, we meet with ſome apparently worn; and, laſtly, that the ſhell-fiſh, called *purple*, has a long ſharp tongue, by means whereof it pierces other ſhells, and picks the fiſh out of them; and that in digging under-ground we actually meet with divers of theſe ſhells thus pierced. Can ſuch minute thorough-paced reſemblances be the accidental effects of a *luſus naturæ*? See MARINE *remains*, PETRIFACTION, *Formed* STONES, SHELLS, &c.

FOSSIL-*plant*. See PLANT.

FOSSILS, *marine*. See MARINE.

FOSSIL-*ivory*. See IVORY.

FOSSIL-*ſalt*. See SALT.

FOSSIL-*wood*. See WOOD.

FOSSORES, in *Natural Hiſtory*, a name given to a ſpecies of ſmall worms hatched from the eggs of a fly, which feeds on the parenchymatous ſubſtance of the leaves of plants, burying themſelves between the two membranes. Theſe animals in general are called by Reaumur *oſcarides*, but as they greatly differ in their ſize, and in their manner of eating and deſtroying leaves, the ſmall ones which eat but ſlowly, and gnaw their way in crooked furrows, are called by him *foſſores parvi*; and on the contrary, thoſe which eat away all that lies before them, and are of a ſomewhat larger ſize, are called *foſſores magni*. See ARCARIDES.

FOSTER *land*, in our *Old Writers*, is land given or allotted for the finding of food or victuals; as for monks in monaſteries, &c.

FOSTERLEAN, anciently ſignified nuptial gifts; much the ſame with what we now call JOINTURE.

The word is originally Saxon, and fignifies *cibarum exhibitio*, that is, a ſtipend which the wife had for her maintenance. *Poſtea ſcandum eſt cui ſolterlean pertineat, vidiet hoc Briguionia, & plegient amici ſui.*

FOTHER, or FODDER, is a weight of lead, containing eight pigs, and every pig one and twenty ſtone and a half; ſo that it is about a tun or common cart-load. Among the plumbers in London, it is nineteen hundred and a half; and at the mines it is two and twenty hundred and a half.

The word is of Teutonic origin, from *foder*.

FOTHERING, in *Sea-Language*, *is* a peculiar method of endeavouring to ſtop a leak in the bottom of a ſhip while ſhe is a float, either under ſail, or at anchor. It is uſually performed in the following manner: a baſket is filled with aſhes, cinders, and chopped rope-yarns, and looſely covered with a piece of canvas: to this is faſtened a long pole, by which it is plunged repeatedly in the water, as cloſe as poſſible to the place where the leak is conjectured to lie. The oakum or chopped rope-yarns, being thus gradually ſhaken through the twigs, or over the top of the baſket, are frequently ſucked into the hole along with the water, ſo that the leak is choaked, and the entrance of the water prevented. Falconer's Mar. Dict.

FOTOQUE, in the *Japaneſe Theology*, the name of an order of deities; the other order being called CAMIS. From the latter they obtain the bleſſings of this life, and from the former thoſe which relate to a future life.

FOTUS, in *Medicine*, the ſame as FOMENTATION.

FOUCADE. See FOUGATE.

FOVEA *cordis*, the pit of the heart, or rather of the ſtomach, called alſo *ferobiculus cordis*.

FOUGATE, FOUGASSE, or FOUGADES, in the *Art of War*, a little mine, in manner of a well, ſeldom exceeding ten feet in width, and twelve in depth; dug under ſome work, or poſt, that is like to be loſt; and charged with barrels, or ſacks of gunpowder, covered with earth. It is frequently placed before the weakeſt parts of a fortification, as the faliant angles and faces, not defended by a croſs-fire, and is ſet on fire like other mines, with a ſaucifſe.

The word is French. M. Huet derives it from *focata*, or *focus*, *fire*.

FOUL, in the *Sea-language*, is uſed when a ſhip has been long untrimmed, ſo that graſs, weeds, periwinkles, barnacles, or the like, ſtick or grow to her ſides under water. In this ſtate, ſhe is ſaid to be *foul*.

A ſhip is ſaid to make *foul water*, when, being under ſail, ſhe comes into ſuch ſhoal, or low water, that though her keel doth not touch the ground, yet ſhe comes ſo near it, that the motion of the water under her raiſes the mud from the bottom, and ſo *foults* the water.

FOUL is alſo a ſea term, importing the running of one ſhip againſt another. This happens ſometimes by the ungovernable violence of the wind, and ſometimes by the careleſſneſs of the people on board; and ſometimes happens to ſhips of the ſame convoy; ſometimes to ſuch as meet accidentally; and ſometimes to ſuch as are in port, by means of others coming in. The damages occaſioned by running *foul*, are of the nature of thoſe in which both parties muſt bear a part; they are uſually made half to fall upon the ſufferer, and half upon the veſſel which did the injury; but in caſes where it is evidently the fault of the maſter of the veſſel, he alone is to bear the damage.

FOUL *ground* of a road, bay, ſea-coaſt, or harbour, fignifies that which is rocky, or abounding with ſhallows, or otherwiſe dangerous.

FOUL *hawſe* denotes that the cables are turned round each other, by the winding or turning about of a ſhip while ſhe rides at anchor.

FOUL *wind* expreſſes that which is unfavourable, or contrary to the courſe of the ſhip, in oppoſition to large or fair.

FOUL *feeding*, in the *Manege*, denotes a voracious appetite, to which ſome horſes are ſubject, which, though not properly a diſeaſe, is the cauſe of various maladies. It is commonly the effect of ſome latent diſtemper, and frequently occaſioned by worms irritating the inteſtines. *Foul* feeders will leave their hay to eat their litter, even when it is ſoaked with their dung and urine, and diſcover a vitiated as well as a voracious appetite. The beſt remedy in caſes of this kind is to begin with purging, and to diſſolve chalk in their water, and afterwards to give them good exerciſe. The following draught will alſo ſerve to blunt their appetites: take a large handful of the roots of marſhmallows; cummin ſeeds, and fenugreek ſeeds, of each an ounce; liquorice roots ſliced, half an ounce; boil them in three pints of water, till the roots are ſoft and ſlimy; then pour off the decoction, and diſſolve in it an ounce of gum arabic, and add four ounces of linſeed oil. Let the horſe have four handfuls of this mixture every morning faſting, till his appetite abates. Care ſhould alſo be taken to keep the ſtalls as clean as poſſible. Gibſon's Farriery.

FOULDAGE. See FALDAGE.

FOULNESS *of colours*, in *Painting*, is uſed in oppoſition to brightneſs, and denotes a defect of purity. It is ſometimes called *breaking* the colour.

FOULNESS *in wounds*. When what the ſurgeon calls uncleanneſs or *foulneſs* is perceived in a wound, that is, when the fleſh in it looks fungous, black, putrid, or livid, it muſt be well cleanſed before any attempts are made to heal it. Different methods of effecting this have been in uſe at different times among the ſurgeons; the ancients uſed honey, but the moſt uſual practice now is, to apply a digeſtive ointment made of turpentine diſſolved in the yolk of an egg, and afterwards mixed with honey of roſes; but where this is not found ſtrong enough for the purpoſe, the Egyptian ointment is to be uſed, mixed either with ſpirit of wine, or with the common digeſtive. To theſe digeſtive ointments a ſmall quantity of aloes and myrrh may alſo very properly be added; and where more ſtrength is required in them, a ſmall quantity of red precipitate is to be added. The uſe of lime-water as a detergent is alſo very great, and yet more ſo, if there be added to every pint of it twenty or thirty grains of ſublimate; this makes what is called the PHAGEDÆNIC *water*. Applications of this kind are to be continued till the wound is entirely clean, and then it is to be healed with the common digeſtives, &c. Hiſter's Surgery, p. 42.

FOUMART, a name uſed in ſome parts of England for the WEASEL, called alſo, in ſome places, the *fitchet*. See POLE-*cat*.

FOUNDATION, that part of a building which is underground: or, that maſs of ſtone, &c. which ſupports a building; or upon which the walls of the ſuperſtructure are raiſed: or, it is the coffer, or bed, dug below the level of the ground, to raiſe a building upon.

The *foundation* either takes up the whole area and extent of the building, as when there are to be vaults, cellars, or the like; or it is drawn in cuts, or trenches, as when only walls are to be raiſed.

The *foundation* is properly ſo much of the maſonry, as reaches as high as the ſurface of the ground; and this is always to be proportioned to the load or weight of the building which it is to bear.

Sometimes it is maſſive, and continued under the whole building; as in the antique arches, and aqueducts, and ſome amphitheatres: more uſually it is only in ſpaces, or intervals; either to avoid expence, or becauſe the vacuities are at too great a diſtance; in which latter caſe they make uſe of inſulated pillars, bound together by arches.

That we may *found* our habitation firmly, ſays Sir H. Wotton, we muſt firſt examine the bed of earth, upon which we are to build; and then the under-ceilings, or ſubſtruction, as the ancients called it. For the former we have the general precept in Vitruvius: *Subſtructiones fundationes fodiantur, & quoad inveniri ad ſolidum, & in ſolido*: by which he recommends not only a diligent, but even jealous examination of what the ſoil will bear; adviſing us not to reſt upon any appearing ſolidity, unleſs the whole mould, through which we cut, have likewiſe been ſolid.

But how deep we ſhould go in this ſearch, he has nowhere determined, as perhaps depending more on diſcretion than regularity, according to the weight of the work; yet Palladio has ventured to reduce it to a rule; allowing for the cavaſione, i. e. the hollowing or underdigging, a ſixth part of the height of the whole fabric, unleſs there be cellars under-ground, in which caſe he would have it ſomewhat lower.

The *foundations* of buildings are either *natural* or *artificial*. *Natural*, as when we build on a rock, or a very ſolid earth; in which caſe we need not ſeek for any farther ſtrengthening. *Artificial*, where the ground is ſandy, or marſhy, or has lately been dug. In the former caſe, the architect muſt adjuſt the depth of the *foundation* by the height, weight, &c. of the building: a ſixth part of the whole height is looked on as a medium; and as to thickneſs, double that of the width of the wall, is a good rule. Architects ought to uſe the utmoſt diligence in regard to *foundations*, ſince of all errors which may happen in building, an error in this point is moſt pernicious.

The ground fit for building upon is of various kinds; ſometimes it is ſo hard as ſcarce to be cut with iron; in other places it is ſtiff, blackiſh, or whitiſh. This laſt is reckoned the weakeſt; and, in general, that is the beſt which requires moſt labour in cutting or digging.

When the ground is very bad, you muſt get large oaken piles of ſuch a length as may reach the ſound ground, and whoſe diameter muſt be about one twelfth part of their length; theſe muſt be driven down with a machine,

as close to one another as possible, and that under the middle walls as well as the outer ones; and upon their tops large planks are to be pinned down. But if the ground be only faulty in some places, arches may be turned over them, by which means no part of the weight of the building will rest upon them.

As to the rules necessary to be observed in constructing the ground-work, they are these: 1. That the bottom of the trench be made exactly level. 2. That the lowest ledge or row be all of stone, laid close together. 3. That the breadth of the ground-work be at least double that of the wall that is to be raised on it. However, art ought always to give way to discretion, for the breadth may be regulated according to the goodness of the ground, and the weight of the intended edifice. 4. That the *foundation* be made to diminish as it rises, only care must be taken that it do so equally on both sides. 5. That you ought never to build upon the ruins of an old *foundation*, unless well assured of its depth and goodness.

In some places they *found* the piers of bridges, and other buildings near the water, on sacks of wool, laid like matrasses, which, being well pressed, and greasy, will never give way; nor rot in water. See BRIDGE, CAISSON, and COFFER-DAMS.

FOUNDATION is also used figuratively for the establishment of a city, empire, or the like.

The Romans reckoned their years from the *foundation* of Rome, *ab urbe condita*; which we sometimes express by *ab U. C.* Chronologers make 745 years from the Israelites passing out of Egypt, to the *foundation* of Rome.

FOUNDATION also denotes a donation, or legacy, either in money, or lands, for the maintenance and support of some community, hospital, school, lecture, or other work of piety.

Among the order of Augustines, there is a *foundation* for the marrying of poor maids; and another for the furnishing of trusses to poor people who have ruptures, or hernias.

The founding and building of a college or hospital, is called *fundatio, quasi fundatio, or fundamenti iactatio. Ca. lib.* 10. The king only can found a college; but there may be a college in reputation founded by others. *Dyer* 267. See FOUNDER.

FOUNDAY, in *Metallurgy*, a term used by the workers at the iron-mines, in many counties of England, for the space of six days, in which time they contrive to make a determinate quantity of iron, so that they count their work by these *foundays* or weeks.

FOUNDER, he who lays a foundation, or who *founds* and endows a church, school, religious house, or other work of charity and piety.

The *founders* of churches may preserve to themselves the right of patronage, or presentation to the living. The *founder* of all corporations in the strictest and original sense is the king alone, for he only can incorporate a society; and in civil incorporations, such as Mayor and Commonalty, &c. where there are no possessions or endowments given to the body, there is no other *founder* but the king; but in eleemosynary foundations, such as colleges and hospitals, where there is an endowment of lands, the law distinguishes, and makes two species of foundation; the one *fundatio incipiens*, or the incorporation, in which sense the king is the general *founder* of all colleges and hospitals; the other *fundatio perficiens*, or the donation of it; in which sense the first gift of the revenues is the foundation, and he who gives them is in law the *founder*: but if the king and a private person join in endowing an eleemosynary foundation, the king alone shall be the *founder* of it.

FOUNDER is also an artist that melts or casts metals into various forms, for divers uses; as guns, bells, statues, bombs, types, or printing characters; and other small works, as candlesticks, buckles, &c.

The word in this sense is formed of the French *fondre*, to melt or fuse. In the Roman law they are called *flatuarii*.

From the different productions, or works of the *founders*, they are differently denominated, as *founders of small works*; *bell-founders*; *gun-founders*; *letter-founders*; *figure-casters*, &c. What belongs to each, see under FOUNDERY.

FOUNDER, in *Glass-making*, is a term appropriated to the green-glass houses, and is the person there, who in the same office in the white-glass-making is called the CONCIATOR.

FOUNDER's *furnace*. See FURNACE.

FOUNDERS, *moulds of*. See MOULDS.

FOUNDER's *press*. See PRESS.

FOUNDER, in the *Sea-language*. A ship is said to *founder* at sea, when by an extraordinary leak, or a great sea breaking in upon her, the is so filled with water, that the cannot be freed of it, nor is able to swim under it, but sinks with the weight thereof.

FOUNDERING, in the *Manege*, a disorder in horses, whereof there are two kinds, viz. in the feet, and in the chest.

FOUNDERING *in the feet*, arises from hard riding, severe labour, great heats, sudden colds, &c. which inflame the blood, and, as the farriers term it, melt the grease, and make it descend downward to the feet, and there settle; which causes such a numbness, and pricking in the hoof, that the horse has no sense of feeling in it, being hardly able to stand; or, when he does, shaking and trembling as if he had an ague.

A horse may likewise be *foundered*, by wearing straight shoes, and by travelling upon hard ground.

It may be known when he is *foundered* on his fore-feet, and not his hind feet, by his treading firmly on his hind-feet, and sparing the other; or his going crouching or crippling on his buttocks.

Sometimes, though rarely, he is *foundered* in his hind-feet, and not his fore; which is known by his seeming weak behind; and resting, as much as possible, on the fore-feet.

The general methods of curing this distemper are, first, by paring all the horse's soles so thin, that the quick may be seen; then bleeding him well at the toes; stopping the vein with tallow and resin; and then, having tacked hollow shoes on his feet, stopping them with bran, tar, and tallow, as boiling hot as may be; which is to be renewed once in two days, for a week together; after which he is to have good exercise.

Or, after he is pared thin, and let blood at the toes, his feet are to be stopped with cows-dung, kitchin-fee, tar, and foot, boiled together, and poured, boiling hot, into them.

FOUNDERING *in the chest, or body*, usually befals a horse by eating too much provender suddenly, when too hot; as also by drinking too much upon travelling, when he is hot, and riding him after it.

The effect of which is, that the body is oppressed with ill humours, which take away his strength, and put him in such condition, that he can neither go, nor bow his joints; and, being once laid, he cannot rise again, &c. his legs swell; and, soon after begin to peel; he has a dry cough, which makes his eyes water; and his nose runs with white phlegmatic matter. For the cure of this disorder, take five or six pennyworth of oil of petre and mingle it with an equal quantity of ale or beer; then rub this mixture with the hand on the part affected and at the same time hold a red hot shovel before it.

FOUNDERY, or FOUNDRY, the art of melting and casting all sorts of metals; particularly brass, iron, bell metal, &c. The word is also used for a place, or workhouse, furnished with furnaces, or forges for this purpose.

FOUNDERY *of small works, or the manner of* CASTING *in sand*. The sand used by the founders, in casting brass, &c. is yellowish, and pretty soft; but, after it has been used, it becomes quite black, because of the charcoal-dust used in the moulds. Every time they would use this sand, they work and tew it, several times over, in a bowl about a foot square, placed over a kind of trunk, or box, into which it may fall from off the board. This tewing is performed with a roller, or cylinder, about two feet long, and two inches in diameter; and a kind of knife, made of the blade of a sword: with the two instruments they alternately roll and cut the sand; and, at length, turn it down into the box or trough underneath.

Then, taking a wooden board, or table, of a length and breadth proportional to the quantity of things to be cast; round this they put a frame or ledge; and thus make a sort of mould. This mould they fill with the sand before prepared, and moderately moistened: which done, they take wooden, or metalline models, or patterns of the things intended to be cast; apply them on the mould, and press them down in the sand, so as to leave their form indented; along the middle of the mould is laid half a little cylinder of brass, which is to be the master-jet, or canal for running the metal; being so disposed, as to touch the ledge on one side, and only to reach to the last pattern on the other: from this are placed several lesser jets, or branches, reaching to each pattern, whereby the metal is conveyed through the whole frame.

This first frame being thus finished, they turn it upside down, to take out the patterns from the sand; in order to which, they first loosen them a little all round, with a small cutting instrument.

After the same manner they proceed to work the counterpart, or other half of the mould, with the same patterns, in a frame exactly like the former; excepting that it has pins, which, entering holes corresponding thereto in the other, make, when the two are joined together, the two cavities of the pattern fall exactly on each other.

The frame, being thus moulded, is carried to the founder, or melter; who, after enlarging the principal jet, or canal, of the counter-part, with a kind of knife, adding

the

be croſs jets, or canals, to the ſeveral patterns in both, and ſprinkling them over with mill-duſt, ſets them to dry in an oven.

When both parts of the mould are ſufficiently dried, they join them together, by means of the pins; and, to prevent their ſtarting, or ſlipping aſide, by the force of the metal, which is to come in flaming hot, through a hole contrived at the maſter jet, they lock them in a kind of preſs, either with ſcrews; or, if the mould be too big for this, with wedges. The moulds, thus put in the preſs, are ranged near the furnace, to be in readineſs to receive the metal as it comes out of the crucible.

While the moulds are thus preparing, the metal is put in fuſion in an earthen crucible, about ten inches high, and four in diameter.

The furnace wherein the fuſion is made, is much like the ſmith's forge; having, like that, a chimney, to carry off the ſmoke; a pair of bellows to blow up the fire; and a hearth where the fire is made, and the crucible placed. It is the uſe of this hearth, that chiefly diſtinguiſhes the furnace from the forge.

In the middle thereof is a ſquare cavity, ten or twelve inches wide, which goes to the very bottom: it is divided into two, by an iron grate: the upper partition ſerves to hold the crucible, and the fuel; and the lower to receive the aſhes.

When the fuel, which is to be of dry wood, is pretty well lighted, they put the crucible full of metal in the middle, and cover it with an earthen lid; and, to increaſe the force of the fire, beſides blowing it up with the bellows, they lay a tile over part of the aperture or cavity of the furnace.

The metal firſt put in being brought to a fuſion, they fill the crucible with pieces of braſs beaten in a mortar; to put them in they make uſe of a kind of iron ladle, with a long ſhank at the end thereof, formed into a kind of hollow cylinder, out of which the piece is dropped.

Nothing now remains, but for the founder to take the crucible out of the fire, and carry it in a pair of iron tongs (whoſe feet are bent, the better to embrace the top of the crucible), to the mould; into which he pours the melted metal, through the hole anſwering to the maſter-jet of each mould.

Thus he goes ſucceſſively, from one to another, till his crucible is emptied, or there is not matter enough left for another mould.

Then, caſting cold water on the moulds, they take the frames out of the preſſes, and the caſtworks out of the ſand: which afterwards they work again, for another caſting. Laſtly, they cut off the jets, or caſts, and ſell or deliver the work to thoſe who beſpoke it, without any farther repairing.

FOUNDERY *of ſtatues, great guns, and bells.* The art of caſting ſtatues in braſs is very ancient; inſomuch that its origin was too remote and obſcure, even for the reſearch of Pliny; an author admirably ſkilled at diſcovering the inventors of other arts.

All we can learn for certain, is, that it was practiſed, in all its perfection, firſt among the Greeks; and afterwards, among the Romans; and that the number of their ſtatues conſecrated to their gods and heroes ſurpaſſed all belief. See STATUE.

The ſingle cities of Athens, Delphos, Rhodes, &c. had each three thouſand ſtatues; and Marcus Scaurus alone, though only ædile, adorned the circus with no leſs than three thouſand ſtatues of braſs, for the time of the Circenſian games. This taſte for ſtatues was finally carried to ſuch a pitch, that it became a proverb, that in Rome the people of braſs were not leſs numerous than the Roman people.

Among us, the caſting of ſtatues was but little known, or practiſed, before the ſeventeenth century.

As to the *caſting of guns*, it is quite modern; and it were, perhaps, to be wiſhed, we were as ignorant of it as the ancients. All authors agree, that the firſt cannon were caſt in the fourteenth century; though ſome affix the event to the year 1338, and others to 1380. See CANNON and GUNNERY.

The *caſting of bells* is of a middle ſtanding, between the other two. The uſe of bells is certainly very ancient in the weſtern church; and the ſame were likewiſe once uſed in the church of the Eaſt. But, at preſent, F. Vanſleb aſſures us, in his ſecond account of Egypt, he had found but one bell in all the eaſtern church, and that in a monaſtery in the Upper Egypt. See BELL.

The matter of theſe large works is rarely any ſimple metal, but commonly a mixture of ſeveral. We ſhall here give the proceſs in the *foundery* of each.

Method of caſting ſtatues, or figures. See BRONZE.

There are three things chiefly required in caſting of ſtatues, buſts, baſſo-relievos, vaſes, and other works of ſculpture: viz. the mould, the wax, and ſhell, or coat.

The inner mould, or core (thus called from *cœur*, as being in the heart or middle of the ſtatue,) is a rude lumpiſh figure, to which is given the attitudes and contours of the ſtatue intended: it is raiſed on an iron grate, ſtrong enough to ſuſtain it; and is ſtrengthened withinſide by ſeveral bars, or ribs, of iron.

It may be made at the diſcretion of the workmen; of potters clay, mixed up with horſe-dung and hair; or of plaiſter of Paris, mixed with fine brickduſt.

The uſe of the core in ſtatues is to ſupport the wax and ſhell, to leſſen the weight and to ſave metal. In bells it takes up all the inſide, and preſerves the ſpace vacant where the clapper is hung. In great guns it forms the whole chace, from the mouth to the breech: and, in mortars, the chace, and chamber. The iron bars and the core are taken out of the braſs figure, through an aperture left in it, which is afterwards ſoldered up: but it is neceſſary to leave ſome of the iron bars of the core that contribute to the ſteadineſs of the projecting parts, within the braſs figure.

The wax is a repreſentation of the intended ſtatue. If it be a piece of ſculpture, the wax muſt be all of the ſculptor's own hand, who uſually faſhions it on the core itſelf; though it may be wrought ſeparately, in cavities, moulded, or formed, on a model, and afterwards diſpoſed and arranged on the ribs of iron over the grate, as before; filling the vacant ſpace in the middle with liquid plaſter, and brick-duſt; by which means the inner mould, or core, is formed in proportion as the ſculpture carries on the wax.

When the wax (which is to be of the intended thickneſs of the metal) is finiſhed, they fix little waxen tubes perpendicularly to it, from top to bottom; to ſerve, both as jets, for the conveyance of the metal to all parts of the work: and as vent-holes, to give paſſage to the air, which would, otherwiſe, occaſion great diſorder, when the hot metal came to encompaſs it. By the weight of the wax uſed herein, is that of the metal adjuſted; ten pounds of this laſt being the proportion to one pound of the former.

The work brought thus far, wants nothing but to be covered with its ſhell; which is a kind of coat, or cruſt, laid over the wax; and which, being of a ſoft matter, and even, at firſt, liquid, eaſily takes and preſerves the impreſſion of every part thereof; which it afterwards communicates to the metal, upon its taking the place of the wax, between the ſhell and the core. The matter of this outer mould, or ſhell, is varied according as different layers, or ſtrata, are applied. The firſt is a compoſition of clay, and old white crucibles, well ground and ſifted, and mixed up with water, to the conſiſtence of a colour fit for painting: accordingly, they apply it with a pencil, laying it ſeven or eight times over, letting it dry between whiles. For the ſecond impreſſion, they add horſes dung and natural earth to the former compoſition. The third impreſſion is only horſes dung and earth. Laſtly, the ſhell is finiſhed by laying on ſeveral more impreſſions of this laſt matter, made very thick with the hand.

The ſhell, thus finiſhed, is ſecured and ſtrengthened by ſeveral bands, or girts, of iron, wound around it at half a foot's diſtance from one another, and faſtened at bottom to the grate under the ſtatue; and at the top to a circle of iron, where they all terminate.

Here it muſt be obſerved, that if the ſtatue be ſo big, that it would not be eaſy to move the moulds, when thus provided, it muſt be wrought on the ſpot where it is to be caſt.

This is performed two ways; in the firſt, a ſquare hole is dug under-ground, much bigger than the mould to be made therein, and its inſides lined with walls of freeſtone, or brick. At the bottom is made a hole, of the ſame materials, with a kind of furnace, having its aperture outwards: in this is a fire to be lighted, to dry the mould; and, afterwards, to melt the wax. Over this furnace is placed the grate; and on this the mould, &c. framed as above explained. Laſtly, at one of the edges of the ſquare pit is made another large furnace, to melt the metal, as hereafter mentioned.

In the other way, it is ſufficient to work the mould above-ground; but with the ſame precaution of a furnace, and grate, underneath: when finiſhed, four walls are to be run up round it: and, by the ſide thereof, a maſſive made, for a melting furnace. For the reſt, the method is the ſame in both. The mould being finiſhed, and incloſed between four walls, whether under-ground, or above it, a moderate fire is lighted in the furnace under it, and the hole covered with planks, that the wax may melt gently down, and run out at pipes contrived for the purpoſe, at the foot of the mould; which are afterwards very exactly cloſed with earth, as ſoon as all the wax is carried off.

This done, the hole is filled up with bricks thrown in at random, and the fire in the furnace is augmented till ſuch

time as both the bricks and the mould become red-hot; which ordinarily happens in twenty-four hours. Then, the fire being extinguished, and every thing cold again, they take out the bricks, and fill up their place with earth, moistened, and a little heaven, to the top of the mould, in order to make it the more firm and steady.

Things being in this condition, there remains nothing but to melt the metal, and run it into the mould: this is the office of the furnace above, which is made in manner of an oven, with three apertures; one to put in the wood; another for a vent; and a third to run the metal out at. From this last aperture, which is kept very close whilst the metal is in fusion, a little tube or canal is laid, whereby the melted metal is conveyed into a large earthen bason over the mould; into the bottom of which all the big branches of the jets, or cafts, which are to carry the metal into all the parts of the mould, are inserted.

It must be added, that these jets are all terminated, or stopped with a kind of plugs, which are kept close, that upon opening the furnace, the brafs which guffies out like a torrent of fire, may not enter any of them till the bason be full enough of matter to run into them all at once; upon which occasion they pull out the plugs, which are long iron rods, with a head at one end, capable of filling the whole diameter of each tube. The beds of the furnace is opened with a long piece of iron, fitted at the end of a pole; and the mould is then filled in an instant. The work is now finished, at least so much as belongs to the casting, the rest being the sculptor's, or carver's business; who, taking the figure out of the mould and earth with which it is encompassed, takes off the jets, wherewith it appears covered over; and repairs it, with instruments proper to his art; as chiffels, gravers, puncheons, &c.

FOUNDERY. *The manner of casting bells.* What has been hitherto shewn of the casting of statues, bells, in proportion of the casting of bells; that which is particular in these latter, in an follows: first, then, the metal is different; there being no tin in the metal of statues, but no less than a fifth part of tin in that of bells. Secondly, the dimensions of the core, and the wax of bells, especially if it be a ring of several Bells that is to be cast, are not left to chance, or the caprice of the workman; but must be measured, on a kind of scale, or DIAPASON; which gives the height, aperture, and thickness, necessary for the several tones required.

It need not be added, that it is on the wax, that the several mouldings and other ornaments, and inscriptions, to be represented in relievo, on the outside of the bell, are formed. The clapper, or tongue, is not properly a part of the bell, but is furnished from other hands. In Europe, it is usually of iron, with a large knab at the extreme; and is fastened in the middle of the bell. In China, it is only a huge wooden mallet, struck by force of arm against the bell; whence they can have but little of that consonancy to much admired in some of our rings of bells. The Chinese have an extraordinary way of increasing the sound of their bells; viz. by leaving a hole under the cannon; which our bell founders would reckon a defect.

The proportions of our bells differ very much from those of the Chinese. In ours, the modern proportions are, to make the diameter fifteen times the thickness of the brim, and the height twelve times. The parts of a bell are 1. the sounding bow, terminated by an inferior circle, which grows thinner and thinner. 2. The brim or that part of a bell whereon the clapper strikes, and which is thicker than the rest. 3. The outward sinking of the middle of the bell, or the point under which it grows wider to the brim. 4. The waist or furniture, and the part that grows wider and thicker quite to the brim. 5. The upper vate, or that part which is above the waist. 6. The pales which supports the staple of the clapper within. 7. The bent and hollowed branches of metal uniting with the cannons, to receive the iron keys, whereby the bell is hung up to the beam which is its support and counterpoise, when rung out. The business of bell-*foundery* is reducible to three particulars. 1. The proportion of a bell. 2. The forming of a mould. And, 3. the melting of the metal. There are two kinds of proportions, viz. the simple and the relative; the former are those proportions only that are between the several parts of a bell to render it sonorous; the relative proportions establish a requisite harmony between several bells. The method of forming the profile of a bell, previous to its being cast, in which the proportion of the several parts may be seen, is as follows: the thickness of the brim, C1 (See *Tab. Miscellan. fig.* 12.) is the foundation of every other measure, and is divided into three equal parts. First, draw the line HD, which represents the diameter of the bell; bisect it in F, and erect the perpendicular F1; let DF and HF be also bisected in E and G, and two other perpendiculars Ee, Gg, be erected at E and G: Gg will be the diameter of the top or upper vase, i. e. the diameter of the top will be half that of the bell: and it will, therefore, be the diameter of a bell which will sound an octave to the other. Divide the diameter of the bell, or the line HD into fifteen equal parts, and one of these will give C1 the thickness of the brim; divide again each of these fifteen equal parts into three other equal parts, and then form a scale. From this scale take twelve of the larger divisions or $\frac{4}{5}$ of the whole scale in the compass, and setting one leg in D, describe an arc to cut the line Ee in N, draw ND, and divide this line into twelve equal parts; at the point 1 erect the perpendicular 1C = 10, and C1 will be the thickness of the brim = $\frac{1}{5}$ of the diameter: draw the line CD: bisect DN and at the point of bisection 6 erect the perpendicular 6K = $1\frac{1}{6}$ of the larger divisions on the scale. With an opening of the compass equal to twice the length of the scale or thirty brims, letting one leg in N, describe an arc of a circle, and with the same leg in K, and the same opening describe another arc to intersect the former: on this point of intersection, as a centre, and with a radius equal to thirty brims, describe the arc NK: in 6 K produced take KB = $\frac{2}{3}$ of the larger measure of the scale, or $\frac{2}{5}$ of the brim, and on the same centre with the radius 30 brims describe an arc AB parallel to NK. For the arc BC, take twelve divisions of the scale, or twelve brims in the compass, find a centre, and from that centre, with this opening describe the arc BC, in the same manner as NK or AB were described. There are various ways of describing the arc Kp; some describe it on a centre as the distance of nine brims from the points p and K; others, as it is done in the figure, on a centre at the distance only of seven brims from those points. But it is necessary first to find the point p, and to determine the rounding of the bell p 1. For this purpose, on the point C as a centre and with the radius C1 describe the arc 1 p m; bisect the part 1, 2 of the line D1, and erecting the perpendicular pn, this perpendicular will cut the arc 1 p h in m, which terminates the rounding 1 p. Some founders make the bendings K a third of a brim lower than the middle of the line DN; others make the part C1 D more acute, and instead of making C1 perpendicular to DN at 1, draw it $\frac{1}{3}$th of a brim higher, making it still equal to one brim; so that the line 1 D is longer than the brim C1. In order to trace out the top-part No, take in the compass eight divisions of the scale or eight brims, and on the points N and D, as centres, describe arcs to intersect each other in 8; on this point 8, with a radius of eight brims describe the arc Nh; this arc will be the exterior curve of the top or crown; on the same point 8, as a centre and with a radius equal to $7\frac{1}{2}$ brims, describe the arc Ar, and this will be the interior curve of the crown, and its whole thickness will be one third of the brim. As the point 8 does not fall in the axis of the bell, a centre M may be found in the axis by describing with the interval of eight brims on the centres D and H arcs which will intersect in M; and this point may be made the centre of the inner and outer curves of the crown, as before. The thickness of the cap, which strengthens the crown at Q, is about one third of the thickness of the brim; and the hollow branches or ears about one fifth of the diameter of the bell. The height of the bell is in proportion to its diameter, as twelve to fifteen, or in the proportion of the fundamental sound to its third major; whence it follows, that the sound of a bell is principally composed of the sound of its extremity or brim, as a fundamental, of the sound of the crown which is an octave to it, and of that of the height which is a third. Encyclopedie, Art. CLOCHE. See BELL.

The particulars necessary for making the mould of a bell, are, 1. The earth: the most cohesive is the best; it must be well ground and sifted, to prevent any chinks. 2. Brick-stones which must be used for the mine, mould, or core, and for the furnace. 3. Horse-dung, hair, and hemp, mixed with the earth to render the cement more binding. 4. The wax for inscriptions, coats of arms, &c. 5. The tallow equally mixed with the wax, in order to put a slight lay of it upon the outer mould, before any letters are applied to it. 6. The coals to dry the mould.

For making the mould, they have a scaffold consisting of four boards, ranged upon trestles. Upon this they carry the earth, gently diluted, to mix it with horse-dung, beating the whole with a large spatula.

The compasses of construction are the chief instrument for making the mould, which consist of two different legs, joined by a third piece. And last of all, the founders shelves,

shelves, on which are the engravings of the letters, cartridges, coats of arms, &c.

They first dig a hole of a sufficient depth to contain the mould of the bell, together with the case, or cannon, under ground, and about six inches lower than the terre-plein, where the work is performed. The hole must be wide enough for a free passage between the mould and walls of the hole; or between one mould and another, when several bells are to be cast. At the centre of the hole is a stake erected, that is strongly fastened in the ground. This supports an iron-peg, on which the pivot of the second branch of the compasses turns. The stake is encompassed with a solid brick-work, perfectly round, about half a foot high, and of the proposed bell's diameter. This they call a mill-stone. The parts of the mould are the core, the model of the bell, and the shell. When the outer surface of the core is formed, they begin to raise the core, which is made of bricks that are laid in courses, of equal height, upon clay of plain earth. At the laying of each brick, they bring near it the branch of the compasses, on which the curve of the core is shaped, so as that there may remain between it and the curve the distance of a line, to be afterwards filled up with layers of cement. The work is continued to the top, only leaving an opening for the coals to bake the core. This work is covered with a layer of cement, made of earth and ho se-dung, on which they move the compasses of construction, to make it of an even smoothness every where.

The first layer being finished, they put the fire to the core, by filling it half with coals, through an opening that is kept shut, during the baking, with a cake of earth, that has been separately baked. The first fire consumes the flake, and the fire is left in the core half, or, sometimes, a whole day: the first layer being thoroughly dry, they cover it with a second, third, and fourth; each being smoothed by the board of the compasses, and thoroughly dried before they proceed to another.

The core being completed, they take the compasses to pieces with intent to cut off the thickness of the model, and the compasses are immediately put in their place, to begin a second piece of the mould. It consists of a mixture of earth and hair, applied with the hand on the core, in several cakes that close together. This work is finished by several layers of a thinner cement of the same matter, smoothed by the compasses, and thoroughly dried, before another is laid on. The last layer of the model is a mixture of wax and grease spread over the whole. After which are applied the inscriptions, coats of arms, &c. besmeared with a pencil dipped in a vessel of wax on a chafing-dish: this is done for every letter. Before the shell is begun, the compasses are taken to pieces, to cut off all the wood that fills the place of the thickness to be given to the shell.

The first layer is the same earth with the rest, sifted very fine; whilst it is tempering in water, it is mixed with cow's hair, to make it cohere. The whole being a thin cullis, is gently poured on the model, that fills exactly all the smoothies of the figures, &c. and this is repeated till the whole is two lines thick over the model. When this layer is thoroughly dried, they cover it with a second of the same matter, but something thicker: when this second layer becomes of some consistence, they apply the compasses again, and light a fire in the core, so as to melt off the wax of the inscriptions, &c.

After this they go on with other layers of the shell, by means of the compasses. Here they add to the cow's hair a quantity of hemp, spread upon the layers, and afterwards smoothed by the board of the compasses. The thickness of the shell comes to four or five inches lower than the mill-stone before observed, and surrounds it quite close, which prevents the extravasation of the metal. The wax should be taken out before the melting of the metal.

The ear of the bell requires a separate work, which is done during the drying of the several incrustations of the cement. Of his seven rings, the seventh is called the bridge, and unites the others, being a perpendicular support to strengthen the cores. It has an aperture at the top, to admit a large iron-peg, bent at the bottom; and this is introduced into two holes in the beam, fastened with two strong iron-keys. There are models made of the rings, with moulds of beaten earth, that are dried in the fire, in order to have the hollow of them. These rings are gently pressed upon a layer of earth and cow's hair, one half of its depth; and then taken out, without breaking the mould. This operation is repeated twelve times for twelve half-moulds, that two and two united may make the hollow of the six rings: the same they do for the hollow of the bridge, and bake them all, to unite them together.

Upon the open place left for the coals to be put in, are placed the rings that constitute the ear. They first put into this open place the iron-ring to support the clapper of the bell; then they make a round cake of clay, to fill up the diameter of the thickness of the core. This cake, after baking, is clapped upon the opening, and soldered with a thin mortar spread over it, which binds the cover close to the core.

The hollow of the model is filled with an earth, sufficiently moist, to fix on the place, which is strewed, at several times, upon the cover of the core; and they beat it gently with a pestle, to a proper height; and a workman smooths the earth at top with a wooden trowel dipped in water.

Upon this cover, to be taken off afterwards, they assemble the hollows of the rings. When every thing is in its proper place, they strengthen the outside of the hollows with mortar, in order to bind them with the bridge, and keep them steady at the bottom, by means of a cake of the same mortar, which fills up the whole aperture of the shell. This they let dry, that it may be removed without breaking, to make room for the metal they pull off the hollows of the rings, through which the metal is to pass, before it enters into the vacuity of the mould. The shell being unloaded of its ear, they range under the mill-stone five or six pieces of wood, about two feet long, and thick enough to reach almost the lower part of the shell; between these and the mould they drive in wooden wedges with a mallet, to shake the shell of the model whereon it rests, so as to be pulled up, and got out of the pit.

When this and the wax are removed, they break the model and layer of earth, through which the metal must run, from the hollow of the rings, between the bell and the core. They smoke the inside of the shell, by burning straw under it, that helps to smooth the surface of the bell. Then they put the shell in the place, so as to leave the same interval between that and the core; and before the hollows of the rings or the cap are put on again, they add two vents, that are united to the rings, and to each other, by a mass of baked cement. After which they put on this mass of the cap, the rings, and vents, over the shell, and solder it with thin cement, which is dried gradually by covering it with burning coals. Then they fill up the pit with earth, beating it strongly all the time round the mould.

The furnace has a place for the fire, and another for the metal. The fire place has a large chimney, with a spacious ash-hole; the furnace which contains the metal is vaulted, whose bottom is made of earth, rammed down; the rest is built with brick. It has four apertures; the first, through which the flame reverberates; the second is closed with a stopple, that is opened for the metal to run; the others are to separate the dross, or scorie, of the metal by wooden rakes; through these last apertures passes the thick smoke. The ground of the furnace is built sloping, for the metal to run down. See Dict. Commerc. Eng. edit. art. FOUNDERY.

FOUNDERY. *Manner of casting great guns, or pieces of artillery.* The casting of cannons, mortars, and other pieces of artillery, is performed much like that of statues, and bells; especially as to what regards the wax, shell, and furnaces.

All pieces of artillery are now cast solid, and bored afterwards by means of a machine invented at Strasburgh, (*see Boring of* CANNON) and much improved by Mr. Verbruggen, the present head-founder at Woolwich. The gun to be bored was at first placed in a perpendicular position; but the machines used for this purpose have lately been made to bore horizontally, and much more exactly than those that bore in a vertical situation. Whilst the inside is bored, the outside is turned and polished at the same time.

As to the metal it is somewhat different from both; as having a mixture of tin, which is not in that of statues; and only having half the quantity of tin that is in bells, i. e. at the rate of ten pound of tin to a hundred of copper. The respective quantities of different metals that should enter into the composition for brass cannon is not absolutely decided; the most common proportions of the ingredients are the following, viz. to 240lb of metal fit for casting, they put 68lb of copper, 52lb of brass, and 12lb of tin. To 4200lb of metal fit for casting, the Germans put 3687½lb of copper, 204½lb of brass, and 307½lb of tin. Others, again, use 100lb of copper, 6lb of brass, and 9lb of tin; and lastly, others make use of 100lb of copper, 10lb of brass, and 15lb of tin. See CANNON.

A cannon is always shaped a little conical, being thickest of metal at the breech, where the greatest effort of the gunpowder is made, and diminishing thence to the muzzle;

ale; so that if the mouth be two inches thick of metal, the reech is six. See CANNON.

Its length is measured in calibers, i. e. in diameters of the muzzle. Six inches at the muzzle require twenty calibers, or ten feet in length; there is always about the sixth of an inch allowed play for the ball. For the parts, and their respective proportions of different sorts of guns, see CANNON and GUN. The method of casting iron cannon differs very little from that of brass.

FOUNDERY, *Letter, or the mystery of casting printing letters.* The invention of printing letters we shall speak of under PAINTING and LETTER.

Their difference, kind, &c. have already been explained under the articles CHARACTER, &c.

In the business of cutting, casting, &c. letters for printing, the letter-cutter must be provided with a vice, hand-vice, hammers and files of all sorts for watchmakers use; as also gravers and sculpters of all sorts, and awl-stone, &c. suitable and sizeable to the several letters to be cut: a flat gage made of box to hold a rod of steel, or the body of a mould, &c. exactly perpendicular to the flat of the using-file: a sliding gage, whose use is to measure and set off distances between the shoulder and the tooth, and to mark it off from the end, or from the edge of the work; a face-gage, which is a square notch cut with a file into the edge of a thin plate of steel, iron, or brass, of the thickness of a piece of common tin, whose use is to proportion the face of each sort of letter, viz. long letters, ascending letters, and short letters. So there must be three gages, and the gage for the long letters is the length of the whole body supposed to be divided into forty-two equal parts. The gage for the ascending letters Roman and Italic are $\frac{7}{8}$ or 30 parts of 42, and 33 parts for the English face. The gage for the short letters is $\frac{3}{7}$ or 18 parts of 42 of the whole body for the Roman and Italic, and 22 parts for the English face.

The Italic and other standing gages are to measure the scope of the Italic stems, by applying the top and bottom of the gage to the top and bottom lines of the letters, and the other side of the gage to the stem; for when the letter complies with these three sides of the gage, that letter has its true shape.

The next care of the letter-cutter is to prepare good steel punches, well tempered, and quite free from all veins of iron; on the face of which he draws or marks the exact shape of the letter, with pen and ink, if the letter be large; or with a smooth blunted point of a needle, if it be small; and then with sizeable and proper shaped and pointed gravers and sculpters, digs or sculps out the steel between the strokes or marks he made on the face of the punch, and leaves the marks standing on the face. Having well shaped the inside strokes of his letter, he deepens the hollows with the same tools: for if a letter be not deep in proportion to its width, it will, when used at press, print black, and be good for nothing. This work is generally regulated by the depth of the counter-punch. Then he works the outside with proper files till it be fit for the matrice.

But, before we proceed to the sinking and justifying of the matrices, we must provide a mould to justify them by, of which you have a draught in *Tab. Miscellany, fig.* 13, 14.

Every mould is composed of an upper and an under part. The under part is delineated in *fig.* 13. The upper part is marked *fig.* 14. and is in all respects made like the under part, excepting the stool behind, and the bow, or spring, also behind: and excepting a small roundish wire between the body and carriage, near the break where the under part hath a small rounding groove made in the body. This wire, or rather half-wire, in the upper part, makes the nick in the shank of the letter, when part of it is received into the groove in the under part. These two parts are so exactly fitted and gaged into one another (viz. the male gage, marked e in *fig.* 14. into the female marked g in *fig.* 13.) that when the upper part of the mould is properly placed on, and in the under part of the mould, both together make the entire mould, and may be slid backwards for use so far, till the edge of either of the bodies on the middle of either carriage comes just to the edge of the female gages, cut in each carriage: and they may be slid forwards so far, till the bodies on either carriage touch each other: and the sliding of these two parts of the mould backwards makes the shank of the letter thicker, because the bodies in each part stand wider asunder, and the sliding them forwards makes the shank of the letter thinner, because the bodies on each part of the mould stand closer together.

The parts of the mould are as follow: viz.

a The carriage.
b The body.
c The male gage.
d e The mouth-piece.
f i The register.
g The female gage.
h The bag.
a a a a The bottom plate.
b b b The wood, on which the bottom plate lies.
c c c The mouth.
d d The throat.
e d d The pallat.
f The nick.
g g The stool.
h h The spring or bow.

Then the mould must be justified: and first the founder justifies the body, by casting about twenty proofs, or samples of letters: which are set up in a composing stick with all their nicks towards the right hand; and then by comparing these with the pattern letters, set up in the same manner, he finds the exact measure of the body to be cast. He also tries if the two sides of the body are parallel, or that the body be no bigger at the head than at the foot; by taking half the number of his proofs, and turning them with their heads to the feet of the other half; and if then the heads and the feet be found exactly even upon each other, and neither to drive out nor get in, the two sides may be pronounced parallel. He further tries whether the two sides of the thickness of the letter be parallel by first letting his proofs in the composing stick with their nicks upwards; and then turning one half with their heads to the feet of the other half: and if the heads and feet lie exactly upon each other, and neither drive out nor get in, the two sides of the thickness are parallel.

The mould thus justified, the next business is to prepare the matrices. A matrice is a piece of brass or copper of about an inch and a half long, and of a thickness in proportion to the size of the letter it is to contain. In this metal is sunk the face of the letter intended to be cast, by striking the letter punch about the depth of an n. After this the sides and face of the matrice must be justified and cleared, with files, of all bunchings made by sinking the punch.

Every thing thus prepared, it is brought to the furnace which is built of brick upright, with four square sides and a stone on the top, in which stone is a wide round hole for the pan to stand in. A *foundery* of any consequence has several of these furnaces in it.

As to the metal of which the types are to be cast, this, in extensive founderies, is always prepared in large quantities; but cast into small bars, of about twenty pounds weight, to be delivered out to the workmen as occasion requires. In the *letter foundery* which has been long carried on with reputation, under the direction of Dr. Alex. Wilson, and sons, at Glasgow, we are informed, that a flock of metal is made up at two different times of the year, sufficient to serve the callers at the furnace for six months each time. For this purpose a large furnace is built under a shade, furnished with a wheel vent, in order the more equally to heat the sides of a strong pot of cast iron which holds, when full, fifteen hundred weight of the metal. The fire being kindled below, the bars of lead are let softly down into the pot, and their fusion promoted by throwing in some pitch and tallow, which feed inflame. An outer chimney, which is built so as to project about a foot over the farthest lip of the pot, catches hold of the flame by a strong draught, and makes it act very powerfully in melting lead; whilst it serves at the same time to convey away all the fumes, &c. from the workmen, to whom this laborious part of the business is committed. When the lead is thoroughly melted, a due proportion of the regulus of antimony and other ingredients are put in, and some more tallow is inflamed, to make the whole incorporate sooner. The workmen now having mixed the contents of the pot very thoroughly, by stirring long with a large iron ladle, next proceed to draw the metal off into the small troughs of cast iron which are ranged, to the number of fourscore, upon a level platform, faced with stone, built towards the right hand. In the course of a day fifteen hundred weight of metal can be easily prepared in this manner; and the operation is continued for as many days as are necessary to prepare a flock of metal, of all the various degrees of hardness. After this the whole is disposed into presses, according to its quality, to be delivered out occasionally to the workmen.

The founder must be now provided with a ladle, which differs nothing from other iron ladles, but in its size. And he is provided always with ladles of several sizes, which he uses according to the size of the letters he is to cast. Before the caster begins to cast, he must kindle his fire in the furnace to melt the metal in the pan. Therefore he takes the pan out of the hole in the stone, and

there

there lays in coals and kindles them; and, when they are well kindled, he fets the pan in again and puts in metal into it to melt: if it be a fmall-bodied letter he calls, or is thin letter of great bodies, his metal muft be very hot; may fometimes red-hot, to make the letter come. Then having chofe a ladle that will hold about as much as the letter and break are, he lays it at the ftoking-hole, where the flame burfts out, to heat. Then he ties a thin leather cut with its narrow end againft the face to the leather groove of the matrice, by whipping a broom-ftraw twice about the leather-groove, and faftening the ftraw with a knot. Then he puts both halves of the mould together, and puts the matrice into the matrice-cheek, and places the foot of the matrice on the ftool of the mould, and the broad end of the leather upon the wood of the upper half of the mould, but not high up, left it might hinder the foot of the matrice from finking clofe down upon the ftool in a train of work. Then laying a little rofin on the upper wood of the mould, as drawing his caftingladle hot, he with the boiling-fide of it melts the rofin; and, when it is yet melted, preffes the broad end of the leather hard down on the wood, and fo fattens it to the wood: all this is the preparation.

Now he comes to caft. Wherefore placing the under half of the mould in his left hand, with the hook or handle of it downwards, he clutches the end of its wood between the lower part of the ball of his thumb and his three middle fingers: then he lays the upper half of the mould upon the under half, fo that the male gages may fall into the female gages, and at the fame time the foot of the matrice places itfelf upon the ftool; and, clafping his left hand thumb ftrong over the upper half of the mould, he nimbly catches hold of the bow of caring with his right hand fingers at the top of it, and his thumb under it, and places the point of it againft the middle of the matrice, in the backfide of the matrice, carrying it as well forwards towards the mould, as downwards, by the fhoulder of the notch clofe upon the ftool, while at the fame time with his hinder fingers, as aforefaid, he draws the under half of the mould towards the ball of his thumb, and thruffs by the ball of his thumb the upper part towards his fingers, that both the regifters of the mould may preis againft both fides of the matrice, and his thumb and fingers preis both halves of the mould clofe together.

Then he takes the handle of his ladle in his right hand, and with the ball of it gives a ftroke, two or three, outwards upon the furface of the melted metal, to fcum or clear it from the drofs that may fwim upon it; then takes up the ladle full of metal, and having his mould as aforefaid, in his left hand, he a little twifts the left fide of his body from the furnace, and brings the gout of his ladle (full of metal) to the mouth of the mould, and twills the upper part of his right hand towards him to turn the metal into it, while at the fame moment of time he jilts the mould in his left hand forwards, to receive the metal with a ftrong ftuke (as it is called); not only into the bodies of the mould, but while the metal is yet hot running, fwift and ftrongly, into the very face of the matrice, to receive its perfect form there, as well as in the ftunk.

Then he takes the upper half of the mould off the under half, by placing his right hand thumb on the end of the wood next his left hand thumb, and his two middle-fingers at the other end of the wood; and finding the letter and break lie in the under half of the mould (as moft commonly by reafon of its weight it does) he throws or tofles the letter, break and all, upon a ftunt of waftepaper laid for that purpofe on the bench, juft a little beyond his left hand, and is then ready to caft another letter as before; and alfo, the whole number that is to be caft with that matrice.

A workman will ordinarily caft about three thoufand of thefe letters in a day.

When the cakes at the furnace have got a fufficient number of types upon the tables, a fet of boys come, and nimbly break away the jets from them: the jets are thrown into the pots, and the types are carried away in parcels to other boys, who rub them fwiftly under their fingers, defended by leather, upon fmooth flat ftones, in order to polifh their broad-fides. This is a very dextrous operation, and is a remarkable inftance of what may be effected by the power of habit and long practices for thefe boys, in turning up the other fide of the type, do it fo quickly by a mere touch of the fingers of the left hand, as not to require the leaft perceptible intermiffion in the motion of the right hand upon the ftone. The types, thus finely fmoothed and fattened on the broad-fides, are next carried to another fet of boys, who fit at a fquare table, two on each fide, and there are ranged up on long rulers, or fticks, fitted with a fmall projection, to hinder them from fliding off backwards. When thefe fticks are fo filled, they are placed, two and two, upon a fet of wooden pins fixed into the wall, near the dreffer, fometimes to the amount of a hundred, in order to undergo the finifhing operations. This workman, who is always the moft expert and skilful in all the different branches carried on at the *foundery*, begins by taking one of thefe fticks, and, with a peculiar addrefs, fmites the whole column of types off upon the dreffing-ftick: this is made of well-ieafoned mahogany, and furniftied with two ruft pieces of fteel, a little lower than the body of the types, one of which is moveable, fo as to approach the other by means of a long fcrew-pin, inferted in the end of the ftick. The types are put into this ftick with their faces next to the back or projecting end of the other, and adjufted to one another fo as to ftand even; they are then bound up, by forcing home the moveable end-piece. It is here where the great and requifite accuracy of the moulds comes to be perceived; for in this cafe the whole column is bound up, lies flat and true upon the ftick, the two extreme types being quite parallel, and the whole has the appearance of one long continuous plate of metal. The leaft inaccuracy in the exact parallelifm of the individual types, when multiplied by many times, would render it impoffible to bind them up in this manner, by difpofing them to rife or fpring from the ftick by the fmalleft preffure from the fcrew. Now, when lying fo conveniently with the narrow edges uppermoft, which cannot poffibly be fmoothed in the manner before mentioned by the ftones, the workman does this more effectually by fcraping the furface of the column with a thick-edged but fharp razor, which at every ftroke brings on a very fine fmooth fkin, like to polifhed filver; and thus he proceeds till in about half a minute he comes to the farther end of the ftick. The other edges of the types are next turned upwards, and polifhed in the fame manner. It is whilft the types thus lie in the dreffing-ftick that the operation of beating or bruing is performed, which is effected by running a fine, fteel inftrument, along the fhoulder of the body next to the face, which takes more or lefs off the corner, as occafion may require. Whilft in the dreffing-ftick they are alfo grooved, which is a very material operation. In order to underftand this, it muft be remembered, that when the types are firft broken off from the jets, fome fuperfluous metal always remains, which would make them bear very unequally againft the paper whilft under the printing-preis, and effectually mar the impreffion. That all thefe inequalities may therefore, be taken away, and that the bearings of every type may be regulated by the fhoulders impanted to them all alike from the mould, the workman or dreffer proceeds in the following manner. The types being fcrewed up in the ftick, as before mentioned, with the jet end uppermoft, and projecting beyond the wood about one eighth of an inch, the ftick is put into an open preis, fo as to prefent the jet-end uppermoft, and then every thing is made faft by driving a long wedge, which bears upon a flip of wood, which lies clofe to the types the whole length: then a plough or plane is applied, which is fo conftructed as to embrace the projecting part of the types between its long fides, which are made of polifhed iron. When the plane is thus applied, the fteel cutter beating upon that part between the fhoulders of the types, where the inequalities lie, the dreffer dextrouly glides it along, and by this means ftrips off every irregular part that comes in the way, and fo makes an uniform groove the whole length, and leaves the two fhoulders ftanding; by which means every type becomes preciftly like to another, as to the height againft paper. The types being now finifhed, the ftick is taken out of the preis and the whole column replaced upon the other ftick; and after the whole are fo dreffed he proceeds to pick out the laft letters, previous to putting them up into pots and papers. In doing this he takes the ftick into his left hand, and turning the faces near to the light, he examines them carefully, and whenever an imperfect or damaged letter occurs, he nimbly plucks it out with a fharp bodkin, which he holds in the right hand for that purpofe. Thofe letters which, from their form, project over the body of the type, and which cannot on this account be rubbed on the ftones, are fcraped on the broad-fides with a knife or file, and fome of the metal next the face pared away with a penknife, in order to allow the type to come clofe to any other. This operation is called kerning.

The excellence of printing types conſiſts not only in the due performance of all the operations above defcribed, but alſo in the hardneſs of the metal, form, and fine proportion of the character, and in the exact bearing and ranging of the letters in relation to one another.

FOUND-

FOUNDLING *hospital*. See *Foundling* HOSPITAL.

FOUNT, or FONT, among *Printers*, &c. a set, or quantity, of CHARACTERS, or LETTERS, of each kind, cast by a letter-founder, and sorted.

We say, a founder has cast a *fount* of pica, of english, of pearl, &c. meaning that he has cast a set of characters of these kinds.

A complete *fount* does not only include the running letter, but also majuscules, or large and small capitals, single letters, double letters, points, commas, lines, borders, head-pieces, tail-pieces, and numeral characters.

Founts are large or small, according to the demand of the printer, who orders them by the hundred weight, or by sheets. When the printer orders a *fount* of five hundred, he means that the *fount* shall weigh five hundred pounds. When he demands a *fount* of ten sheets, it is understood, that with that *fount* he shall be able to compose ten sheets, or twenty forms, without being obliged to distribute. The founder takes his measures accordingly; he reckons a hundred and twenty pounds for a sheet, including the quadrats, &c. or fifty pounds for a form, which is half a sheet: not that the sheet always weighs a hundred and twenty pounds, or the form fifty pounds; on the contrary, it varies according to the size of the form; besides, it is always supposed that there are letters left in the cases.

The letter-founders have a kind of list, or tariff, whereby they regulate their *founts*: the occasion thereof is, that some letters being in much more use, and oftener repeated, than others, their cells, or cases, should be better filled and stored, than those of the letters which do not return so frequently.

Thus the *a*, and *i*, for instance, are always in greater quantity than the *k*, or *z*.

This difference will be best perceived from a proportional comparison of those letters with themselves, or some others. Suppose a *fount* of a hundred thousand characters, which is a common *fount*; here the *a* should have five thousand; the *e*, three thousand; the *r*, eleven thousand; the *i*, six thousand; the *m*, three thousand; the *k*, only thirty; and the *x*, *y*, and *z*, not many more. But this is only to be understood of the letters of the lower case; those of the upper having other proportions, which it would be, here, too long to insist on.

FOUNTAIN, FONS, in *Philosophy*, a spring, or source, of water, rising out of the ground.

For the phenomena, theory, origin, &c. of springs, or *fountains*, see SPRING.

Among the ancients, the *fountains*, or sources of rivers, were held sacred, and even worshipped, as a kind of divinities.

Seneca observes as much, in his forty-first epistle; and Cicero, lib. iii. De Nat. Deor. cap. 20. mentions, that the Roman priests, and augurs, used, in their prayers and invocations, to call on the names of the Tyber, and other rivers, brooks, and springs, about Rome. And the seventh inscription, in p. 94. of Gruter, has *FONTI DIVINO ET GENIO NUMINIS FONTIS*.

It was a point of religion, not to disturb, or make muddy, these waters in washing or bathing: Tacitus gives an instance hereof in Nero, Annal. lib. xiv. cap. 22.

FOUNTAIN, or *artificial* FOUNTAIN, in *Hydraulics*, a machine or contrivance, whereby water is violently spouted, or darted up; called also a *jet d'eau*. See JET *d'Eau*, FLUID, &c.

There are divers kinds of artificial *fountains*; some founded on the spring, or elasticity of the air; and others, on the pressure, or weight, of the water, &c.

The structure of each of these being pretty and curious, and affording a good illustration of the doctrine of hydraulics, and pneumatics, shall be here explained.

The theory of *fountains* may be collected from the articles AIR, FLUID, &c. and other particulars relating to their ajutages, and pipes of conduct, &c. may be found under JET *d'Eau*, and *Motion of* WATER.

FOUNTAIN. *Construction of an artificial* FOUNTAIN, *playing by the spring, or elasticity of the air.* A vessel, proper for a reservoir, as A B, *Tab.* II. *Hydraulics*, *fig.* 24 is provided, of metal, glass, or the like, ending in a small neck *c*, at the top: through this neck a tube is put, *c d*, traversing the middle of the vessel, till its lower orifice *d*, nearly, but not absolutely, reach the bottom of the vessel; the vessel being first half filled with water. The neck is so contrived, as that a syringe, or condensing pipe, may be screwed upon the tube; by means whereof a large quantity of air may be intruded through the tube into the water, out of which it will disengage itself, and emerge into the vacant part of the vessel, and lie over the surface of the water C D.

Now, the water here contained being thus pressed by the air; which is, e. gr. twice as dense as the external air; and the elastic force of air being equal to its gravitating force; the effect will be the same, as if the weight of the column of air over the surface of the water were double that of the column pressing in the tube: so that the water must, of necessity, spout up, through the tube, when the syringe is removed, with a force equal to the excess of pressure of the included, above that of the external air.

FOUNTAIN. *Construction of an artificial* FOUNTAIN, *playing by the pressure of the water.* Having the convenience of a fund, or reservoir of water, in a place considerably higher than that where the *fountain* is to be (whether that fund hath been placed there by nature, or whether it hath been raised for the purpose, by a proper engine, as a pump, siphon, spiral screw, or the like): from the reservoir lay vertical tubes, for the water to descend through; and, to these vertical tubes, fit other horizontal ones, under ground, to carry the water to the place, where the *fountain* is to play. Lastly, from these horizontal tubes, erect other vertical ones, by way of ajutages, jets, or spouts, their altitude being much less than that of the tubes whereby the water was carried to the horizontal ones.

Then will the water, by the pressure of the superincumbent column, be spouted up at these jets; and that to the height, or level, of the water in the reservoir; and this will be the case, however any of the tubes be bent or incurvated. The demonstration hereof, see under FLUIDS.

Thus may water be spouted to any given height at pleasure; and the tubes may be so proportioned as to yield any given quantity of water, in a given time; or several tubes, of the same *fountain*, may be made to yield water in any given ratio; or, lastly, different tubes may project the water to different altitudes. Rules for all which, the reader will find among the laws of FLUIDS and JETS *d'Eau*.

These aerial or aquatic *fountains* may be applied in various manners, so as to exhibit various appearances; and from these alone, arises the greatest part of our artificial water-works. An instance, or two, will not be disagreeable.

FOUNTAIN *spouting the water in various directions.* Suppose the vertical tube, or spout, in which the water rises, to be AB (*Tab.* II. *Hydraulics*, *fig.* 25.) into this fit several other tubes; some horizontal, others oblique; some inclining, others reclining, as OP. MN, FL, &c.

Then, as all water retains the direction of the aperture through which it is spouted, that issuing through A will rise perpendicularly; and that through L, H, N, P, E, will describe arches of different magnitudes, and tending different ways.

Or thus: suppose the vertical tube AB, *fig.* 26. through which the water rises, to be stopped at the top, as in A; and, instead of pipes, or jets, let it be only perforated with little holes all round, or only round half its surface: then will the water spin forth, in all directions, through the little apertures, and to a distance proportional to the height of the fall of the water.

And hence, if the tube A B be supposed the height of a man, and be furnished with an epistomium, or cock, at C, upon opening the cock, the spectators will be covered unexpectedly with a shower.

It must be here observed, that the diameters of the apertures by which the water is emitted, must be considerably less than those of the tubes in which the water is brought, lest the resistance of the air, and other impediments, specified under FLUID and JET *d'Eau*, break the force of the water.

FOUNTAIN *playing by the draught of the breath.* Suppose AB, *Tab.* II. *fig.* 27. a glass, or metalline sphere, wherein is fitted a tube CD, having a little orifice in C, and reaching almost to D, the bottom of the sphere. If, now, the air be sucked out of the tube CD, and the orifice C be immediately immerged under cold water, the water will ascend through the tube into the sphere.

Thus proceeding, by repeated exactions, till the vessel be above half full of water, and then applying the mouth to C, and blowing air into the tube, upon removing the mouth the water will spout forth.

Or, if the sphere be put in hot water, the air, being thereby rarefied, will make the water spout as before.

This kind of *fountain* is called *Pila Heronis*, or Hero's ball, from the name of its inventor.

FOUNTAIN, *the stream whereof raises and plays a brass ball.* Provide a hollow brass ball A, *Tab.* III. *Hydraulics*, *fig.* 28, made of a thin plate, that its weight may not be too great for the force of the water. Let the tube BC, through which the water rises, be exactly perpendicular to the horizon.

Then the ball, being laid in the bottom of the cup, or bason, B, will be taken up in the stream, and sustained at a considerable height, as A, alternately vibrating, or playing up and down.

Hence, as the figure of the ball contributes nothing to its reciprocal rise and fall, any other body, not too heavy, may be substituted in lieu thereof; e. gr. a bird, with its wings stretched forth.

But note, that, as it is necessary the ball, when on the descent, should keep the same precise perpendicular wherein it rose (since, otherwise, it would miss the stream, and fall downright), such a *fountain* can only be played in a place free from wind.

FOUNTAIN *which spouts water in form of a flower.* To the tube whereon the water is to rise, fit a spherical, or lenticular head, A B, *fig.* 29 made of a plate of metal, and perforated at the top with a great number of little holes.

The water rising with vehemence towards A B, will be there divided into innumerable little threads, and afterwards broke, and dispersed into the finest drops.

FOUNTAIN *which spreads the water in form of a table-cloth.* To the tube A B, *fig.* 30. solder two spherical segments, C and D, almost touching each other, with a screw E, to contract or amplify the interstice or chink, at pleasure.

Others chuse to make a smooth, even cleft, in a spherical or lenticular head, fitted upon the tube.

The water spouting through this chink or cleft will expand itself in manner of a cloth.

FOUNTAINS, *wherein the water spouts out of the figures of men, and other animals.* Since water may be derived, or conveyed, by tubes in any situation, and always retains the direction of the aperture, all here required is, to inclose tubes within the figures of men, or other animals, having their orifices in those parts whence the water is intended to spout forth.

From the principles hitherto laid down, it will be very easy to deduce whatever relates to the furniture of *fountains*, and the various forms water may be put into by their means; all depending on the magnitude, figure, and direction, of the ajutages, or apertures.

FOUNTAIN, *which when it has done spouting, may be turned like an hour-glass.* Provide two vessels A and B, *fig.* 31. to be so much the bigger as the *fountain* is to play the longer; and placed at so much the greater distance from each other, as the water is desired to spout the higher. Let C D E be a crooked tube, furnished in E with a jet; and G H I another bent tube, furnished with a jet in I; K L, and G F are to be other lesser tubes, open at both ends, and reaching near to the bottom of the vessels B and A, to which the tubes G H and C D are likewise to reach.

If, now, the vessel A be filled with water, it will descend through the tube C D; and will spout up through the jet E, by the pressure of the column of water C D. But unless the pipe G F was open at G, to let the air run up to F, and press at the top of the surface of the water in the cavity A, the water could not run down and spout at E. After its fall again, it will sink through the little tube K L, into the vessel B, and expel the air through the tube G I. At length, when all the water is emptied out of the vessel A, by turning the machine upside down, the vessel B will be the reservoir, and make the water spout up through the jet I, the pipe K L supplying B with air to let the water descend in the direction G H I.

Hence, if the vessels A and B contain just as much water as will be spouted up in an hour's time, we shall have a spouting clepsydra, or water-clock; which may be graduated, or divided, into quarters, minutes, &c. as shewn under CLEPSYDRA.

FOUNTAIN *of command.* This depends on the same principles with those of the former: C A E, *fig.* 32. is a vessel of water secured against the entrance of the air, except through the pipe G F, when the cock C, by which it was filled, is shut. There is another pipe E D H B, which goes from the bottom of the water to the jet B in the basin D B, but this is stopped by the cock H. At the lowest part of the basin D B, there is a small hole at I to let the water of the basin D B run into the basin G H under it; there is also a small triangular hole, or notch, in the bottom of the pipe F G, at G. Turn the cock H, and the *fountain* will play for some time, then stop, then play again alternately for several times together. When these times of playing and stopping are known before-hand, you may command the *fountain* to play or stop, whence its name. The cause of this phenomenon is as follows: the water coming down the pipe E D H B, would not come out at B, if the air S 2, above the water, was not supplied as it diluted: now it is supplied by the pipe G F, which takes in at the notch G, and delivers it out at F; but after some time the water, which has spouted out at B, falling down into the basin D B, rises high enough to come above the notch G, which stops the passage of the air; so that the air S 2, above the water in the vessel C A E, wanting a supply, cannot sufficiently press, and the *fountain* ceases playing. But when the water of D B has run down into the lower basin H G, through the hole I, till it falls below the top of the notch G, the air runs up into the upper receptacle, and supplies that at S 2, and the *fountain* plays again. This is seen a little before-hand, by a thin of water on the notch G, before the air finds a passage, and then you may command the *fountain* to play. It is evident, that the hole I must be less than the hole of the jet, or else all the water would run out into the lower basin, without rising high enough to stop the notch G.

FOUNTAIN *that begins to play when the lighting of candles, and ceases as they go out.* Provide two cylindrical vessels, A B and C D, *fig.* 33. connect them by tubes, open at both ends, K L, B E, &c. so that the air may descend out of the higher into the lower; to the tubes solder candlesticks, H, &c. and to the hollow cover of the lower vessel, C E, fit a little tube, or jet, F G, furnished with a cock G, and reaching almost to the bottom of the vessels. In G let there be an aperture, furnished with a screw, whereby water may be poured into C D.

Then, upon lighting the candles H, &c. the air in the contiguous tubes becoming rarefied thereby, the water will begin to spout through G F.

By the same contrivance may a statue be made to shed tears upon the presence of the sun, or on the lighting of a candle, &c. all here required being only to lay tubes from the cavity wherein the air is rarefied, to some other cavities placed near the eyes, full of water.

A FOUNTAIN may be made by the rarefaction of the air in the following manner: let A B and C D, *fig.* 34. be two pipes fixed to a brass head C, made to screw into a glass vessel E, which, having a little water in it, is inverted till the pipes are screwed on; then reverting it suddenly, so as to put A, the lower end of the spouting pipe A B into a jar of water A, and the lower end of the descending pipe C D, into a receiving vessel D, the water will spout up from the jar A into the tall glass vessel E, from which it will go down at the mouth C, through C D, into the vessel D; till the water is wholly emptied out of A, making a *fountain* in E, into D. The reason of the play of the *fountain* is this: the pipe C D, being two foot nine inches long, lets down a column of water, which rarefies the air $\frac{1}{4}$ part in the vessel E, where it presses against the water spouting at B with $\frac{1}{4}$ of the force by which the water is pushed up at the hole A, by the pressure of the common air on the water in the vessel A; so that the water spouts up into E, when the air is rarefied $\frac{1}{4}$ with the difference of the pressure of the atmosphere, and the forementioned rarefied air; i. e. of 33 to 24. This would raise the water two foot nine inches; but the length of the pipe A, nine inches being deducted, the jet will only rise two foot. This, says Desaguliers, may be called a syphon *fountain*, where A B is the driving leg, and C D the rising leg.

FOUNTAIN *of Hero of Alexandria*, so called, because it was contrived by him. In the first *fountain* already described, the air is compressed by a syringe, in this, see *fig.* 35. the air, being only compressed by the concealed fall of water, makes a jet, which, after some continuance, is considered by the ignorant as a perpetual motion; because they imagine that the same water which fell from the jet rises again. The boxes C E and D Y X, being close, we see only the basin A B W, with a hole at W, into which the water spouting at B falls; but that water does not come up again; for it runs down through the pipe W X into the box D Y X, from whence it drives out the air, through the ascending pipe Y Z, into the cavity of the box C E, where, pressing upon the water that is in it, it forces it out through the spouting pipe O B, as long as there is any water in C E; so that this whole play is only whilst the water contained in C E, having spouted out, falls down through the pipe W X into the cavity D Y X. The force of the jet is proportional to the height of the pipe W X, or of the boxes C E and D Y above one another: the height of the water measured from the basin A B W to the surface of the water in the lower box D Y X, is always equal to the height measured from the top of the jet to the surface of the water in the middle cavity at C E. Now, since, the surface C E is always falling, and the water in D Y always rising, the height of the jet must continually decrease, till it is thrown up the height of the depth of the cavity C E, which, by supplying, added to the depth of the cavity D Y, which is always filling; and when the jet is fallen so low, it immediately ceases. The air is represented by the points in this figure. To prepare this *fountain* for playing, which should be done unobserved, pour in water at W, till the cavity D X Y is filled; then invert the *fountain*, and the water will run from the cavity D X Y into the cavity C E, which may be known to be full, when the water runs

runs out at B held down. Set the *fountain* up again, and, in order to make it play, pour in about a pint of water into the bason ABW; and, as soon as it has filled the pipe WX, it will begin to play, and continue as long as there is any water in CE. You may then pour back the water left in the bason ABW, into any veſſel, and invert the *fountain*, which being ſet upright again, will be made to play, by putting back the water poured out into ABW; and ſo on as often as you pleaſe.

The FOUNTAIN, *fig.* 36. is of the ſame kind; but, having double the number of pipes and concealed cavities, it plays as high again. In order to underſtand its ſtructure, ſee *fig.* 37. The baſon is A, the four cavities are B, C, D, and E, from which the water, through the pipe f G, ſpouts up to double the height of the *fountain*, the air at E, which drives it, being doubly condenſed. The water going down the pipe 1 (e. gr. three feet long), condenſes the air that goes up into the cavity C through the pipe 2, ſo as to make it $\frac{1}{3}$ ſtronger than the common air; then the water, which falling in the pipe 3 from C to D, is capable, by the height of its fall, of condenſing the air at E, ſo as to make it $\frac{1}{3}$ ſtronger, being puſhed at C by air already condenſed into $\frac{1}{3}$ leſs ſpace, cauſes the air at E to be condenſed twice as much; that is, to be $\frac{1}{3}$ ſtronger than common air; and, therefore, it will make the water at G ſpout out with twice the force, and riſe twice as high as it would do, if the *fountain* had been of the ſame ſtructure as the former. In playing this *fountain*, turn it upſide down, and taking out the plugs g, h, fill the two cavities C and E, and having ſtuck the holes again, ſet the *fountain* upright, and pour ſome water into the baſon A, and the jet will play out at G: but the *fountain* will begin to play ſoon; and, therefore, the beſt way is to have a cock in the pipe 2, which, being open, whilſt the cavities C and E are filled, and ſhut again before the *fountain* is ſet up, will keep the water thrown into the baſon from going down the pipe 1, and that of the cavity C from going down the pipe 3, by which means the *fountain* will not play before its time, which will be as ſoon as the cock is opened.

FOUNTAIN, *ſteel*, of *Deſaguliers*, is contrived to play by the ſpring of the air, increaſed by the heat of the ſun, and ſerves alſo for a dial at the ſame time. GNS, *fig.* 38. is a hollow globe of thin copper, eighteen inches in diameter, ſupported by a ſmall inverted baſon, reſting on a frame ABC, with four legs, between which there is a large baſon of two feet diameter. In the leg C there is a concealed pipe, proceeding from G, the bottom of the inſide of the globe, along HV, and joining an upright pipe u I, for making a jet at L. The ſhort pipe I u, going to the bottom of the baſon, has a valve at u under the horizontal part HV, and another valve at V above it, and under the cock, &c. At the north pole N, there is a ſcrew for opening a hole, through which the globe is ſupplied with water. When the globe is half filled, let the machine be ſet in a garden, and, as the ſun heats the copper and rarefies the included air, the air will preſs upon the water, which, deſcending through the pipe GCHV, will lift up the valve V, and ſhut the valve u, and, the cock being open, ſpout out at I, and continue to do ſo for a long time, if the ſun ſhines, and the ajutage be ſmall. At night, as the air condenſes again by the cold, the outward air, preſſing into the ajutage L, will ſhut the valve V, but by its preſſure on the baſon D o H, puſh up the water, which has been played in the day-time, through the valve u, and the pipe u H G into the globe, ſo as to fill it up again to the ſame height which it had at firſt, and the next ſun-ſhine will cauſe the *fountain* to play again, &c. The uſe of the cock is to keep the *fountain* from playing till you think proper: a ſmall jet will play ſix or eight hours. If the globe be ſet for the latitude of the place, and rectified before it be fixed, with the hour-lines or meridians drawn upon it, the hours marked, and the countries painted upon it, as in the common globe, it will be a good dial; the ſun ſhining upon the ſame places in this globe, as it does upon the earth itſelf. Deſaguliers, Exper. Phil. vol. ii. lect. 9. p. 205.

FOUNTAIN, with regard to *Architecture*, is an aſſemblage of maſonry, ſculpture, &c. either for the decoration or conveniency of a city, garden, or the like.

Fountains acquire various denominations, according to their form and ſituation: as,

FOUNTAIN, *arched*, that whoſe baſon and jet are placed perpendicularly under the arch. Such are the *fountains* of the Colonade, and the triumphal water-arch at Verſailles.

FOUNTAIN, *baſon*, is that with only a ſimple baſon, of any figure whatever; in the middle whereof is a jet, or ſpout, or perhaps a ſtatue, or even a group of figures. Such was formerly the *fountain* in the court of Buckingham-houſe.

FOUNTAIN, *covered*, a kind of pavilion, built of ſtone either inſulate, and ſquare, or round, or multilateral, or backed; and that either with a projecture, or indenture, including a reſervoir, and ſpouting or darting forth the water thereof through one or more cocks, in the middle of a ſtreet, ſquare, garden, court, or the like. Such was that in Lincoln's-inn new ſquare, London.

FOUNTAIN, *cup*, is that which, beſide a baſon, has likewiſe a cup of one ſingle piece of ſtone, or marble, ſupported on a ſhaft or pedeſtal, and receiving a jet, or ſpout, riſing out of the middle thereof.

As the *fountain* in the court of the Vatican is the cup whereof is of granite, and antique, being brought from the baths of Titus at Rome.

FOUNTAIN, *marine*, that compoſed of aquatic figures, as ſea divinities, tritons, tritons, rivers, dolphins, and other fiſhes, and ſhells. Such is the *fountain* of the palace of Paleſtrina at Rome, where a ſhell, ſupported by four dolphins, ſerves as a cup, and ſupports a triton, that ſpouts water out of his conch-ſhell.

FOUNTAIN, *moſs*, is that made in the form of a veſſel. Such is that of the place D'Eſpagne, at Paris, repreſenting a bark; that at Monte-Cavallo, repreſenting a galley; or that before the vineyard Mattei, at Rome, repreſenting a boat.

FOUNTAIN, *open*, is any ſpouting *fountain* with a baſon, cup, or other ornaments, all open; ſuch as are met with frequently in our gardens, and in the vineyards at Rome.

FOUNTAIN, *pyramidal*, that formed of ſeveral baſons, or cups, ranged in ſhorter over each other, and diminiſhing all the way, being ſupported by a hollow ſtem, or ſhaft. As the *fountain* of Monte-Dragone at *Frescati*.

Or elſe ſupported by figures, *ſiſtulæ*, or conſoles; the water whereof, in its fall, makes nets in theſe ſtories, and repreſents a kind of water-pyramid. As that at the head of the eſcalade at Verſailles.

FOUNTAIN, *rufſic*, is that formed, or encloſed, with rock-work, ſhell-work, petrifactions, &c.

FOUNTAIN, *ſatyric*, is a kind of ruſtic *fountain*, in the manner of a grotto, adorned with termini, mafcaroons, fauns, ſylvans, bacchantes, and other ſatyrical figures, ſerving for ornaments, as well as jets d'eau.

FOUNTAIN, *ſpouting*, or *jet d'eau*, is any *fountain*, whoſe water is darted forth impetuouſly through one or more jets, or ajutages, and returns in form of rains, nets, feſtoons, or the like. See JET *d'Eau*.

FOUNTAIN, *ſpring*, a kind of plain ſpout, or ſtream of water, iſſuing out of a ſtone, or hole in a wall, without any decoration. Such is the *fountain* of Trevi at Rome.

FOUNTAIN, *ſtatuary*, that which, being opened and inſulated, or even-backed, is adorned with one or more ſtatues, by way of finiſhing, or crowning. As the *fountain* of Latona, at Verſailles; and that at the Shepherd at Caprarola.

There are, alſo, ſtatues which ſpout forth water at ſome of their parts; or at ſea-ſhells, vaſes, urns, and other attributes of the ſea.

FOUNTAIN, *ſymbolical*, that where the principal ornaments are the attributes, arms, or cognizances, of the perſon who erected it. Such are the *fountain* of St. Peter in Montorio, reſembling a caſtle flanked with towers, and donjon, repreſenting the arms of Cardinal Cornaro; and ſome other *fountains* at Rome among which are the fleur-de-lis, and the dove, the bearings of the family of pope Innocent X.

FOUNTAIN-*pen*, is a ſort of pen contrived to contain a great quantity of ink, and let it flow, by gentle degrees, ſo as to ſupply the writer a long time without a neceſſity of taking freſh ink.

The *fountain*-pen, repreſented *Tab. Miſcellan. fig.* 15. conſiſts of divers pieces, F, G, H, of braſs, ſilver, &c. wherein the middle piece F carries the pen, which is ſcrewed into the inſide of a ſmall pipe; which, again, is ſoldered to another pipe of the ſame ſignels, as the lid G; in which lid is ſoldered a male ſcrew, for ſcrewing on the cover; as, alſo, for ſtopping a little hole at the place, and hindering the ink from paſſing through it: at the other end of the piece F is a little pipe, on the outſide whereof the top cover H may be ſcrewed. In the cover there goes a porte-craion, to be ſcrewed into the laſt mentioned pipe, in order to ſtop the end of the pipe into which the ink is to be poured by a funnel.

To uſe the pen, the cover G muſt be taken off, and the pen a little ſhaken, to make the ink run more freely.

FOUR-*corners*, in the *Manege*, or to work upon the *four-corners*, is to divide in imagination the volt or round into four quarters; ſo that, upon each of theſe quarters, the horſe makes a round or two at trot or gallop; and when he has done ſo much upon each quarter, he has made the *four-corners*.

FOUR, *œil de four*. See CUL.

FOURCHEE, or FOURCHY, in *Heraldry*. A croſs *fourchée* is that forked at the ends.

Upon rather repreſents it as anchored, the extremities turning

turning in a circular manner to sharp points; whereas the true cross *fourchee*, i. e. forked, has its forks composed of straight lines, and blunt ends. *See Tab. Herald. fig.* 33.

FOURCHER, an ancient law term, signifying a putting off, prolonging, or delaying, an action.

As by stammering we draw out our speech, not delivering that we have to say in ordinary times; so by *fourchin* we prolong a suit, that might be ended in a shotter space.

In Stat. Westm. 1. cap 42. we have these words: "Coparceners and joint-tenants shall be no more *fourch*, "but only shall have one essoin," &c. And anno 6 Edw. I. cap. 10. it is used in the same sense: "The defendants "shall be put to answer without *fourchin*," &c. In the Latin it is called *furcare*, and is used where a man and his wife do essoin severally. *Cumque vir & uxor implacitati, quod semper in essoniis alteritas observari, quamdiu* furcare *possint; & cum ultra non possint, concurrunt eorum essoniis in suis locis: alter autem eorum tantum unum essonium de malo lecti habere potest.* Hengham mag. cap. 9.

FOURCHETTE. *See de* FOURCHETTE. See FEN.

FOURMILLIER, in *Zoology*, the name given by Buffon to the *myrmecophaga didactyla* of Linnæus, or the little ant-eater; or lesser yellowish *tamandua*; or the white American *ouoti*. This animal has a comic nose bending a little downwards, ears that are small and hid in the fur, two hooked claws on the fore-feet, and four on the hind-feet; the head, body, limbs, and upper parts and sides of the tail, are covered with long, soft, silky hair, or rather wool, of a yellowish brown colour; the tail is thick at the bale, and tapers to a point. This species inhabits Guiana, and climbs trees in search of ants, which build their nests in the branches. *Tab.* II. *Quadrupedi*, N° 11. See ANT-*eater*.

FOURTH, in *Music*, one of the harmonic intervals, or concords.

The *fourth* is the fourth in order of the concords. It consists in the mixture of two sounds, which are in the ratio of 4 to 3; i. e. of sounds produced by chords, whose length are to each other as 4: 3.

It is called *fourth*, because containing *four* terms, or sounds, between its extremes, and three degrees; or, as being the *fourth*, in the order of the natural scale, from the fundamental.

The ancients call the *fourth* DIATESSARON, and speak of it as the first and principal of all concords; and yet the moderns find it one of the most imperfect. It is so very barren and jejune, that it affords nothing good, either by multiplication or division.

Some modern musicians have doubted whether the *fourth* should be received among the number of concords, or not. The ancients expressly admitted it as such, and Andreas Papius wrote a treatise against those moderns who reject it. Meisen. Harm. lib. iv. prop. 8. Wallis, Append. Ptolem. Harm. p. 182.

FOURTH, *diminished*, in *Music*. See DIMINISHED *fourth*.

The *redundant* FOURTH is a discord composed of the ratio of 27 to 20, and of 4 to 5.

Arches of the FOURTH *point*. See ARCH.

FOURTH *rate*. See RATE.

FOUTGELD, or FOOTGELD. See FOOTGELD.

FOWL, in a general sense, is of equal import with BIRD.

FOWL *is*, in a more peculiar manner, understood of poultry, or the larger sort of birds, both domestic and wild, either bred up, or hunted for the table.

Such as turkeys, geese, cocks, hens, and ducks both wild and tame, pheasants, partridges, pigeons, snipes, &c.

Our common poultry came originally from Persia and India. Aristophanes calls the cock the Persian bird, and that it was known in that country before Darius and Megabyzus; and these birds are now found wild in the isle of Timian, and other islands in the Indian ocean: in this state their plumage is black and yellow, and their combs and wattles purple and yellow. They have been naturalized in this country before the arrival of the Romans; for Cæsar informs us, that they were one of the forbidden foods of the old Britons. They were probably imported by the Phœnicians, who traded to Britain about five hundred years before Christ. For all other domestic *fowls*, turkies, geese, and ducks excepted, we seem to be indebted to our conquerors, the Romans. The wild *fowl* were our own from the earliest period. Pennant.

The belly of a living *fowl* being ript up, the creature is thus applied to a part bit by a rattle-snake, to draw out some of the poison. It seems to have some effect this way. We find an instance in the Philosophical Transactions, where a *fowl* thus applied to a hand bit by that most venomous snake, immediately swelled, grew black, and slunk. N° 479. p. 144.

The *sea-fowls* which come on shore in immense numbers to roost, in the north islands of Scotland, set their watches and centinels at distant posts, to give them notice of any danger; on the least alarm from these, the whole body rises, but without such notice they are not to be alarmed by almost any thing. The people of the country know this; and when they go out to take them, they employ all their art to take the centinels without noise; this they sometimes succeed in, and when they do, they often afterwards catch three hundred of the others, or more, in one night. Phil. Trans. N° 233.

The laying of these sea birds is less certain as to time than might be imagined. They can occasionally defer it; and as they usually lay in a rainy season, if the rain does not come on at the usual time, they will defer it some weeks; and if the April moon goes far in May, that also has been observed to hinder them from laying ten or twelve days longer than ordinary. See BIRD.

FOWL, *tame*, are a necessary part of the stock of a country farm; and yield considerable service and profit, by their EGGS, BROOD, FEATHERS, DUNG, &c.

They may be kept at a very easy expence near any high-way-side; as being able to shift for themselves, during the greatest part of the year, by their feeding on insects, worms, snails, and almost any thing eatable.

The eldest hens are always the best for sitting, and the youngest for laying; but no sort will be good for either, if kept too fat.

The best age to set a hen for CHICKENS, is, from two years old to five, and the most proper month to set them in, is February; though it may be done, to good purpose, at any time between that and Michaelmas. One cock will serve ten hens. A hen sits but twenty days; whereas geese, ducks, and turkeys, sit thirty.

Buckwheat, or French wheat, or hempseed, it is said, makes them lay faster than any other food; and the same buckwheat, either whole, or ground, and made into a paste, fats them apace; though the common food, for that purpose, is barley-meal, or pollard mixed up with hot water or milk. A goose will sooner sit on any but her own eggs; a hen will sit indifferently on all.

The lightest coloured geese are the best, and those that begin to lay the soonest; as they have a chance of hatching twice in one year. They begin to lay in the spring, and lay twelve or fifteen eggs. Green geese are begun to be fattened at a month old, and will be fat in a month more. Old geese are chiefly fattened at six months old, in or after the harvest. A wild goose, if red-footed and hairy, is old: but if white-footed, and not hairy, the is young.

When the eggs are set under a hen, or other *fowl*, it is advisable to mark the upper side thereof; and when the goes to feed, to note whether she minds to turn them upside down, or not; that if she neglect that office, it may be done for her.

FOWL, *water*, may be taken in great abundance by nets properly managed. The net for this purpose should be always made of the smallest and strongest packthread that can be got. The meshes may be large, but the nets should be lined on both sides with other smaller nets, every mesh of which is to be about an inch and a half square each way, that as the *fowl* strike either through them or against them, the smaller may pass through the great meshes, and so streighten and entangle the *fowl*.

These nets are to be pitched for every evening flight of *fowl*, about an hour before sun-set, staking them on each side of the river, about half a foot within the water, the lower side of the net being so plummed, that it may sink so far and no farther; place the upper side of the net flantwise, shoaling against the water, but not touching it by near two foot; and let the strings, which support this upper side of the net, be fastened to small yielding sticks fet in the bank: these as the *fowl* strike, will give the net liberty to play, and to entangle them. Several of these nets should be placed at once over different parts of the river, at about twelve-score fathom distance one from another: and if any *fowl* come that way, the sportsman will have a share of them. It is a good method, when the nets are set, to go to places sufficiently distant from them with a gun, to fright them toward the places where the nets are; and wherever any of the *fowl* are flutted from, it may not be amiss to plant some net also there, to take them as they return. The nets are to be left thus placed all night, and in the morning the sportsman is to go and see what is caught; he should visit the river first, and take up what are caught there, and, frightening the rest away to the other places where his nets are, be is next to visit them, and take what are there secured.

The Ceylonese have great plenty of water-*fowl* with in their islands, and have a very remarkable way of catching them, which is this: the fowler enters a lake or other water which has a good bottom, and is not very deep; he puts an earthen pot upon his head, in which there

are

are bored holes, through which he can *see*; he keeps himself so bent down in the water, that only the pot is above the surface; in this manner he enters the place where the wild-*fowl* are in cluſters, and they think it is only ſome floating block. He then takes ſome one by the legs, and gently draws it under water, and wrings its neck till he has killed it; then putting it into his bag, which is faſtened about his middle, he takes hold of another in the ſame manner, and ſo on, till he has got as many as he can carry off, and then he goes back in the ſame manner in which he came, not diſturbing the reſt of the birds, who never miſs their companions, but only ſuppoſe that they dive down for their diverſion, when the fowler pulls them under. In places where this has been practiſed ſo long or ſo carelefsly that the birds are ſhy, the fowler uſes a gun; but this he does in the following manner: he makes a ſcreen of about five foot high, and three foot wide, which he carries in one hand ſtraight between himſelf and his game, and in the other hand his gun. The birds are not alarmed at what appears only a buſh; for this ſcreen is always covered with branches of trees freſh cut down, and full of leaves, ſo that the ſportſman behind advances as near as he pleaſes, and then putting the gun through ſome crevice of the ſcreen, he fires. See DECOY: ſee an account of experiments on water-*fowl*, with regard to their faculty of reſpiration, under the article DUCK.

FOWL, *wild, driving of*. See DRIVING.

FOWLING, the act, or art, of catching birds with NETS, BIRDLIME, DECOYS, and other devices; as alſo of breeding up the ſame.

FOWLING is alſo uſed for the purſuing and taking of birds with hawks, falcons, and other birds of prey; more properly called FALCONRY and HAWKING.

FOWLING-*piece*, a portable fire-arm for the ſhooting of birds. Of *fowling*-pieces, thoſe are reputed the beſt, which have the longeſt barrel, viz. from 3½ feet to 6, with a moderate bore; though, for different occaſions, they ſhould be of different ſorts and ſizes: but in all, it is eſſential the barrel be well poliſhed, and ſmooth within, and the bore of an uniform bigneſs, from one end to another; which may be proved by thruſting in a piece of wood, cut exactly to the bore of the muzzle, down to the touch-hole; for if this goes down without ſtopping, you may conclude that the bore is good. The hedge pan ſhould be a little above the touch-hole, and ought to have a touch to let down a little powder, which will prevent the piece from recoiling. The locks ſhould be accurately filed, and their ſprings be neither too *ſtrong* nor too weak. The hammer ought to be well hardened, and pliable, ſo as to go down to the pan with a quick motion. In ſhooting, obſerve to do it with the wind, if poſſible, and rather ſide-ways, or behind the fowl, than full in their faces. Obſerve alſo to chuſe the moſt convenient ſhelter, as a hedge, bank, or tree. If you have not ſhelter enough, you muſt creep on your hand and knees, or uſe a ſtalking horſe. Let your dogs be under good command. See SETTING *Dog*, *Water* DOG, and SPANIEL.

FOX, *Vulpes*, in *Zoology*, an animal of the dog kind; much reſembling the common dog in form, and of the ſize of the ſpaniel. It is chiefly diſtinguiſhed by its long ſtraight tail, with a white tip to it. See CANIS and DOG.

It differs, however, from the common dog in the length, denſe diſpoſition, and ſoftneſs of the hairs, eſpecially thoſe about its tail, which is buſhy, much admired by the animal itſelf, and in cold weather wrapped round its noſe; and in its ſmell, which is peculiarly rank and diſagreeable. The ſmell of its urine is remarkably fœtid; inſomuch that the animal covers it in the earth. It is ſaid that the *fox* makes uſe of its urine as an expedient to force the cleanly badger from its habitation; however, it makes uſe of the badger's hole. Its uſual colour is a reddiſh tawney, though it is ſometimes found white, and ſometimes black. Its manner of digging itſelf a hole in the earth, is alſo a cuſtom wholly different from all the dog-kind; and it is far from the rameneſs of that animal, being with difficulty made to loſe its fierceneſs. Of all animals the *fox* has the moſt ſignificant eye, by which it expreſſes every paſſion of love, fear, hatred, &c. The *fox* is a crafty, lively, libidinous animal: it breeds only once in a year, unleſs ſome accident befalls its firſt litter, and brings four or five young, which, like puppies, are born blind.

The *fox* is a native of moſt northern countries, and there are three varieties of it, differing a little in form, but not in colour. They are diſtinguiſhed in Wales by different names. The greyhound *fox* is the largeſt, talleſt, and boldeſt, and will attack a grown ſheep or wether; the maſtiff *fox* is leſs, but more ſtrongly built; the cur *fox* is the leaſt, lurks about hedges, out-houſes, &c. and is the moſt pernicious to the feathered tribe. The firſt of theſe has a white tip to the tail; the laſt a black. The ſkin of this animal is furniſhed with a ſoft and warm fur, which in many parts of Europe is uſed to make muffs and fine cloaks.

A *fox* in the firſt year is called a cub; in the ſecond, a *fox*, and afterward an old *fox*. It is a beaſt of chaſe, uſually very prejudicial to the huſbandman, by taking away and deſtroying his lambs, geeſe, and poultry. It will feed on fleſh of any kind; and when urged by hunger eat carrots and inſects; and, near the ſea-coaſt, for want of other food, eat crabs, ſhrimps, or ſhell-fiſh. In France and Italy it does incredible damage in the vineyards, by eating the grapes, of which it is very fond. The *fox* is a great deſtroyer of rats, and ſuch animals. It ſecures its booty by digging holes in ſeveral places; and if a whole flock of poultry ſhould happen to be its prey, will bring them one by one, thruſt them in with its noſe, and conceal them by ramming the looſe earth upon them, till the calls of hunger induce him to devour them. The common way to catch him is by guns, which being baited, and a train made by drawing raw fleſh across his uſual paths or haunts to the gin, it proves an inducement to lure him to the place of deſtruction. They are alſo taken with greyhounds, hounds, terriers, and nets: it is a commendable exerciſe to hunt theſe miſchievous beaſts, the nature of which in many reſpects is like that of wolves. See HUNTING.

FOX, *fiſh*. See ALOPIAS.

FOX, *Silurian*. See LAGOCEPH.

FOX, *fox, vulpes marina*, in *Ichthyology*, the name given by authors to a large fiſh, called the *ſea-fox* by us. In the Artedian ſyſtem it is the SQUALUS, with a tail longer than the body. It is ſaid by many authors to have naturally the rank ſmell of the *fox*, and to be one of the moſt-taſted fiſhes; but this does not appear to be true, on ſtrict enquiry; for its ſmell ſeems very little different from that of other fiſhes, and its fleſh is well-taſted; ſo that theſe things ſeem only to have been ſaid, in order to ſtrengthen the reſemblance with the *fox*; a name which ſeems, upon the whole, to have been given it only from the length of its tail; and even that, though very long for a fiſh of this kind, has no reſemblance with the tail of a fox. The length of this fiſh is about nine feet, ſometimes twelve or thirteen, and its breadth, in the broadeſt part of the belly, fourteen inches. Its tail is nearly as long as the whole body beſide, and is of the ſhape of a ſcythe, and is bent downwards. Near the origin of the tail, it has a ſingle fin below, and the ſpine is more moveable up and down in this part, than in any other; ſo that the tail is, by this means, eaſily elevated or depreſſed. It has two eminences on the back, a large one near the middle, and a ſmall one near the tail. It has three fins on each ſide; the pair near the head are large, and reſemble the wings of a bird; the others are ſmaller. The ſkin is ſmooth, and without ſcales; and the fins and eminences on the back are compoſed of a ſort of fibs, held together by a tough and ſtrong membrane. The tongue adheres inſeparably to the lower jaw, and is compoſed of a great number of bones, articulated together by a fleſhy ſubſtance of a fibrous texture, and covered with a membrane, in which there are ſeveral prominences, which, when viewed with the microſcope, appears as pelluced as the fineſt cryſtal. Its throat and ſtomach are remarkably large; and authors ſay, that when in a fright it will ſwallow its young ones into its ſtomach, and afterwards caſt them up again when the danger is over. Others, who ſpeak largely of its cunning, ſay, that when it has ſwallowed a bait at a hook, it will take in the whole line, till it comes to a weak place, where it can bite it aſunder. This is a tale very well calculated for the carrying on a reſemblance with the *fox* in cunning; but it is very ill adapted to this fiſh, which has no teeth with which it can bite any thing aſunder. The heart of this fiſh is remarkably ſmall, nothing larger than a hen's egg: it is alſo much of the ſame ſhape, and has no pericardium; but the aorta for a little way is covered with a membrane analogous to a pericardium. The head ſeems a mere lump of fleſh, being covered with muſcles, of which ſome are four inches thick; and though the head is ſo large, the ſkull is not bigger than a man's ſiſt; it is thick, and is divided within into three cavities, each of which contains a ſmall quantity of a mucous matter mixed with blood; ſo that the fiſh ſeems ſcarce to have any brain at all, what little matter of it there is being quite ſoft, and having very few windings. The eyes are as large as thoſe of an ox, and are only hemiſpheric in figure, being flat before, ſo that they appear of a very ſingular ſhape. Mem. pour Hiſt. Anim. p. 114.

The teeth are triangular, ſmall, and placed in three rows; the back is aſh colour, and the belly white. The guts of this fiſh have a very peculiar ſtructure. In the upper part of them, inſtead of the ordinary circumvolutions of the guts of animals, the cavity is diſtinguiſhed by many tranſverſe ſeparations, compoſed of the membranes of the inteſtine turned inwards; theſe ſepa-

tations ſtand at about half an inch diſtance from one another, and turn helically like a ſnail-ſhell. The conſequence of this is, that the food is detained a long time in its paſſage, though the way it has to go be very ſhort. This creature feeds both on other fiſh, and on ſea-plants. Ouvrage adopté de l'Acad. Par. vol. i.

This fiſh has been ſometimes taken in *our ſeas*, and imagined to be the fiſh called the threſher, from its attacking and beating the grampus with its long tail, when it riſes to the ſurface to breathe.

FOX, in *Sea Language*, ſignifies a ſort of ſtrand, formed by twiſting ſeveral rope-yarns together, and uſed as a ſeizing, or to weave a mat or paunch, &c.

FOX-*glove*, *Digitalis*, in *Botany*, a genus of the *didynamia angioſpermia* claſs. Its characters are theſe: the flower is bell-ſhaped, of one petal, with a large open tube, whoſe brim is ſlightly divided into five parts; it has four ſtamina, which are inſerted in the baſe of the petal; two being longer than the other; the germen afterward ſwells to an oval capſule, having two cells including many ſmall angular ſeeds. Linnæus enumerates ſix and Miller nine ſpecies, which are great ornaments to a garden.

All theſe ſorts ſhould be ſown in autumn; for if the ſeeds are ſown in the ſpring, they commonly fail, or at leaſt lie a whole year in the ground before they begin to vegetate. The plants, one ſpecies excepted, are biennial, and periſh as ſoon as the ſeeds are ripe. Miller.

The common *fox-glove*, or the purple *fox-glove*, with a rough leaf, grows wild in woods, and on heaths; flowers in June, and the ſeeds ripen in autumn. The leaves commanigate a bitteriſh and mucilaginous taſte both to watery and ſpirituous menſtrua; and have been ſtrongly recommended in epileptic diſorders. It operates by ſtool and vomit; but with ſuch violence, that it is now diſuſed. Boerhaave judges it to be of a poiſonous nature; Dr. Alſton, on the contrary, ranks it among thoſe indigenous vegetables, which, though now diſregarded, are medicines of great virtue, and ſcarcely inferior to any that the Indies afford. Externally, the leaves and flowers have been employed with great ſafety, and with ſucceſs, in cataplaſms and unguents for ill-conditioned ulcers. The *unguentum digitale* takes its name from this plant. Lewis's Mat. Med.

FOX-*tail graſs*. See GRASS.

FOYLING *of land*, among *Farmers*, the FALLOWING it in ſummer and autumn.

FOYLING, among *Sportſmen*, a term uſed for the footſteps of a hare, on the graſs or leaves.

FOYNA, in *Zoology*, a name given by many to the MARTIN or *martel*, an animal of the weaſel-kind, common with us.

FRACHES, in the *Glaſs-Trade*, are the flat iron pans into which the glaſs veſſels already formed are put, when in the tower over the working furnace, and by means of which they are drawn out through the leers, that they may be taken gradually from the fire, and cool by degrees.

FRACTION, in *Arithmetic* and *Algebra*, a part or diviſion of an unit, or integer; or, a number which ſtands to an unit in the relation of a part to its whole.

The word literally imports a broken number.

Fractions are uſually divided into *decimal*, *ſexageſimal*, and *vulgar*.

For *decimal*, *and ſexageſimal fractions*, ſee DECIMAL, and SEXAGESIMAL.

FRACTIONS, *Vulgar*, called alſo ſimply, *fractions*, are always expreſſed by two numbers, the one wrote over the other, with a line between them.

The lower, called the *denominator of the fraction*, denotes the unit, or whole, that is divided into parts; and the upper, called the *numerator of the fraction*, expreſſes the parts given in the preſent caſe.

Thus, two-third parts of a line, or other thing, are wrote $\frac{2}{3}$; where the denominator 3 ſhews that the whole line is ſuppoſed to be divided into three equal parts; and the numerator 2 indicates or aſſigns two of ſuch parts.

Again, twenty-nine ſixtieths is wrote $\frac{29}{60}$; where the numerator 29 expreſſes 29 parts of an integer divided into 60; and the denominator 60 gives the denomination to theſe parts, which are called *ſixtieths*.

The real deſign of adding the denominator is, to ſhew what aliquot part the broken number has in common with unity.

In all *fractions*, as the numerator is to the denominator, ſo is the *fraction* itſelf to the whole whereof it is a *fraction*.

Thus, ſuppoſing $\frac{1}{4}$ of a pound equal to 15*s*. it is evident, that 3 : 4 :: 15 : 20. Whence it follows, 1°, That there may be infinite *fractions* of the ſame value, one with another; inaſmuch as there may be infinite numbers found, which ſhall have the ratio of 3 : 4.

Fractions are either *proper*, or *improper*.

FRACTION, *Proper*, is that where the numerator is leſs than the denominator; and, conſequently the *fraction* leſs than the whole, or integer, as $\frac{2}{3}$.

FRACTION, *Improper*, is where the numerator is either equal to, or bigger than the denominator, and of courſe the *fraction* equal to, or greater than the whole, or integer, as $\frac{3}{3}$ or $\frac{5}{4}$, or $\frac{7}{5}$.

Fractions, again, are either *ſimple*, or *compound*.

FRACTIONS, *Simple*, are ſuch, as conſiſt of only one numerator, and one denominator; as $\frac{3}{5}$, or $\frac{2}{3}$, &c.

FRACTIONS, *Compound*, called alſo *fractions of fractions*, are ſuch as conſiſt of ſeveral numerators, and denominators; as $\frac{2}{3}$ of $\frac{3}{4}$ of $\frac{4}{5}$, &c.

Of *fractions*, thoſe are equal to each other, whoſe numerators have the ſame ratio to their denominators.—Thoſe are greater, whoſe numerators have a greater ratio; and thoſe leſs which have leſs: thus, $\frac{1}{2}=\frac{2}{4}=\frac{3}{6}=\frac{4}{8}$. But $\frac{2}{3}$ is greater than $\frac{3}{5}$; and $\frac{3}{5}$ leſs than $\frac{2}{3}$. Hence if both the numerator, and denominator of a *fraction*, as $\frac{2}{3}$, be multiplied or divided by the ſame number, 2; the facts in the former caſe, $\frac{4}{6}$, and the quotients in the latter $\frac{1}{3}$, will conſtitute *fractions* equal to the firſt *fraction* given.

The arithmetic of *fractions* conſiſts in the *reduction*, *addition*, *ſubtraction*, and *multiplication* thereof.

FRACTIONS, *reduction of*. 1. *To reduce a given whole number into a* fraction *of any given denominator*. Multiply the given integer, by the given denominator, the factum will be the numerator. Thus we ſhall find $3=\frac{6}{2}$ and $5=\frac{15}{3}$; and $7=\frac{14}{2}$, &c.

If no denominator be given, the number is reduced to a *fraction*, by writing 1 underneath it, as a denominator. Thus $\frac{3}{1}$, $\frac{7}{1}$, &c.

2. *To reduce a given fraction to a fraction equal to it, that ſhall have a given denominator*. Multiply the numerator by the given denominator, and divide the product by the former denominator, and the quotient ſet over the given denominator is the *fraction* required. Let it be propoſed to reduce $\frac{3}{8}$ to an equal *fraction* with the denominator 8; $8\times3\div4=6$ and $\frac{6}{8}=\frac{3}{4}$.

3. *To reduce a given* fraction *to its loweſt terms*; i. e. to find a *fraction*, equivalent to a given *fraction* ($\frac{24}{48}$), but expreſſed in leſs numbers: divide both the numerator 24, and denominator 48, by ſome one number, that will divide them both without any remainder, as here by 4. The quotients 6 and 12 make a new *fraction* $\frac{6}{12}$ equal to $\frac{24}{48}$.

And if the diviſion be performed with the greateſt number that will divide them both, the *fraction* is reduced to its loweſt terms. *See* COMMON *Meaſure*.

If it happens that unity is the only common meaſure of the numerator and denominator; then is the *fraction* incapable of being reduced any lower: and numbers whoſe greateſt common meaſure is unit, are ſaid to be PRIME to each other.

4. *To reduce two or more* fractions *to the ſame denomination*; i. e. to find *fractions* equal to the given ones, and with the ſame denominator. Multiply each numerator, ſeparately taken, into all the denominators but its own, and the products ſhall give the new numerators. Then multiply all the denominators into one another, and the product will be the common denominator. Thus, $\frac{2}{3}$ and $\frac{4}{5}$ are $\frac{10}{15}$ and $\frac{12}{15}$; and $\frac{2}{3}$, $\frac{4}{5}$ and $\frac{5}{7}$ are reſpectively $\frac{70}{105}$, $\frac{84}{105}$, and $\frac{75}{105}$.

5. *To find the value of a* fraction, *in the known parts of its integer*. Suppoſe, e. gr. it were required to know what is $\frac{3}{5}$ of a pound; multiply the numerator 3 by 20, the number of known parts in a pound, and divide the product by the denominator 10, the quotient gives 12*s*. Then multiply the remainder 4 by 12, the number of known parts in the next inferior denomination; and dividing the product by 16, as before, the quotient is 3*d*. So that $\frac{3}{5}$ of a pound=12*s*. 3*d*.

6. *To reduce a mixed number*, i. e. *a number partly integral and partly fractional*, as $4\frac{3}{4}$ *into an improper* fraction *of the ſame value*. Multiply the integer, 4, by 12, the denominator of the *fraction*; and to the product 48 add the numerator 3 the ſum 51 ſet over the former denominator, $\frac{51}{12}$, conſtitutes the *fraction*.

7. *To reduce an improper* fraction *into its equivalent mixed number*. Suppoſe the given *fraction* $\frac{51}{12}$; divide the numerator by the denominator; the quotient is the integral part, and the remainder ſet over the denominator will be the fractional part. Thus, $\frac{51}{12}=4\frac{3}{12}$.

8. *To reduce a compound* fraction *into a ſimple one*. Multiply all the numerators into each other for a new numerator; and all the denominators for a new denominator. Thus $\frac{2}{3}$ of $\frac{3}{4}$ of $\frac{4}{5}$ reduced will be $\frac{24}{60}$.

9. *To reduce a vulgar* fraction *to a decimal of the ſame value*. See DECIMAL.

FRACTIONS, *addition of vulgar*. 1. If the given *fractions* have different denominators, *reduce* them to the ſame. Then add the numerators together, and under the ſum write

write the common denominator. Thus, e. gr. $\frac{1}{2}+\frac{1}{3}=1\frac{1}{2}=1\frac{3}{6}=1\frac{4}{6}$.

2. If compound *fractions* are given to be added, they muſt firſt be reduced to ſimple ones: and if the *fractions* be of different denominations, as $\frac{1}{2}$ of a pound, and $\frac{1}{3}$ of a ſhilling, they muſt firſt be reduced to *fractions* of the ſame denomination of pounds.

3. *To add mixt numbers.* The integers are firſt to be added, then the fractional parts: and if the ſum be a proper *fraction*, only annex it to the ſum of the integers. If it be an improper *fraction*, reduce it to a mixed number, adding the integral parts thereof to the ſum of the integers, and the fractional part after it. Thus, $5\frac{1}{2}+4\frac{1}{2}=10\frac{2}{2}$.

FRACTIONS, *ſubtraction of*. 1. If they have the ſame common denominator, ſubtract the leſſer numerator from the greater, and ſet the remainder over the common denominator. Thus from $\frac{3}{4}$ take $\frac{1}{4}$, and there remains $\frac{2}{4}=\frac{1}{2}$.

2. If they have not a common denominator, they muſt be reduced to *fractions* of the ſame value, having a common denominator, and then, as in the firſt rule. Thus, $\frac{2}{3}-\frac{1}{2}=\frac{4}{6}-\frac{3}{6}=\frac{1}{6}$.

3. *To ſubtract a whole number from a mixed number, or one mixed number from another.* Reduce the whole, or mixed numbers to improper *fractions*, and then proceed as in the firſt and ſecond rule.

FRACTIONS, *multiplication of*. 1. If the *fractions* propoſed be both ſimple, multiply the numerators one by another for a new numerator, and the denominators for a new denominator. Thus $\frac{1}{2}$ into $\frac{1}{2}$ produces $\frac{1}{4}$.

2. If one of them be a mixed, or whole number, it muſt be reduced to an improper *fraction*; and then proceed as in the laſt rule. Thus $\frac{1}{2}$ into $5\frac{1}{2}$, gives $\frac{11}{4}$, and $\frac{2}{5}$ into $10=\frac{20}{5}$.

In multiplication of *fractions*, obſerve that the product is leſs in value, than either the multiplicand, or multiplicator; becauſe in all multiplications, as unity is to the multiplicator, ſo is the multiplicand, to the product; or, as unity is to either factor, ſo is the other factor, to the product. But unity is bigger than either factor, if the *fractions* be proper; and therefore either of them muſt be greater than the product.

Thus, in whole numbers, if 5 be multiplied by 8, it will be as $1:5::8:40$; or $1:8::5:40$. Wherefore in *fractions*, alſo, as $1:\frac{1}{2}::\frac{1}{2}:\frac{1}{4}$; or as $1:\frac{1}{2}::\frac{1}{2}:\frac{1}{4}$. But 1 is greater than either $\frac{1}{2}$, or $\frac{1}{2}$; wherefore either of them muſt be bigger than $\frac{1}{4}$.

FRACTIONS, *diviſion of*. 1. If the *fractions* propoſed be both ſimple, multiply the denominator of the diviſor by the numerator of the dividend: the product is the numerator of the quotient: then multiply the numerator of the diviſor by the denominator of the dividend, the product is the denominator of the quotient. Thus $\frac{1}{2}\div\frac{1}{3}=\frac{3}{2}$. Or, invert the diviſor and proceed as in multiplication.

2. If either dividend, diviſor, or both, be whole, or mixed, numbers, reduce them to improper *fractions*; and if they be compound *fractions*, reduce them to ſimple ones, and proceed as in the firſt rule.

In diviſion of *fractions* obſerve, that the quotient is always greater than the dividend; becauſe in all diviſion, as the diviſor is to unity, ſo is the dividend to the quotient: as if 3 divide 12, it will be, as $3:1::12:4$. Now 3 is greater than 1, wherefore 12 muſt be greater than 4: but in *fractions*, as $\frac{3}{4}:1::\frac{1}{2}:\frac{1}{6}$; where, $\frac{1}{2}$ is leſs than 1; wherefore $\frac{1}{6}$ muſt alſo be leſs than $\frac{1}{2}$.

FRACTIONS *in ſpecies*, or *algebraic quantities*. 1. *To reduce fractions in ſpecies to their leaſt terms.* The numerators and denominators are to be divided by the greateſt common diviſor, as in numbers.

Thus the *fraction* $\frac{aac}{bc}$ is reduced to a more ſimple one $\frac{aa}{b}$ by dividing both aac, and abc, by c: and $\frac{203}{667}$ is reduced to a more ſimple one $\frac{7}{23}$ by dividing both 203 and 667 by 29: and $\frac{203aac}{667bc}$ is reduced to $\frac{7aa}{23b}$ by dividing by $29c$. And ſo $\frac{6aa-9ac}{6aa+3ac}$ becomes $\frac{2a-3c}{2a+c}$ by dividing by $3a$. And $\frac{a^3-aab+abb-b^3}{aa-ab}$ becomes $\frac{aa+bb}{a}$ by dividing by $a-b$. See COMMON *Meaſure*.

2. *To reduce fractions in ſpecies to a common denominator.* The terms of each are to be multiplied by the denominator of the other.

Thus, having $\frac{a}{b}$ and $\frac{c}{d}$; multiply the terms of one $\frac{a}{b}$ by d, and alſo the terms of the other $\frac{c}{d}$ by b, and they will become $\frac{ad}{bd}$ and $\frac{bc}{bd}$ whereof the common denominator is bd. And thus a and $\frac{ab}{c}$, or $\frac{a}{1}$ and $\frac{ab}{c}$, become $\frac{ac}{c}$ and $\frac{ab}{c}$.

But where the denominators have a common diviſor, it is ſufficient to multiply them alternately by the quotients.

Thus the *fraction* $\frac{a^2}{bc}$ and $\frac{ab}{bd}$ are reduced to theſe $\frac{a^2d}{bcd}$ and $\frac{abc}{bcd}$ by multiplying alternately by the quotients c and d, ariſing by the diviſion of the denominators by the common diviſor b. The other operations, with reſpect to numbers, are eaſily applied to algebraic quantities.

Addition and ſubtraction of fractions *in ſpecies*. The proceſs is, in all reſpects, the ſame in ſpecies as in numbers. E. gr.

Suppoſe it be required to add the *fractions* $\frac{a}{b}$ and $\frac{c}{d}$. Theſe, when reduced to the ſame denomination, will be $\frac{ad}{bd}$ and $\frac{bc}{bd}$; conſequently their ſum is $\frac{ad+bc}{bd}$.

So, if the *fraction* $\frac{a}{b}$ were to be ſubtracted from $\frac{c}{d}$; having reduced them they will be $\frac{ad}{bd}$ and $\frac{bc}{bd}$, as before.

Their difference, therefore, is $\frac{bc-ad}{bd}$.

Multiplication and diviſion of fractions *in ſpecies*. Here, too, the proceſs is perfectly the ſame as in vulgar arithmetic. Thus, e. gr. ſuppoſe the factors, or *fractions* to be multiplied, $\frac{a}{b}$ and $\frac{c}{d}$: the product will be, $\frac{ac}{bd}$.

Or ſuppoſe the *fractions*, required to be divided, $\frac{ac}{bd}$ and $\frac{a}{b}$; the quotient will be, $\frac{ac}{bd}\times\frac{b}{a}=\frac{abc}{abd}=\frac{c}{d}$.

Hence, as $a=\frac{a}{1}$; the product of a into $\frac{c}{d}$, that is, of an integral quantity into a *fraction*, $\frac{c}{d}\times\frac{a}{1}=\frac{ac}{d}$. Whence it appears, that the numerator of the *fraction* is to be multiplied by the integer.

Hence, alſo, the quotient of $\frac{c}{d}$ by a, that is, of the broken quantity, divided by the whole one, $\frac{c}{d}\times\frac{1}{a}=\frac{c}{ad}$.

Beſide the common notion of a *fraction*, there is another neceſſary to be underſtood. Thus, Suppoſe $\frac{1}{2}$ of 20*s*. or a pound ſterling, were the *fraction*: this *fraction*, inſtead of three quarters of one pound, may be conſidered as a fourth part of three pounds; that is, by taking as many of the integers as the numerator expreſſes (viz. 3), and dividing them by 4, the denominator, for then the quotient of the ſame value will ariſe; for $4)60s.(15s.$ This ſhews the reaſon of that manner of expreſſion uſed by geometers and algebraiſts, who read $\frac{a}{b}$, thus, a divided by b.

FRACTION, *continued*, is uſed for a *fraction* the denominator of which is a whole number with a *fraction*, the denominator of which is again a whole number and a *fraction*, and ſo on, whether this affection be continued *ad infinitum*, or whether the ſeries breaks off after a finite number of terms. Thus,

$$\text{or } \frac{1}{2+\frac{2}{3+\frac{3}{4+\frac{4}{5+}}}}, \text{ &c.}$$

$$\frac{1}{2+\frac{1}{3+\frac{1}{4+\frac{1}{5+}}}}, \text{ &c.}$$

are *continued fractions*.

If we make uſe of letters inſtead of numbers, we ſhall have general expreſſions of theſe *fractions*, thus,

$$a+\frac{1}{b+\frac{1}{c+\frac{1}{d+\frac{1}{e+\frac{1}{f+}}}}}, \text{ &c.}$$

and

$$a+\frac{\alpha}{b+\frac{\beta}{c+\frac{\gamma}{d+\frac{\delta}{e+\frac{\varepsilon}{f+}}}}}, \text{ &c.}$$

The reduction of theſe *continued fractions* to thoſe of a common form, is not difficult by the uſual rules of arithmetic

arithmetic and algebra. Thus, to give an example which may at the same time shew the use of these *continued fractions*; suppose the *continued fraction*,

$$3+\frac{1}{7+\frac{1}{15+\frac{1}{1+\frac{1}{292+\frac{1}{1+\frac{1}{1+}}}}}}, \text{ \&c.}$$

which expresses the circumference of a circle, when the diameter is one; if we stop at $\frac{1}{7}$, we shall have $3+\frac{1}{7}=\frac{21+1}{7}=\frac{22}{7}$. If we stop at $\frac{1}{15}$, we shall have

$$3+\frac{1}{7+\frac{1}{15}}=3+\frac{1}{\frac{106}{15}}=3+\frac{15}{106}=\frac{318+15}{106}=\frac{333}{106}$$

But if we stop at $\frac{1}{1}$, which is convenient on account of the small *fraction* $\frac{1}{292}$, added to the last denominator 15, we shall then find, $3+\frac{1}{7+\frac{1}{15+\frac{1}{1}}}=\frac{355}{113}$. The first of the reductions gives the proportion of Archimedes, and the last that of Adrian Metius.

But as beginning at the last denominator of the *continued fraction* makes the computation somewhat tedious, shorter methods have been contrived for the reduction of these *fractions*, and for a continued approximation to their true value. And Mr. Cotes's method for the reduction of ratios to smaller terms, may be here applied. (See RATIO.) For it is to be observed, that when the numerators of the *continued fraction* are each units, the denominators will be the quotients arising from the continued divisions in Mr. Cotes's method: or in the common, for reducing *fractions* to a lower denomination, which is in effect the same as Euclid's method for finding the greatest common measure of two magnitudes, lib x. prop. 3. But a detail of these things would lead us too far, we therefore refer the reader for a further account of these *continued fractions* to Dr. Wallis's Arithmet. infinit. prop. 191. Oper. vol. i. p. 469, seq. Huygens, Descript. Automat. Planetar. in Oper. posthum. p. 173, seq. edit. Amstelod. 1728. and particularly to Mr. Euler's Analys. Infinit. vol. i. cap. xviii. p. 295, seq. who has shewn the use and application of this doctrine in many instances.

Lord Brouncker seems to have been the first who considered *continued fractions*, or at least who first applied them to the quadrature of curves. The hint seems useful, but has been pretty much neglected, excepting in approximations to *fractions* or ratios expressed in great numbers. See the article RATIO. His series for the quadrature of the circle, is

$$\square=1-\frac{1^2}{2-}\frac{2^2}{2-}\frac{3^2}{2-}\frac{4^2}{2-}\frac{5^2}{2-}\frac{6^2}{2-}\frac{7^2}{2-}, \text{ \&c.}$$

In his and Dr. Wallis's notation, which amounts to the same thing as $1+\frac{1}{2+}\frac{2}{2+}\frac{2}{2+}$, \&c.

in the notation of Huygens and Euler.

The symbol $\square$ denotes, as before, the ratio of the square of the diameter to the area of the circle.

FRACTION *expressed of a decimal*. See REPETEND.

FRACTION, *logarithm of a*. See LOGARITHM.

FRACTIONS, *summing of infinite*. See CALCULUS and FLUXIONS.

FRACTURE, in *Medicine* and *Surgery*, a breach, or rupture, of a bone; or a solution of continuity in a bone, when it is crushed, or broken, by some external cause.

This may be discovered by the eye, when the injured part is apparently shorter than the sound one, or when the patient cannot make use of it; by the touch, when a preternatural inequality of the bone may be perceived, or where it bends in a part where nature did not design it should; or by the ear, when, upon moving of the limb, the grating of the broken bones may be heard.

Fractures may be distinguished into several classes or species. First, every *fracture* is either *simple*, that is, when no other parts beside the bone are injured; or *compound*, that is, when you have at the same time a wound, a dislocation, haemorrhage, inflammation, fever, caries or contusion of the bone; or where the bone is fractured in several places at the same time. Other differences arise with regard to the situation of the *fractures*, and from its position: some are transverse, others longitudinal, called FISSURES, and others oblique; in which case it frequently happens, that the points of the bones wound or push themselves through the neighbouring parts. Violent CONTUSIONS also may be classed under the head of *fractures*; for in these the bones are frequently broken into splinters, by the falling of any heavy body upon the part, or other such accidents. When the situation of the bone is not altered by a *fracture*, or the broken parts start very little from their proper situation, they are much easier replaced than when they are entirely separated from one another, and a great space intervenes between them. Transverse *fractures* admit of an easier cure than oblique ones. A *fracture* in the middle of a bone is less dangerous than one towards the articulation. When two bones of the same limb are fractured, the cure is usually much more difficult than when only one is fractured. When the bone is broken into several pieces, the patient seldom escapes a gangrene, at least the cure in these cases requires a longer time, and the limb seldom recovers its true shape.

When the broken bones are instantly reduced, the cure will be much sooner performed, than when they have been some time separated. *Fractures* in the neighbourhood of parts of great consequence to the animal oeconomy, are always attended with great danger, such as *fractures* of the cranium from the vicinity of the brain; of the vertebræ, from the medulla spinalis; and of the ribs or sternum, or the ossa ilei and pubis, from the situation of the viscera of the thorax and abdomen. *Fractures* of the bones to which the larger arteries are connected, are also very dangerous; more particularly, when one splinter or point of the bone wounds one of these large vessels, or when the bone is broken into several fragments, the consequences are generally inflammations, suppurations, or fistulæ, which will admit of no remedy, till the splinter of the bone is removed. *Fractures* proceeding from internal disorders or caries of the bones, as such sometimes happen, are cured with much more difficulty than those arising from external injuries; nay this indeed is frequently an incurable case unless the internal cause be first removed. This is usually either a scorbutic habit of body, or a venereal taint. When a large piece of the bone is driven away by a pistol or musket-ball, the limb must be taken off, for the two ends of the bone are never likely to unite, unless it be a very small piece that is thus taken away; for in that case the bone will sometimes join, but then the limb always becomes something shorter than it was before. When the blood insinuates itself by a fissure into the internal part of the bone, by corrupting there it produces a caries, a spina ventosa, or else incurable fistulæ, tabes, and a sphacelus, which always require amputation of the limb, and frequently destroy the patient. The same accidents will happen in *fractures* of any kind, when the extravasated blood mixes with the marrow and corrodes it. Heister's Surg. p. 103.

Instances have been known of the *fracture* of the patella in persons thoroughly sound, where the part itself has received no hurt. The cause of this is ascribed to the action of the muscles only. And many instances might be given of *fractures* in the neck of the os femoris, in the middle of the humerus, tibia, and perone, by the power of the muscles only, or such power at least as shewed they have as great a share in several *fractures* ascribed to outward causes, as they are frequently known to have in the *fracture* of the tendo Achillis. We have an observation of a *fracture* of the os humeri, by the power of the muscles only, in the Philosophical Transactions, N° 475. sect. 15.

In the cure of *fractures* the surgeon has two things to attend to: firstly, to restore the fractured bone into its natural situation; and then, to keep it strait and easy with fetules or splinters, and bandages, which should by no means be tight: in which case, nature takes on herself the office of healing and conglutinating it, by forming a callus upon it.

The best method of retention is by two or more splints made of leather or pasteboard. These, if moistened before they be applied, soon assume the shape of the included member, and are sufficient, with the assistance of a very slight bandage, for all the purposes of retention. The belt BANDAGE is that made with twelve or eighteen tails: this is much easier applied and taken off than rollers, and answers all the purposes of retention equally well: the splints should always be as long as the limb, with holes cut for the ankles when the *fracture* is in the leg. In *fractures* of the ribs, where a bandage cannot properly be used, an adhesive plaster may be applied over the part. The most proper external application for a *fracture* is oxycrate, or a mixture of vinegar and water; with which the bandages should be moistened at every dressing.

If there be an inflammation, it must be cured before any thing be attempted about the *fracture*: if the bone happen to be broken again, it never breaks in the callus, but at a distance from it. After setting, or replacing, the

fractured bone, the bleeding is required, to prevent any lodgment of blood on the part aggrieved, by the violence upon the fibres.

With regard to the regimen and general treatment of the patient in these circumstances, we may observe, that, when a large bone is broken, his diet should in all respects be the same as in an inflammatory fever: he should likewise be kept quiet and cool, and his body open by emollient clysters, or by food of an opening quality. However, persons that have been accustomed to high living should not be suddenly reduced to a low diet. It will generally be necessary to bleed the patient immediately after a *fracture*, especially if he be young, of a full habit, and has received any contusion: and if the patient be very feverish, bleeding may be repeated the next day. In *fractures* of the ribs, bleeding is peculiarly necessary; when any of the large bones, by which the body is supported, are broken, the patient should keep his bed for several weeks; reclining in an easy posture. When a *fracture* is accompanied with a wound, it must be dressed in all respects as a common wound. When the fractured bone is much shattered, it will sometimes be necessary to have the limb taken off, lest a gangrene or mortification ensue.

FRACTURE *of the carpus*, or *wrist*, *clavicle*, *cubit*, *finger*, *foot*, *humerus*, *jaw*, *leg*, *metacarpus*, *neck*, *nose*, or *innominatum*, or *sacrum*, *patella*, *ribs*, *scapula*, *skull*, *sternum*, *thigh*, and *vertebræ*. See WEITT, CLAVICLE, CUBITUS, &c.

FRACTURE, *capillary*. See CAPILLATION.

FRACTURED *limbs*, *extension of*. See EXTENSION.

FRÆNA, a word used by some anatomical writers, as a name for the sockets of the teeth.

FRÆNUM, or FRENUM, *bridle*, in *Anatomy*, a name given to divers ligaments, from their office in retaining and curbing the motions of the parts they are fitted to.

FRÆNUM *linguæ*, or *bridle of the tongue*, is a membranous ligament, which ties the tongue to the os hyoides, larynx, fauces, and lower part of the mouth.

In some subjects the *frænum* runs the whole length of the tongue, to the very tip; in which cases, if it were not cut, it would take away all possibility of speech. See TONGUE *tied*.

FRÆNUM *of the penis* is a slender ligament, whereby the prepuce is tied to the lower part of the glans of the PENIS.

Nature varies in the make of this part; it being so short in some, that unless divided, it would not admit of perfect erection. There is also a kind of little *frænum*, fastened to the lower part of the CLITORIS.

FRAGARIA. See STRAWBERRY.

FRAIGHT, or FREIGHT, in *Navigation* and *Commerce*, the hire of a ship, or of a part of it, for the conveyance and carriage of goods from one part, or place, to another; or the sum agreed on, between the owner and the merchant, for the hire and use of a vessel.

The word is formed of the French *fret*, signifying the same thing; or from *fret*, of *fretum*, an arm of the sea: though others chuse to derive it from the German *fracht*, or the Flemish *wracht*, signifying *carriage*.

The *freight* of a vessel is usually agreed on either at the rate of so much for the voyage, or by the month, or per ton.

Freighting, or letting out vessels on *freight*, or hire, is one of the principal articles in the trade of the Hollanders: they are the carriers of all the nations of Europe, and their purveyors; notwithstanding that their country produces little or nothing, and that they are forced to have every thing necessary for the building of a vessel from other countries.

The principal laws and rules relating to *freighting* are, that if a whole vessel be hired, and the merchant, or person who hires it, do not give it its full load, or burthen, the master of the vessel cannot, without his consent, take in any other goods, without accounting to him for *freight*.

That though the merchant do not load the full quantity of goods agreed on in the CHARTER-*party*, yet he shall pay the whole *freight*; and if he load more, he shall pay for the excess.

If a time be appointed by charter-party, and either the ship be not ready to take in, or the merchant to put on board, the parties are at liberty, with remedy by action for the detriment.

If part be on board, and some misfortune prevent the merchant's sending the whole in time, the master may contract with another, and have *freight* as damage for the time they were on board longer than limited.

On the other hand, if the vessel is not ready, the merchant may ship the remainder of his goods aboard another, and recover damages against the first master or owners: therefore, by the law marine, chance, or other notorious necessity, will excuse the master, but he loses his *freight* till he breaks ground. But if the merchant be in fault, he must answer the damage, or be liable to maintain the crew ten days; and, if after that, the full *freight*; if damage afterwards, it is the merchant's risque: but by the common law, while the goods are on board, the master must see them forth-coming.

If goods are fully laded, and the ship hath broke ground, but the merchant afterwards declines the adventure, and unlades again, by the law marine the *freight* is due.

If a set time be agreed upon between the merchant and master, to begin and end the voyage, it may not be altered by the supercargo, without special commission: and if a master shall fail on his voyage, after the time agreed on for his departure, and damage happens afterwards, he shall make it good. If a ship be freighted from one port to another, thence to a third, &c. and so home to the port whence she first sailed (commonly called a trading voyage), the whole is one and the same voyage, if performed according to the charter-party. If the ship be freighted out and in, no *freight* is due till the voyage is performed; if, therefore the ship perish coming home, the whole *freight* is lost.

The master may set ashore such goods as he finds in his vessel, which were not notified to him; or take them at a higher rate than was agreed on for the rest. But if the master *freight* his ship, and afterwards secretly take in other goods, he loses his *freight*; and if any of the freighter's goods should, for the ship's safety, be cast overboard, the rest shall not be subject to AVERAGE, but the master must make it good.

If a ship be stopped or detained in its course, either through the master's, or the merchant's default, the delinquent shall be accountable to the other. Thus, if the freighter load the ship with prohibited goods, he shall answer the *freight* contracted: but if the ship put into any other port than the is freighted to, the master shall answer damage to the merchant; but if forced in by storm, enemy, or pirates, he must then sail to the stipulated port at his own costs.

If the master be obliged to refit his vessel during the voyage, the merchant shall wait, or else pay the whole *freight*: if the vessel could not be refitted, the master is obliged to hire another immediately, otherwise only to be paid his *freight* in proportion to the part of the voyage performed; though, in case the merchant prove that the vessel, at the time it set sail, was not capable of the voyage, the master must lose his *freight*, and account for damages to the merchant.

Freight shall be paid for merchandizes which the master was obliged to sell for victuals, or refitting, or other necessary occasions, paying for the goods at the rate the rest were sold at, where they were landed.

In case of a prohibition of commerce with the country whither the vessel is bound, so that it is obliged to be brought back again, the master shall only be paid *freight* for going.

And if a ship be stopped or detained in its voyage, by an embargo by order of the prince, there shall neither be any *freight* paid for the time of the detention, in case it be hired per month; nor shall the *freight* be increased, if hired for the voyage; but the pay and the victuals of the sailors, during the detention, shall be deemed AVERAGE.

The master shall take no *freight* for any goods lost by shipwreck, plundered by pirates, or taken by the enemy, unless the ship and goods be redeemed; in which case he shall be paid his *freight* to the place where he was taken, upon contributing to the redemption.

The master shall be paid his *freight* for the goods saved from shipwreck; and in case he cannot get a vessel to carry them unto the place where they were bound, he shall be paid in proportion to the part of the voyage already gone. The ship's lading, in constitution of law, is tacitly obliged for the *freight*; this being in point of payment, preferred before any other debts to which the goods laden are liable, though such were precedent to the *freight*, because the goods remain, as it were, bailed for the same.

The master may not detain any merchandize in his vessel, in default of payment of *freight*; though he may order them to be seized any time, or any where afterwards. If merchandizes in casks, as wines, oils, &c. have so run out in carriage, that the vessels are left empty, or almost empty, the merchant may relinquish them, and the master be obliged to take them for their *freight*; though this does not hold of any other goods damaged, or diminished of themselves, or through accidents.

FRAIGHT is also used for the burthen, or lading of a ship, or the cargo of goods, &c. which she has on board.

FRAIGHT is also a duty of fifty sols per ton, paid to the

crown of France by the masters of all foreign vessels, at their entrance into and going out of the ports and havens of that kingdom. And note, that all vessels not built in France, however they may belong to the subjects of France, are reputed foreigners, and subject to this impost, unless it be made appear, that two thirds of the ship's crew are French.

By the eleventh article of the treaty of commerce, concluded at Utrecht between England and France, this duty of fifty sols per ton was to have been remitted the Englisli; and at the same time, the duty of five shillings sterling to have been superadded in favour of the French: but the execution of that article, as well as the tariff settled between the two nations, has been suspended.

The Dutch, however, and the Hans towns, are exempted from the duty of *freight*.

FRAIL, a basket of rushes, or the like matter, wherein to pack up figs, raisins, &c.

FRAIL also denotes a certain quantity of raisins, about seventy-five pounds.

FRAISE, in *Fortification*, a kind of defence, consisting of pointed stakes, driven parallel to the horizon, into the retrenchments of a camp, a half moon, or the like, to ward off and prevent any approach or scalade.

Fraises differ from palisades chiefly in this, that the latter stand perpendicular to the horizon; and the former jet out parallel to the horizon, at least nearly so, being usually made a little sloping, or with the points hanging down. *Fraises* are chiefly used in retrenchments, and other works thrown up of earth: sometimes they are found under the parapet of a rampart, serving instead of the cordon of stone used in stone works.

FRAISING *of a battalion*, is the lining it all round with pikes, in case of being charged by a body of horse.

FRAMBOISE, a name used by some for the *rubus* or blackberry bush. See RASPBERRY.

FRAME, in *Joinery*, &c. a kind of case, wherein a thing is set, or inclosed, or even supported; as a window *frame*, a *frame* of a picture, of a table, &c.

FRAME is also a machine, used in divers arts. The printers *frame* is more usually called a CASE.

The founders *frame* is a kind of ledge, inclosing a board, which being filled with wetted sand, serves as a mould to cast their work in. See FOUNDERY.

FRAME is more particularly used for a sort of loom, whereon artizans stretch their linens, silks, stuffs, &c. to be embroidered, quilted, or the like.

FRAME, among *Painters*, &c. is a kind of square, composed of four long pieces, or slips of wood, joined together; the intermediate space whereof is divided by little strings or threads, into a great number of little squares, like the meshes of a net; and for that reason sometimes called *reticulum*.

Its use is in reducing of figures from great to small, or augmenting their size from small to great. See DESIGNING.

FRAMING *of a house*, all the timber-work therein, viz. the cancels, flooring, partitioning, roofing, cieling, beams, shittering, &c.

FRAMPOLE *fence*, a privilege enjoyed by the tenants of the manor of Writtel, in Essex; whereby they are entitled to the wood growing on the fence; and as many trees or poles as they can reach from the top of the ditch with the helve of an ax, toward the repair of their fence.

The chief justice Brampton, whilst steward of this court, acknowledged he could not find out the reason why these fences were called *frampole*. It may come from the Saxon *fremfol*, *profitable*; or may be a corruption of *frame pole*, because the poles are free for the tenant to take.

FRANC. See FRANK.

FRANCA, in *Botany*, the name given by Micheli to a genus of plants, since called by Linnæus FRANKENIA.

FRANCHISE, a privilege or exemption from ordinary jurisdiction.

FRANCHISE is also used for an immunity from the ordinary tributes and taxes.

This is either real, or personal; that is, either belonging immediately to the person; or accruing on account of this or that place, or office of IMMUNITY.

These *franchises*, being royal privileges, or branches of the king's prerogative, subsisting in the hands of a subject, are derived from the crown by grant or charter, and, in some cases, are held by prescription and usage. They may be vested either in natural persons, or bodies politic; in one man, or in many; but the same identical *franchise* that has before been granted to one, cannot be bestowed on another, for that would prejudice the former grant. The principal kinds of *franchises* are the following: to be a COUNTY palatine is a *franchise* vested in a number of persons. It is likewise a *franchise* for a number of persons to be incorporated, and subsist as a body politic, with a power to maintain perpetual succession, and do other corporate acts; and each individual member of such corporation is also said to have a *franchise* or freedom. Other *franchises* are to hold a court leet; to have a manor or lordship; or, at least, to have a lordship paramount; to have waifs, wrecks, estrays, treasure-trove, royal-fish, forfeitures, and deodands; to have a court of one's own, or liberty of holding pleas and trying causes; to have the cognisance of pleas, which is a still greater liberty, being an exclusive right, so that no other court shall try causes arising within that jurisdiction; to have a bailiwick, or liberty exempt from the sheriff of the county, wherein the grantee only and his officers are to execute all process; to have a fair or market, with the right of taking toll, either there or at any other public places, as bridges, wharfs, and the like; which toll must have a reasonable cause of commencement, else the *franchise* is illegal and void; or, lastly, to have a forest, chase, park, warren or fishery, endowed with privileges of royalty. See the several articles above recited.

FRANCHISE, *Nonuser of*. See QUO *warranto*.

FRANCHISE *usurpation of*, is remedied by suing for damages, by a special action on the case; or, in case of toll, the injured person may take a distress if he pleases.

FRANCHISE is also used for an asylum, or sanctuary, where people are secure of their persons, &c.

Churches and monasteries in Spain are *franchises* for criminals; so were they anciently in England, till they were abused to such a degree, that there was a necessity for abolishing the custom.

One of the most remarkable capitulars made by Charlemagne in his palace of Heristal, in 779, was that relating to the *franchises* of churches. The right of *franchise* was held so sacred, that even the less religious kings observed it to a degree of scrupulousness; but to such excess in time was it carried, that Charlemagne resolved to reduce it. Accordingly he forbad any provision being carried to criminals retired into churches for refuge.

FRANCHISE *of quarters*, is a certain space, or district at Rome, wherein are the houses of the ambassadors of the princes of Europe; and where such as retire, cannot be arrested, or seized by the sbirri, or serjeants, nor prosecuted at law.

The people of Rome look on this as an old usurpation, and a scandalous privilege, which ambassadors, out of a jealousy of their power, carried to a great length in the fifteenth century, by enlarging insensibly the dependencies of their palaces or houses, within which the right of *franchise* was anciently confined. Several of the popes, Julius III. Pius XIV. Gregory XIII. and Sixtus V. published bulls and ordinances against this abuse; which had refused so considerable a part of the city from their authority, and rendered it a retreat for the most abandoned persons.

At length Innocent XI. expressly refused to receive any more ambassadors but such as would make a formal renunciation of the *franchise of quarters*.

FRANCHISE *royal*, is a place where the king's writ runs not; as at Chester, and Durham; and anciently at Tyndal, and Hexhamshire in Northumberland. But Bracton says, that a *franchise royal* is where the king grants to one and his heirs an exemption of toll, &c. See FRANCHISE.

FRANCHISING. See ENFRANCHISEMENT, and MANUMISSION.

FRANCIGENA, or FRENCHMAN, in our *Ancient Customs*, was a general appellation of all foreigners; i. e. all persons who could not prove themselves Englishmen.

FRANCISCANS, in *Ecclesiastical History*, are religious of the order of St. Francis, founded by him in the year 1209. Francis was the son of a merchant of Assisi, in the province of Umbria, who, having led a dissolute life, was reclaimed by a fit of sickness; and afterwards fell into an extravagant kind of devotion, that looked less like religion than alienation of mind. Soon after this, viz. in the year 1208, hearing the passage repeated, Matt. x. 9, 10. in which Christ address's his apostles, *Provide neither gold, nor silver*, &c. he was led to consider a voluntary and absolute poverty as the essence of the Gospel, and to prescribe this poverty as a sacred rule both to himself and to the few that followed him. This new society, which appeared to Innocent III. extremely adapted to the present state of the church, and proper to retrieve its declining credit, was solemnly approved and confirmed by Honorius III. in 1223, and had made a considerable progress before the death of its founder in 1226. Francis, through an excessive humility, would not suffer the monks of his order to be called *friars*, i. e. *brethren* or *friars*, but *fratercini*, i. e. *little brethren*, or *friarsminors*, by which denomination they still continue to be distinguished. They are also called *Grey Friars*, on account of the colour of their cloathing, and CORDELIERS, &c.

&c. The *Franciscans* and DOMINICANS were zealous and active friends to the papal hierarchy, and, in return, were distinguished by peculiar privileges and honourable employments. The *Franciscans*, in particular, were invested with the treasure of ample and extensive indulgences, the distribution of which was committed to them by the popes, as a means of subsistence, and a rich indemnification for their voluntary poverty. In consequence of this grant, the rule of the founder, which absolutely prohibited both personal and collective property, so that neither the individual nor the community were permitted to possess either fund, revenue, or any worldly goods, was considered as too strict and severe, and dispensed with soon after his death. In 1231, Gregory IX. published an interpretation of this rule, mitigating its rigour; which was further confirmed by Innocent IV. in 1245, and by Alexander IV. in 1247. These milder alterations were zealously opposed by a branch of the *Franciscans*, called the *spirituals*; and their complaints were regarded by Nicholas III. who, in 1279, published a famous constitution, confirming the rule of St. Francis, and containing an elaborate explication of the maxims it recommended, and the duties it prescribed. In 1287, Matthew of Aqua Sparta, being elected general of the order, discouraged the ancient discipline of the *Franciscans*, and indulged his monks in abandoning even the appearance of poverty; and this conduct inflamed the indignation of the *spirituals* or stricter *Franciscans*; so that from the year 1290, seditions and schisms arose in an order, that had been so famous for its pretended disinterestedness and humility. Such was the enthusiastic frenzy of the *Franciscans*, that they impiously maintained, that the founder of their order was a second Christ, in all respects similar to the first; and that their institution and discipline were the true gospel of Jesus. Accordingly, Albizi, a *Franciscan* of Pisa, published a book, in 1383, with the applause of his order, entitled, The Book of the Conformities of St. Francis with Jesus Christ. In the beginning of this century the whole *Franciscan* order was divided into two parties; the one, embracing the severe discipline and absolute poverty of St. Francis, were called *spirituals*; and the other, who insisted on mitigating the austere injunctions of their founder, were denominated *brethren of the community*. These wore long, loose, and good habits, with large hoods; the former were clad in a straight, coarse, and short dress, pretending, that this dress was enjoined by St. Francis, and that no power on earth had a right to alter it. Neither the moderation of Clement V. nor the violence of John XXII. could appease the tumult, occasioned by these two parties: however, their rage subsided from the year 1329. In 1368 these two parties were formed into two large bodies, comprehending the whole *Franciscan* order, which subsist to this day; viz. the CONVENTUAL *brethren*, and the *brethren of the* OBSERVANCE or *observation*, from whom sprang the CAPUCHINS and RECOLLECTS. Mosh. Eccl. Hist. vol. iii. See *Nuns of St.* CLARE and FRIARS.

The general opinion is, that the *Franciscans* came into England in the year 1224, and had their first house at Canterbury, and their second at London; but there is no certain account of their being here till king Henry VII. built two or three houses for them. At the dissolution of the monasteries, the conventual *Franciscans* had about fifty-five houses, which were under seven custodies or wardenships; viz. those of London, York, Cambridge, Bristol, Oxford, Newcastle, and Worcester.

FRANCOLIN, in *Ornithology*. See ATTAGEN.

FRANGIPANE, an exquisite kind of perfume, frequently given to the leather whereof gloves, purses, bags, &c. are made.

It takes its name from a Roman nobleman, of the ancient family of Frangipani, who was the inventor of it.

There is also a kind of perfumed liquor of the same denomination, said to have been invented by a grandson of Mutio Frangipani; and also a perfumed kind of *ras solis*, called by the same name.

FRANGULA, in *Botany*. See *Berry-bearing* ALDER.

FRANK, or FRANC, a term literally signifying free and open, or exempt from public impositions and charges; as *frank* confession, *frank* fair, *frank* letter, &c.

The term *frank* is much used in our ancient customs and tenure; where it receives various particular modifications and meanings, according to the words it is compounded with; as,

FRANK *allen*, or *allodium*, is a land, tenement, or demesne, that is not held of any superior lord.

FRANK *almoin*, or *free alms*, is a tenure of lands or tenements bestowed on God; that is, given to such people as devote themselves to the service of God, in pure and perpetual alms; or, it is a tenure, whereby a religious corporation, aggregate or sole, holdeth lands of the donor to them and their successors for ever.

Whence the feoffers, or givers, cannot demand any terrestrial service, so long as the land remains in the hands of the feoffees.

The service which the feoffees were bound to render for these lands is not certainly defined; but only, in general, to pray for the souls of the donor and his heirs, dead or alive; and, therefore, they did no fealty, which is incident to all other services but this, because this divine service was of a more exalted nature. This is the tenure, by which all the ancient monasteries and religious houses held their lands; and by which the parochial clergy, and many ecclesiastical and eleemosynary foundations, hold them at this day. This was an old Saxon tenure, and continued under the Norman revolution, on account of the respect shewn to religion, and religious men, in ancient times; and for this reason, tenants in *frank almoign* were discharged of all other services, except the *trinoda necessitas*, of repairing the highways, building castles, and repelling invasions. And this tenure is still distinct from all others, being not in the least feodal, but merely spiritual; for, if the service be neglected, the law gives no remedy by distress or otherwise to the lord of whom the lands are holden; but merely a complaint to the ordinary or visitor to correct it.

Britton mentions another kind of land given in alms, but not free alms; the tenants being tied in certain services to the feoffer: as to sing so many masses, distribute such a sum in alms, and the like; and this tenure by divine service differs from the former, because for this, unperformed, the lord might distrain, without any complaint to the visitor. All such donations are now out of use; for since the statute of *quia emptores*, 18 Edw. I. none but the king can give lands to be holden by this tenure.

FRANK *bank*. See FREE *bench*.

FRANK *chace* denotes liberty of free chace, in a circuit adjoining to a forest, on account of which, men, though they have land of their own within that compass, are forbidden to cut down wood, without the view of the forester; though it be their own demesne. See CHASE.

FRANK *fee*, *feodum francum*, as defined by Brook, is that which is in the hands of the king, or lord of the manor; being ancient demesne of the crown.

FRANK *fee*, *feodum liberum*, according to some, denotes that for which no service is performed to any lord.

According to Fachin, lib. vii. cap. 39. lands held in *frank fee* were exempted from all service, except homage.

In contradistinction to that in the tenants hands, which is only ancient demesne.

In the reg. of writs, *frank fee* is said to be that which a man holds at common law to him, and his heirs; and not by such service as is required in ancient demesne, according to the custom of the manor.

It is added, that the land in the hands of king Edward the Confessor, at the making of Domesday book, is ancient demesne; and all the rest, *frank fee*. On which footing, all the lands of the realm are either ancient demesne, or *frank fee*.

Others define *frank fee* to be a tenure in fee-simple, of lands pleadable at common law; and not in ancient demesne. See FEE.

FRANK *ferm*, *firma libera*, denotes lands or tenements, wherein the nature of the fee is changed, by feoffment, from knight's service, to a certain yearly service; and whence neither homage, wardship, marriage, nor relief, may be demanded; nor any other service not contained in the feoffment. See FEE *farm*, and SOCAGE.

FRANK *fold* is where the lord hath the benefit of folding his tenants sheep, within his manor, for the manuring of his land.

FRANK *language*, or *lingua* FRANCA, is a kind of jargon, spoken on the Mediterranean, and particularly throughout the coasts and ports of the Levant; composed of Italian, Spanish, French, vulgar Greek, and other languages.

The *lingua Franca* is the trading language; and is thus called from the *Franks*, a common appellation given in the Levant to all the European merchants and traders, who come thither to traffick.

In this language, if it may be so called, nothing but the infinite mood of each verb is used; this serving for all the tenses and moods of the conjugation; and yet this lame, mutilated diction, this barbarous medley, is learnt and understood by the merchants and mariners of all nations who repair thither.

FRANK *law*, *lex libera*, is the benefit of the free and common law of the land.

He that for any offence, as conspiracy, &c. loseth his *frank law*, incurs these inconveniencies: 1. That he may not be impanelled on any jury or assize: or otherwise used as an evidence, or witness to the truth. 2. That if he have any thing to do in the king's court, he must not approach it in person, but appoint his attorney. 3. That his

his lands, goods, and chattels, be seized into the king's hands; and his lands be estreated, his trees rooted up, and his body committed to custody.

FRANK *letters*, or *letters free of passage*. The privilege of such letters was claimed by the house of commons in 1660, when the first legal settlement of the present POST-OFFICE was made; but afterwards dropped on a private assurance from the crown, that this privilege should be allowed the members. Accordingly, a warrant was constantly issued to the post-master general, directing the allowance thereof to the extent of two ounces in weight; till at length it was expressly confirmed by statute 4 Geo. III. cap. 24. which also many new regulations, rendered necessary by the abuses crept into the practice of franking; whereby the annual amount of *franked letters* had gradually increased from 23,600*l.* in 1715, to 170,700*l.* in 1764. Blackst. Com. vol. i. p. 322.

FRANK *marriage*, *liberum maritagium*, is a tenure in tail special, whereby lands, or tenements, are held to a person and his wife, and the heirs of their bodies, on condition of doing fealty to the donor, till the fourth degree of consanguinity between the issues of the donor and donee.

Pleta gives this reason, why the heirs do no service, till the fourth degree *non donatori, vel eorum hæredes, pro homagio recipiendum a reverentiæ repellentur*; and why, in the fourth descent, they shall do service to the donor, *quia in quarto gradu sufficienter propinquitur quod terra ob defectu hæredum donatorium non reverteretur.*

Frank marriage is expressed, by Bracton, to be that where the donor intends, that the land thus bestowed shall remain quiet, and free from all secular service that might be annexed to the fee; so that he who gave it shall claim no manner of service from it, until the third heir, and the fourth descent, or degree; reckoning the donee in the first degree, his heir in the second, the heir of him in the third, and his, again, in the fourth; but afterwards the same land to become subject to all the former services; as being then supposed to revert to the lord, for want of heirs.

The lands otherwise given in marriage, viz. *servitia ex-ligata*, were with a reservation of the services due to the lord, which the donee and his heirs, were bound to perform for ever: only, homage was not to commence till the fourth degree, when both service and homage were to be enjoined for ever.

FRANK-*pledge* signifies a pledge or surety for the behaviour of a freeman; called also FRITHBURH.

The ancient custom of England, for preservation of the public peace, was, that every free-born man, at fourteen years of age (religious persons, clerks, knights, and their eldest sons, excepted) should find surety for his truth towards the king and his subjects, or else to be kept in prison.

Accordingly, a number of neighbours became interchangeably bound for each other, to see each man of their pledge forthcoming at all times; or to answer for the offence committed by any one gone away; so that whenever one offended, it was presently inquired in what *pledge* he was; and then those of the pledge either brought him forth within one and thirty days to his answer; or they satisfied for his offence.

This custom was called *frank-pledge*; and the circuit it extended to, *decenna*, because it usually consisted of ten households; and every person thus bound for himself and neighbours was called a *decennier*. See DECINERS.

In observance of this custom, the sheriffs at every county-court did from time to time take the oaths of young persons, as they arrived at the age of fourteen; and see they were settled in one *decenna*, or *dozein*, or another: whereupon this branch of the sheriff's office and authority was called *visus franci plegii*, i. e. *view of frank pledge*.

Omnis homo, free liber, sive servus, aut alius, vel habet esse in franco plegio, aut de alicujus manupastio, nisi sit aliquis itinerant de loco in locum, qui non potest se tenere ad unum quem ad alium, vel qui habet quod sufficiat pro tranco plegio, sicut dignitatem, vel ordinem, vel liberum tenementum, vel in civitate rem immobilem, &c. Bracton, lib. iii. Tract. de Coron. cap. 12.

FRANK *service*. See SERVICE.

FRANK *tenement*. See TENEMENT and FREEHOLD.

FRANC, or FRANC, also denotes an ancient coin, struck, and current in France; thus called from its impression, which represented a Frenchman, sometimes on horseback, and sometimes on foot.

The *franc* was either of gold or silver: the first was worth somewhat more than the ecu d'or, or gold crown. See CROWN.

The second was a third of the first; but these coins have been long disused.

The term *franc*, however, is still retained as the name of a money of account. In this sense it is equivalent to a livre, or twenty sols, or a third of a French crown. Thus they say indifferently, a hundred *francs*, or a hundred livres.

FRANKENIA, in *Botany*, the name given by Linnæus to a genus of plants of the *hexandria monogynia* class, called by Micheli, *frankenia*. The perianthium is permanent, and is composed of one leaf of an oblong tubular form, divided into five segments at the edge; the flower consists of five petals, the ungues of which are narrow, and of the length of the cup, and the tops roundish and expanded; the stamina are ten filaments, longer than the tube; the apices are simple; the germen of the pistil is roundish; the style is capillary, and of the length of the stamina; the stigma is divided into six parts: the fruit is an oval capsule covered with the cup, and formed of three valves, but containing only one cell, in which are a great number of small seeds of an oval figure. There are three species.

FRANKINCENSE, or simply INCENSE, an odoriferous aromatic gum or resin, anciently burnt in temples, as a perfume, and now used in pharmacy as an agglutinant and strengthener.

The word is formed from the Latin *incensum*, *burnt*; as alluding to its ancient use in temples.

Frankincense distils from incisions made in a tree called *arbor thurifera*, during the heats of summer. But, notwithstanding the great use of this gum, both in the ancient religion, and the modern medicine, the tree that produces it, or even the place where the tree grows, is but little known.

The most common opinion has always been, that it was brought from Arabia Felix, and was found near the city of Saba; whence its epithet *Sabæum*; and yet the name *olibanum*, which it sometimes also bears, seems to intimate, that there are of these thuriferous or incense bearing trees in the Holy Land near mount Lebanon. And travellers are positive, that there are others in the East Indies.

Nor are we less at a loss as to the form or kind of the tree from which it flows. Pliny contents himself to say, that it at first resembles the pear tree; then the mastich tree; then the laurel; but that in reality it is a kind of turpentine-tree.

Frankincense is usually divided into *male* and *female*.

The best *male incense*, *thus masculum*, called also *olibanum*, is in fair white bits, or tears, a little yellowish, of a bitter disagreeable taste; and when chewed, it promotes the flux of saliva, which becomes white. When laid on coals, or a red-hot iron, it flames and burns with a strong and not unpleasant smell. On trituration with water, the gummy part dissolves into a milky liquor, which deposits a resinous matter, and being gently inspissated, leaves a yellow extract, retaining the greatest part of the smell as well as taste of the *olibanum*. Rectified spirit dissolves less than water.

It is called *male* in respect of its tears, which are larger than those of the common or female.

That brought from the Indies is not near so good as that from Arabia, or mount Lebanon; it is sometimes called *incense of Mocha*; though it be not brought from that city. It is often in a mass, but sometimes in loose drops or tears; somewhat reddish, and bitter to the taste. Some sell this for the true bdellium.

Male incense, or *olibanum*, is an ingredient in divers Galenical and chemical preparations: it warms, dries, and binds; and is used not only in divers diseases of the head and breast, but in vomitings, diarrhœas and dysenteries. The dose is from a scruple to a dram or more. Externally it is applied to strengthen the brain, and heal wounds. Some use it to assuage the tooth-ach; but it is apt to spoil the good teeth.

As for *female incense*, or *frankincense*, authors describe it to be softer, and more resinous, but of less virtue than the former. This common *frankincense* is brought to us in little globes or masses, of a brownish or yellowish colour on the outside, internally whitish, and variegated with whitish specks. It is supposed to be the produce of the pine that yields the common turpentine, and to concrete upon the surface of the terebinthinate juice, soon after it has issued from the tree. This resin has a bitterish, acrid, unpleasant taste, and no considerable smell; it dissolves totally in rectified spirit, but is scarcely acted upon by watery menstrua. It may be looked upon as a mild corroborant; though at present it is little or no made use of than as an ingredient in theriaca, and externally in plasters. Lewis, Mat. Med.

Bark of incense, *cortex thuris*, is the bark of the tree whence the *incense* flows, which has the same qualities with the *incense* itself.

There is another bark brought from the Indies, called also *bark of incense*, and sometimes *Jews incense*, because the Jews make frequent use thereof in their perfume: this is the *cortex cluteriæ*.

Manna of incense is the flour or farina of *incense*, occa-

floned by the frictions of the grains againſt each other in the ſacks wherein they carry it.

There is alſo a ſort of *incenſe*, which is a preparation of it, burnt like reſin to make lamp-black.

Frankincenſe was formerly burnt in the temples of all religions, to do honour to the divinities that were there adored. Many of the primitive Chriſtians were put to death, becauſe they would not offer *incenſe* to idols.

In the Romiſh church they ſtill retain the uſe of *incenſe* in ſome of their ceremonies; always at high-maſs, and at the elevation of the hoſt at veſpers; and at ſolemn funerals, beſtowing it on ſuch perſons as they would honour, as on prelates, &c. and ſometimes alſo on the people.

FRANKS, FRANCE, FRANCIS, or FRANQUIS, a name which the Turks, Arabs, Greeks, &c. give to all the people of the weſtern parts of Europe.

The appellation is commonly ſuppoſed to have had its riſe in Aſia, at the time of the croiſades; when the French made the moſt conſiderable figure among the croiſiers; from which time the Turks, Saracens, Greeks, Abyſſinians, &c. uſed it as a common term for all the Chriſtians of Europe; and called Europe itſelf *Frankiſtan*.

The Arabs and Mahometans, ſays M. d'Herbelot, apply the term *Franks* not only to the French (to whom the name originally belonged) but alſo to the Latins and Europeans in general.

But F. Goar, in his notes on Cedrinus, cap. 5. n. 43. furniſhes another origin of the appellation *Franks*, of greater antiquity than the former. He obſerves, that the Greeks at firſt confined the name to the *Franci*, i. e. the German nations, who had ſettled themſelves in France or Gaul: but afterwards they gave the ſame name to the Apulians and Calabrians, after they had been conquered by the Normans: and at length the name was farther extended to all the Latins.

In this ſenſe is the word uſed by divers Greek writers: as Cinnamus, &c. who to diſtinguiſh the French, call them the *weſtern Franks*.

Du-Cange adds, that about the time of Charlemagne, they diſtinguiſhed eaſtern France, weſtern France, Latin, or Roman France, and German France, which was the ancient France, afterwards called Franconia.

FRAPPING, in *Sea-language*, denotes the act of croſſing and drawing together the ſeveral parts of a tackle, or other compoſition of ropes, which had been already ſtraitened to their utmoſt extent, reſembling the operation of beating up a drum, &c. The *frapping* increaſes the tenſion, and adds to the ſecurity acquired by the purchaſe. Hence the cat-harpings are no other than *frappings* to the ſhrouds.

Frapping a ſhip, is the act of paſſing three, four, or five turns of a cable round the hull, or frame of a ſhip, in the middle, to ſupport her in a great ſtorm, when it is apprehended ſhe is not ſtrong enough to reſiſt the violent efforts of the ſea. This is ſeldom uſed, except in old ſhips. Falconer.

FRASSETUM, in *our Old Writers*, is taken for a wood, or woody ground, where aſh grows. 1 Inſt. 4.

The word is a corruption of the Latin *fraxinetum*, which ſignifies the ſame.

FRATERIA, of *frater*, *brother*, a fraternity, brotherhood, or ſociety of religious perſons, who were bound to pray for the good health and life, &c. of their living brethren, and the ſouls of thoſe that were dead. In the ſtatutes of the cathedral church of St. Paul, London, collected by Ralph Baldock, dean, 1295, there is one chapter De frateria *benefactorum eccleſiæ S. Pauli, &c.*

FRATERCULA, in *Zoology*, a name by which Geſner and Aldrovand have called the *anas arctica cloſii*. See PUFFIN.

FRATERNITY, *brotherhood*, the relation or union of brothers, friends, partners, and aſſociates, &c.

FRATERNITY, in *a civil ſenſe*, is uſed for a guild, aſſociation, or ſociety of perſons, united into a body, for ſome common intereſt or advantage.

For the origin, uſe, &c. of *fraternities*, ſee COMPANY and GILD.

FRATERNITY, in *a religious ſenſe*, is a ſociety of perſons meeting together to perform ſome exerciſes of devotion, or divine worſhip.

In the Romiſh church, ſuch *fraternities* are very numerous and conſiderable, being moſt of them eſtabliſhed by royal patents; as the *fraternity* of the ROSARY; the *fraternity* of the SCAPULARY; of St. Francis's Cord; ſee CORDELIERS and FRANCISCANS. The biſhop may hinder the eſtabliſhment of any ſuch *fraternity* in his dioceſe.

At Rome there is a *fraternity*, called the *archi-fraternity*, or *grand fraternity*, under the title of *Our Lady of the Suffrages*, eſtabliſhed in favour of the ſouls in purgatory, approved and confirmed by a bull of pope Clement VIII. in 1594. See BRETHREN and BROTHERS.

There are nine different ſorts of *fraternities*, or confrairies, in France, viz. 1. Of Devotion. 2. Of Charity, or Mercy. 3. Of Penitents, under divers names. 4. Of Pilgrimage. 5. Of Merchants to procure the divine favour on their endeavours. 6. Of Officers of Juſtice. 7. Of the ſufferings of Chriſt. 8. Of Arts and Trades of divers kinds. And, 9. Of Factions.

Fraternities, in Latin called *ſodalitates*, derive their origin from the heathens, as is ſhewn by Polydore Virgil, in his book De Inventoribus Rerum. But the good uſe made of them by the Chriſtians has effectually purged them of any impurities derived from ſo ill a ſource.

Numa Pompilius is ſaid to have eſtabliſhed *fraternities* of all arts and trades in ancient Rome, and to have preſcribed the ſacrifices each profeſſion was to perform to the patron or tutelary gods he had aſſigned them.

FRATERNITY *of the holy Trinity*. See TRINITY.

FRATERNITY is alſo a title or quality which kings and emperors gave to each other; ſo alſo do biſhops and monks. We meet with it frequently in authors under the eaſtern empire, both Greek and Latin: the Greek term is *adelphotes*, *fraternitas*.

FRATERNITY *of arms* was an alliance, or aſſociation in arms, anciently concluded between two knights, who thereby agreed to go together, ſhare their fortune, and mutually aſſiſt each other againſt all the world.

Bertrand du Gueſclin and Oliver Cliſſon twore a *fraternity* of arms in the year 1379, laying their hands on the goſpels. Hiſt. de Bret. tom. 1. p. 395.

FRATERNITY *of St. Catharine*. See CATHARINE.

FRATRES *Arvales*. See ARVALES.

FRATRES *conjurati*, in *our ancient Law-books*, &c. denote ſworn brothers, or companions.

Sometimes they are alſo ſo called who were ſworn to defend the king againſt his enemies, leg. W. 1. cap. 59. *Præcipimus, ut omnes libri homines ſint* fratres conjurati *ad monarchiam noſtram & regnum noſtrum contra inimicos poſſe jus defendandum*.

FRATRES *gaudentes*. See *Joyful* BROTHERS.

FRATRIAGE, FRATRIAGIUM, or FREERAGE, the partition among brothers, or coheirs, coming to the ſame inheritance or ſucceſſion.

FRATRIAGE is more particularly uſed for that part of the inheritance which comes to the youngeſt brothers.

Whatever the cadets, or younger brothers, poſſeſs of the father's eſtate, they poſſeſs *ratione fratriagii*, and they are to do homage for the whole to the ſuperior lord.

FRATRICELLI, in *Eccleſiaſtical Hiſtory*, an enthuſiaſtic ſect of FRANCISCANS, which roſe in Italy, and particularly in the marquiſate of Ancona, about the year 1294.

The word is an Italian diminutive, ſignifying *fraterculi*, or little brothers: and was here uſed as a term of deriſion, as they were moſt of them apoſtate monks, whom the Italians call *frotelli*, or *fratricelli*.

For this reaſon the term *fratricelli*, as a nick name, was given to many other ſects, as the Cathariſts, the Waldenſes, &c. however different in their opinions and in their conduct. But this denomination applied to the auſtere part of the Franciſcans was conſidered as honourable. See FRANCISCANS.

The founders were P. Maurano, and P. de Foſſombroni, who having obtained of pope Celeſtin V. a permiſſion to live in ſolitude, after the manner of hermits, and to obſerve the rule of St. Francis in all its rigour, ſeveral idle vagabond monks joined them, who, living after their own fancies, and making all perfection to conſiſt in poverty, were ſoon condemned by pope Boniface VIII. and his ſucceſſor, and the inquiſitors ordered to proceed againſt them as heretics: which commiſſion they executed with their uſual barbarity. Upon this, retiring into Sicily, Peter John Olivi de Serignan had no ſooner publiſhed his Comment on the Apocalypſe, than they adopted his errors.

They held the Romiſh church to be Babylon, and propoſed to eſtabliſh another far more perfect one: they maintained, that the rule of St. Francis was the evangeliſtical rule obſerved by Jeſus Chriſt, and his apoſtles.

They foretold the reformation of the church, and the reſtoration of the true goſpel of Chriſt, by the genuine followers of St. Francis, and declared their aſſent to almoſt all the doctrines which were publiſhed under the name of the abbot Joachim, in the Introduction to the everlaſting Goſpel, a book publiſhed in 1250, and explained by one of the *ſpiritual* friars whoſe name was Gerhard. Among other enormities inculcated in this book, it is pretended that St. Francis was the angel mentioned in Rev. xiv. 6. and had promulgated to the world the true and everlaſting goſpel of God; that the goſpel of Chriſt was to be abrogated in 1260, and to give place to this new and everlaſting goſpel, which was to be ſub-

stituted in its room; and that the ministers of this great reformation were to be humble and bare-footed friars, destitute of all wordly employments.

Some say they even elected a pope of their new church; at least they appointed a general, with superiors, and built monasteries, &c. Beside the opinions of Olivi, they held, that the sacraments of the church were invalid; because those who administered them, had no longer any power or jurisdiction.

They were condemned afresh by pope John XXII. in consequence of whose cruelty they regarded him as the true antichrist; but several of them returning into Germany, were sheltered by Lewis, duke of Bavaria, the emperor.

There are authentic records, from which it appears, that no less than two thousand persons were burnt by the inquisition, from the year 1318 to the time of Innocent VI. for their inflexible attachment to the poverty of St. Francis. The severities against them were again revived towards the close of the fifteenth century by pope Nicholas V. and his successors. However, notwithstanding all the persecutions which this sect endured, they were not sufficient to extinguish it; for it subsisted until the times of the reformation in Germany, when its remaining votaries adopted the cause, and embraced the doctrine and discipline of Luther. And this has led the popish writers to charge the *fraticelli* with many enormities, some of which are recounted by M. Bayle, art. *Fraticelli*.

The *fraticelli* had divers other denominations: they were called *fratricelli*, according to some, because they lived in community, in imitation of the primitive Christians, or rather through the humility of the founder of the Franciscan order, to which the *fraticelli* originally belonged; *dulcini*, from one of their doctors; BIZOCHI, BEGUINS, and BEGHARDI.

FRATRICIDE, of *frater*, *brother*, and *cædo*, *I kill*, the crime of murdering one's brother. See PARRICIDE.

Cain committed the first *fratricide*; and the empire of Rome began with a *fratricide*.

FRAUD, FRAUS, a secret underhand deceit, or injury done to any one.

To export or import goods by *fraud*, or fraudulently, is to do it by indirect ways, in order to avoid the paying of duty, &c. if they be permitted goods; or if they be contraband goods, to avoid the penalties adjudged by the laws.

A fraudulent conveyance of lands or goods to deceive creditors, or to defraud purchasers, is void in law; and the persons justifying or putting off such grants as good, shall forfeit a year's value of the lands, and the full value of the goods and chattels, and likewise be imprisoned. The several marks of *fraud* in a gift or grant of goods are the following: 1. If it be general, without exception of some things of necessity. 2. If the donor still possesses and uses the goods. 3. If the deed be made in secret. 4. If there be a trust between the parties. 5. If it be made while the action is depending. When a person is party to a *fraud*, all that follows thereupon will be intended to be done by him, though *fraud* shall not be presumed or adjudged to be so, until it be found by a jury. The statute of *frauds*, 29 Car. II. cap. 3. requires that contracts and agreements, leases, and devises of land, be in writing. And devises of land, rents, &c. are deemed fraudulent and void, against creditors, upon bonds or other specialties, 3 and 4 William and Mary, cap. 14. See CHEATS.

FRAUS *legis*; if a person, having no manner of title to a house, procure an affidavit of the service of a declaration in ejectment, and thereupon gets judgment; and, by virtue of a writ of *hab. fac. possessionem*, turns the owner out of possession of the house, and seizes and converts the goods therein to his own use; he may be punished as a felon; because he used the process of the law with a felonious purpose, in *fraudem legis*.

FRAXINELLA, in *Botany*. See DITTANY.

FRAXINUS, in *Botany*. See ASH.

FRAY, merely signifies to fret; as cloth or stuff does by rubbing, or over-much wearing.

Among hunters a deer is said to *fray his head*, when he rubs it against a tree, to cause the skins of his new horns to come off.

FREAM, among *Farmers*, arable or ploughed land worn out of heart, and laid fallow till it recovers.

FREAZE, among *Sportsmen*, a term used for the noise of a boar in cutting time.

FRECKLES, *lentil*, sluttish spots, sprinkled on the skin of the face or hands; particularly in persons of the fairest skins, and during the hot seasons, after being exposed to the sun and air. They are supposed to be formed of fuliginous vapours, stopped and congulated in the skin. Vide Turner's Discourse of the Skin, p. 256.

They are called in Latin *lentigines*, from their resemblance in size and colour to a lentil; by the French they are called *rousseurs*, and *hrun, de Judas*; by the Italians *rossure* and *lentigini*.

Freckles seem to be only the earthly, oily, and saline part, of the sweat, retained in the *pleasi* or mallea of the skin. While the aqueous liquor, which was their vehicle, is evaporated by the heat of the body, these grosser parts are gradually accumulated, till the mallea are full. Some part of this sweat is continually oozing through the cuticle; and, being of a viscid nature, retains the dirt, dust, &c. that fly about the face. This viscid matter on the surface of the *freckles* will stick there, notwithstanding any repeated wipings, which rather condense, and press it into the cavities thereof, than clear it off.

They are found more about the nose, and backs of the hands, than any where else; because the skin is more stretched there, and consequently the pores more open to receive the dust, &c.

It follows that there can scarce be any such thing as an adequate remedy, or preventive, of *freckles*. Temporary ones there may be, which shall draw out and dissipate what matter is already gathered; but the pores will fill up again in time.

Bullocks gall, mixed with alum, and, after the alum has precipitated, exposed three or four months to the sun in a close phial, Mons. Homberg shews, is one of the best remedies known for *freckles*. It acts as a laxative, and enters the pores, and dilutes and dissolves the coagulum of the *freckles*. Mem. de l'Acad. Royal. des Sciences, an. 1709. p. 472, &c. See the method of preparing and using it under GALL.

FREDUM, in *Antiquity*, a composition made by a criminal to be freed from prosecution, a third part of which was paid into the fiscus or exchequer; or it was the price paid to the magistrate for protection against the violence of resentment. Montesq. de l'Esprit des Loix, lib. xxx. cap. 20. and Robertson's Hist. vol. i. chap. v. p. 361.

FREE, a term variously used; but generally in opposition to constrained, confined, or necessitated. See FRANK.

Thus, a man is said to be *free*, who is out of prison; and a bird is *free*, when let out of the cage: *free* from pain, i. e. void of pain; we say, a *free* air, a *free* passage, &c.

FREE, in speaking of things endowed with understanding, has a more peculiar relation to the will, and implies its being at full liberty.

The Stoics maintain, that their sage or wise men alone are *free*.

FREE is also used in opposition to slave.

The moment a slave sets foot on English ground, he becomes to some purposes *free*. The chief legacy the ancient Romans could leave their slaves, was their *freedom*.

FREE, *shoot a ship*. The seamen say the pump *frees* the ship, when it throws out more water than leaks into her; but, on the contrary, when it cannot throw out the water as fast as it leaks in, they say the pump cannot *free* her: also bailing or lading out water out of a boat, is called *freeing* the boat.

FREE *agent*. See AGENT.

FREE *bench*, or *franc banc*, signifies that estate in copyhold lands, which the wife hath after the decease of her husband, for her dower, according to the custom of the manor.

Fitzherbert calls *free bank* a custom, whereby, in certain cities, the wife shall have her husband's whole lands, &c. for her dower.

Thus, at Okleton, in the county of Hereford, the relict of a copyhold tenant is admitted to her *free bench*, i. e. to all her husband's copy hold land, during her life, at the next court after her husband's death.

In the manors of East and West Enborne, in Berks, if a customary tenant die, the widow shall have a *free bench* in all his copyhold lands, only *dum sola & casta fuerit*: if she commits incontinency, she forfeits her estate; but if she will come into court, riding backwards on a black ram, with his tail in her hand, rehearsing a certain form of words, in the nature of a confession and petition, the steward is bound by the custom to restore to her her *free bench*. The words are these:

Here I am
Riding upon a black ram,
Like a whore as I am;
And for my crincum crancum
I have lost my dicum dancum,
And for my tail's game
Have done this wordily shame;
Therefore, pray, Mr. Steward, let me have my land again.

The like customs hold also in the manor of Chadleworth, in Berks; that of Tor, in Devonshire; and in some other parts of the West.

FREE-

FREE-*hooter*, or FLIBUSTER, a name given to the pirates, who scour the American seas; particularly such as make war against the Spaniards.

The French call them *flibustiers*, deducing the word from the English *fibote*, or *fyboter*; by reason the firſt adventurers of this kind were the people of St. Domingo, who made their excurſions with fybotes, which they had taken from the Engliſh. See BUCCANEER.

FREE *bord*, *franc bord*. In ſome places three feet, in others more, and in others leſs, is claimed by way of *free bord*, beyond or without the fence.

Et etiam boscum, quod vocatur brendewode, *cum franc bordo duorum pedum, & dimidii per circuitum illius bosci.* Mon. Ang. 2d part, fol. 241.

FREE-*chapel*, is a chapel founded by the king, and by him exempted from the juriſdiction of the ordinary. See CHAPEL.

A ſubject may alſo be licenſed by the king to build ſuch a chapel, and by his charter may exempt it from the viſitation of the biſhop, &c.

FREE or *imperial cities* in Germany, are thoſe not ſubject to any particular prince; but governed, like republics, by their own magiſtrates.

There were *free cities, liberæ civitates*, even under the ancient Roman empire: ſuch were thoſe to whom the emperor, by the advice or conſent of the ſenate, gave the privilege of appointing their own magiſtrates, and governing themſelves by their own laws. See CITY.

FREE *fair*. See FAIR.

FREE *fee*. See FEE and FRANK.

FREE-*mason*. See MASON.

FREE *port*. See PORT.

FREE *ſtate*, is a republic governed by magiſtrates, elected by the *free* ſuffrages of the inhabitants.

FREE-*ſtone*, a whitiſh ſtone, dug up in many parts of England, that works like alabaſter; but is more hard and durable, being of excellent uſe in building, &c.

It is a kind of the grit ſtone, but finer landed, and a ſmoother ſtone; and is called *free ſtone*, from its being of ſuch a conſtitution as to be cut freely in any direction.

This is a ſpecies of the PSAMMITES of Hill.

The qualities of the ſeveral kinds of *free ſtone*, in common uſe in the ſeveral parts of Europe, are very different. They all agree in this general property indeed, that they are ſofter while in the quarry than when they have been ſome time expoſed to the air; but even this general property differs greatly in degree. They have a ſort of grey *free ſtone* in uſe at Paris, of which we do not ſeem yet to have met with any quarries in England, though probably enough there are ſuch, which has this property in ſo eminent a degree, that the expence of working it is in a great meaſure ſaved.

This ſtone lies every where on the ſouth ſide of the river Seine, and is of a coarſe and large grain. It is ſo ſoft when newly taken out of the ſtone, that they cut it very conveniently with a ſaw of broad ax-, and faſhion as many ſtones for building in this manner in an hour, as an equal number of our people do in a day or two. Though this ſtone is as ſoft as dry clay when firſt taken up, it is found to harden ſo conſiderably in the air, that it becomes more than equal to our ordinary *freeſtone*.

Our Portland ſtone, of the fineſt kind, which is white, and of a cloſe grit, is very fit for hewing or carving, but it will neither reſiſt water nor fire, which is a very ſingular circumſtance in ſo denſe a ſtone; while the *free ſtone* of Kent, which is leſs beautiful to the eye, and is of a greyiſh colour, and conſiderably cloſe, though of a larger grain, reſiſts the air and water very well.

The *free-ſtone* of Derbyſhire, on the other hand, is ſo brittle as to be unfit for any fine working, and ſo coarſe and open in its texture that it lets water through; yet it bears the fire extremely well, and is fit for ovens, hearths, &c. Phil. Tranſ. N° 93.

FREE-*ſtool*. See FRIDSTOLL.

FREE-*ſubmiſſion*. See DEIST.

FREE-*warren*, the power of granting or denying licence to any one to hunt in ſuch and ſuch ground.

FREE-*will*. See WILL.

FREEDOM, the quality or ſtate of being *free*. See FREE.

FREEDOM *of a city, town*, &c. denotes a right or capacity of exerciſing a certain trade or employment in that city or town corporate, and of being elected to the dignities and offices thereof. It is procured regularly, by ſerving an apprenticeſhip; but ſometimes purchaſed with money, and ſometimes conferred as a favour or compliment.

FREEDOM *of the will*, a ſtate or faculty of the mind, wherein all the motions of our will are in our power, and we are enabled to determine on this or that; to do good or evil, without any force or conſtraint from any external cauſe whatever. See LIBERTY, and NECESSITY.

FREEDOM *of conſcience*. See LIBERTY, and TOLERATION. The ſchoolmen diſtinguiſh two kinds of this *freedom*, viz.

FREEDOM *of contradiction*, whereby we are at our choice to will, or nill; to love, or not to love, &c.

Thus, if I give my friend a power to take my horſe, that friend has *freedom* of contradiction with reſpect to the horſe; ſince it is in his own power either to uſe him, or let him alone.

FREEDOM *of contrariety*, or of *contraries*, is that whereby we are at our choice to do good or evil, to be virtuous or vicious.

Thus, if I offer my friend a horſe, or a lion, and give him his option of the two; he is ſaid to have a *liberty of contrariety* over the horſe and lion.

But the logicians charge this as a faulty or unartful diviſion, in regard one member of the diviſion is contained in the other, as a ſpecies in the genus; for whatever is free, in reſpect of contradiction, is alſo free in reſpect of contrariety, though not vice verſâ: for if it be free for my friend to take the horſe, or the lion, it is alſo free for him to let them both alone; but he may be free to take one of them, without a *freedom* of chuſing which to take.

Yet is the diſtinction of ſome uſe; as it intimates, that the will is not always poſſeſſed of both kinds of *freedom*, and that the matter or ſubject of the two is different.

The will, though it ſhould be allowed to be free, has not a liberty of contrariety: thus, any evident truth being propoſed to the mind, e. g. that the whole is greater than a part, though we may have a power of not aſſenting thereto, by diverting our attention to ſomething elſe, yet we have not a power of diſſenting from that propoſition, and judging that the whole is not greater than the part.

Hence moraliſts commonly hold, that with reſpect to the ſupreme good, mankind has a liberty of contradiction, inaſmuch as he may abſtain from the love or purſuit thereof; but he has not a liberty of contrariety, whereby to hate goodneſs.

Add, that though the human mind may have a *freedom* of contradiction with reſpect to all objects, even the ſupreme good itſelf; yet the *freedom* of contrariety is reſtrained to certain particulars, which either are, or appear to be good; the will having ſuch a natural propenſity to good, that it cannot define evil, but under the notion and appearance of good.

FREEDOM *of thinking*. See DEIST.

FREEHOLD, FRANK TENEMENT, *liberum tenementum*, is land, or tenement, which a man holds in FEE-*ſimple*, FEE-*tail*, or for term of life.

Freehold is of two kinds, in *deed*, and in *law*.

The firſt is the real poſſeſſion of land or tenement in fee, fee-tail, or for life: the other is the right a man has to ſuch land or tenement before his entry or ſeiſure.

A *freehold*, by the common law, cannot commence in *futuro*, but it muſt take effect preſently, either in poſſeſſion, reverſion, or remainder. Whatever is part of the *freehold* goes to the heir; and things fixed thereto may not be taken in diſtreſs for rent, or in execution, &c. No man ſhall be diſſeiſed of his *freehold*, by ſtat. Magna Charta, cap. 29. but by judgment of his peers, or according to the laws of the land: nor ſhall any diſtrain freeholders to anſwer for their *freehold*, in any thing concerning the ſame, without the king's writ. *Freehold* eſtates, of certain value, are required by ſtatutes to qualify jurors, electors of the knights of the ſhire in parliament, &c. For the method of finding the value of *freehold* eſtates, ſee ANNUITIES and LIFE-ANNUITIES.

FREEHOLD is likewiſe extended to ſuch offices as a man holds in FEE, or for life.

FREEHOLD is alſo ſometimes taken in oppoſition to VILLENAGE.

Lambard obſerves, that land, in the Saxons time, was diſtinguiſhed into bocland, i. e. holden by book, or writing; and folkland, held without writing.

The former, he ſays, was held on far better condition, and by the better ſort of tenants, as noblemen and gentlemen; being ſuch as we now call *freehold*: the latter was moſtly in poſſeſſion of peaſants; being the ſame with what we now call *at the will of the lord*.

In the ancient laws of Scotland, *freeholders* are called *milites, barones*. In Reg. Judicial. it is expreſſed, that he who holds land upon an execution of a future recognit, until he hath ſatisfied the debt, *tenet ut liberum tenementum ſibi & aſſignatis ſuis*; and the ſame of a tenant per elegit; the meaning of which ſeems to be, not that ſuch tenants are *freeholders*, but as *freeholders* for the time, till they have received profits to the value of their debt.

FREEZE, or FRIZE, in *Architecture*, that part of the entablature of columns, between the architrave and cornice. See *Tab. Archit. fig.* 24, 25. N° 30, 26, 27, 28.

The *freeze* is properly a large, flat face, or member, ſeparating the architrave from the cornice.

The ancients called it *mutulorum, campum*, because it was usually enriched with figures of animals; and our denomination *freeze* has a like origin, being formed of the Latin *phrygio, an embroiderer*, because it is commonly adorned with sculptures in bass relievo, imitating embroidery.

The *freeze* is supposed to be intended to represent the heads of the transverse beams that sustain the roof or covering.

In the *Tuscan* order it is quite plain; in the Doric, enriched with triglyphs, or channelled figures, with spaces between them, called metopes, which are often plain, and sometimes ornamented; in the Ionic, it is sometimes made arched, or *swelled*, in which case it is called by Vitruvius, *pulvinatus*, q. d. *bolstered*; in the Corinthian and Composite, it is frequently joined to the architrave, by a little sweep, and sometimes to the cornice: and in these richer orders it is usually adorned with sculpture, figures, compartiments, histories, festoons, &c. The *freeze* of the Corinthian order at Palmyra are very richly decorated.

As to the height of the *freeze*, it is in general $\frac{3}{4}$ of that of the architrave; but not strictly or ex. Civ. The Tuscan *freeze*, Vitruvius makes 30 minutes; Vignola, 35; Palladio, who makes it swelling, gives it but 26; and Scamozzi, 42. The Doric, in Vitruvius and Vignola, is 30 or 40 minutes; in Palladio, &c. 45. The Ionic, Vitruvius makes flat, adorned with acanthus leaves, &c. and makes it thirty minutes high: Vignola, who also makes it flat, gives it 45 minutes; and Palladio, who makes it convex, or swelling, 27 minutes; and Scamozzi, 28. The Corinthian, Vitruvius enriches with acanthus leaves, human figures, &c. and makes its height 37 minutes; Vignola, 45; Palladio, 285; and Scamozzi, 315. Lastly, the Composite, which in Vitruvius is set with cantoucres, and carved between them, is 540 minutes; Vignola, who makes it like Vitruvius, only gives it 45 minutes; Palladio, who makes it swelling, only 30; and Scamozzi, 32. See the table under art. COLUMN. From the variety of enrichments practised on the *freezes*, they become variously denominated:

FREEZE, *cushion*, or *pulvinated*, are those whose profile is a curve; the best proportion whereof is, when drawn on the base of an equilateral triangle.

In some, the swelling is only at the top, as in a console; in others at bottom, as in a bolster.

FREEZE, *flourished*, are those enriched with vines, or imaginary foliages, as the Corinthian *freeze* of the frontispiece of Nero, or with natural leaves, either in clusters or garlands; or continued, as in the Ionic of the gallery of Apollo in the Louvre.

FREEZE, *historied*, are those adorned with bass-relievos, representing histories, sacrifices, &c. as that of the arch of Titus at Rome.

FREEZE, *marine*, are those representing sea-horses, tritons, and other attributes of the sea; or shells, baths, grottos, &c.

FREEZE, *rustic*, are those whose courses are rusticated, or imbossed; as the Tuscan *freeze* of Palladio.

FREEZE, *symbolical*, are those adorned with the attributes of religion; as the Corinthian of the temple behind the capitol at Rome, wherein are represented the instruments and apparatus of sacrifice.

FREEZE *of the capital*. See HYPOTRACHELION.

FREEZE, in *Commerce*, a kind of cloth, or fluff. See FRIZE.

FREEZING, *congelation*, in *Physiology*, the fixing of a fluid, or depriving it of its natural mobility, by the action of cold; or it is the act of converting a fluid substance into a firm, coherent, rigid one, called ice.

The Cartesians define *freezing* by the quietude or resting of a fluid body, hardened by cold: which follows naturally enough from their notion of fluidity, where the parts are supposed to be in a continual motion.

In effect, one may pretty safely say, with some of those philosophers, that water *freezes*, because, among other reasons, its parts lose their natural motion, and adhere close to each other.

FREEZING, *the principal phenomena of*, are, 1. That water, and all fluids, oil alone excepted, dilate in *freezing*, i. e. take a more space, and are specifically lighter than before. That the bulk or dimensions of water are increased by *freezing*, is matter of abundant experiment: and here it may be proper to observe the process of nature in this alteration.

A glass vessel, then, B D (*Tab. II. Pneum. fig.* 20.) full of water to G, being immerged in a vessel of water, mixed with salt, R S T V, the water presently rises from F to E; which seems owing to the sudden constriction of the vessel hastily plunged into so cold a medium. Soon after, from the point F it continually descends, condensing, till it arrives at the point G; where, for some time, it seems to remain at rest. But it soon recovers itself, and begins to expand, rising from G to H; and from thence, soon after, by one violent leap, mounts to I. And here the water in B is immediately seen all think and clouds; and in the very instant of this leap, is converted into ice. And, that while the ice is growing harder, and some of the water near the neck of the vessel B is *freezing*, the flux of water is continued above I, towards D, and at length runs out of the vessel.

Mr. Boyle gives us several experiments of vessels made of metals, exceeding thick and strong; in which, when filled with water, close stopped, and exposed to the cold, the water, *in freezing*, coming to be expanded, and not finding either room, or vent, burst the vessels.

A strong barrel of a gun, with water in it, close stopped and *frozen*, was rent the whole length. Happens, in order to try the force with which it would expand itself when confined, filled a cannon, the sides of which were an inch thick, with water, and then closed the mouth and touch-hole, so that none could escape. This instrument thus filled was exposed to a strong *freezing* air. In less than twelve hours the water within was *frozen*, and began to dilate itself with such force, that it actually burst the piece in two different pieces. Mathematicians have calculated the force of the ice upon this occasion; and they say, that such a force would raise a weight of 27,720 pounds; and a small brass vessel, five inches deep, and two in diameter, filled with water, &c. lifted up its lid, which was pressed with a weight of fifty-six pounds.

From hence, therefore, we need not be surprised at the effects of ice in destroying the substance of vegetables and trees, and even splitting rocks, when the frost is carried to excess.

2. That they lose not only of their specific, but also of their absolute gravity, by *freezing*; so that, when thawed again, they are found considerably lighter than they were before.

3. That *frozen* water is not quite so transparent as when liquid; and that bodies do not perspire so freely through it.

4. That water, when *frozen*, evaporates almost as much as when fluid.

5. That water does not *freeze* in vacuo; but necessarily requires the presence and contiguity of the air.

6. That water which has been boiled, *freezes* more readily than that which has not been boiled; and that a slight disturbance of the fluid disposes it to *freeze* more speedily. These two facts have lately been ascertained by the experiments of Dr. Black of Edinburgh. The cause why boiling water accelerates its *freezing*, he supposes to be this; that water which has been boiled has lost the air naturally contained in it, and which, on being exposed to the atmosphere, it begins to attract and absorb. During this process of absorption, which probably continues for a considerable time, a motion is necessarily produced among its particles, which, though imperceptible, may be sufficient to accelerate its congelation. In unboiled water this disturbing cause does not exist. This account is confirmed by a fact mentioned by Fahrenheit, who discovered, that water, when preserved at rest, may be cooled some degrees below the *freezing* point without *freezing*. Having put water, purged of its air, into small glass globes, and sealed them up, he was surprised to find that the water, exposed to a frosty air, remained much longer unfrozen than he expected. Upon opening some of the globes, and admitting the air, a sudden congelation took place, and a similar production of ice was occasioned in the other globes, by shaking them. From this discovery, we are able to understand why they boil the water in India, in order to obtain ice; because the utmost intensity of cold they can obtain is not greater than 91° or 92° of Fahrenheit; but common water may easily be cooled to this degree, provided it be undisturbed, without *freezing*; whereas this cannot happen to boiled water. Phil. Transf. vol. lxv. part i. art. 13.

7. That the water, being covered over with a surface of oil of cloves, does not *freeze* so readily as without it; and that nut-oil absolutely preserves it under a strong frost, when olive-oil would not.

8. That rectified spirit of wine, nut-oil, and oil of turpentine, seldom *freeze*.

9. That the surface of the water in *freezing*, appears all wrinkled; the rugæ, or wrinkles, being sometimes in parallel lines, and sometimes like rays, proceeding from a centre to the circumference.

FREEZING, *the theories of*, or the methods of accounting for these phenomena, are very numerous. The great principles different authors have gone upon, are either, that some foreign matter is introduced within the pores of the fluid, by whose means it is fixed, its bulk increased, &c.

Or, that some matter naturally contained in the fluid, is now expelled; by the absence whereof the body becomes fixed, &c.

Or,

Or, that there is some alteration produced in the texture or form, either of the particles of the fluid itself, or of something contained within it.

To some one of these principles all the systems of *freezing* are reducible.

The Cartesians, who ascribe all to the quietude of the parts of the fluid, before in motion, account for *freezing* from the recess of the ethereal matter out of the pores of the water. The activity of that ether, or subtle matter, they hold to be that which gave the particles of the fluid their motion; consequently, upon the absence of this matter, the fluidity must cease.

Though others of the same sect ascribe *freezing* to a diminution of the usual force and efficacy of the ethereal matter, occasioned by an alteration in the temperature of the air, whereby it is incapacitated for agitating the parts of the fluid as usual.

The Gassendists, and other Corpuscularians, with more probability, ascribe the *freezing* of water to the ingress of a multitude of cold or frigorific particles, which, entering the liquor in swarms, and dispersing themselves every way through it, crowd into the minutest parts of the water, and hinder the wonted agitation of its parts, wedging it up, as it were, into the hard and consistent body of ice. And hence its increase of dimensions, coldness, &c.

This intromission of a foreign frigorific matter they suppose essential to CONGELATION, as that which characterizes and distinguishes it from COAGULATION; the latter being effected indifferently by a hot or cold mixture, but the former only by a cold one.

Of what kind these frigorific particles are, or how they produce their effect, is matter of debate, and has given occasion to various systems.

Hobbes will have them to be common air, which, intruding into the water in congelation, entangles itself with the particles of the fluid, prevents their motion, and produces those numerous bubbles observed in ice; thus expanding its bulk, and rendering it specifically lighter: but this opinion is overturned by Mr. Boyle, who shews, that water will freeze in vessels hermetically sealed, and into which the air can have no ingress; and yet the bubbles will be as numerous herein as in that frozen in the open air. Add, that oil is condensed in *freezing*; consequently, the air cannot there be the cause.

Others, of whom there is the greatest number, will have the *freezing* matter to be a salt; arguing, that an excess of cold will render water torpid, but can never congeal it, without salt. They are saline particles, say they, and those dissolved and mixed in a due proportion, that are the chief cause of *freezing*, congelation bearing a near relation to CRYSTALLIZATION.

This salt they suppose of the nitrous kind, and to be furnished by the air, which is generally allowed to abound in nitre. See AIR, and NITRE.

How the particles of nitre may prevent the fluidity of water, is pretty easily accounted for: these particles are supposed to be so many rigid, pointed spicula, which are easily driven into the stamina, or globules, of the water, and thus becoming variously mingled and entangled therewith, by degrees enfeeble and destroy the motion thereof. The reason this effect only arises in severe winter weather is, that it is then only that the retarding action of the nitrous spicula is more than equal to the power, or principle, whereby the fluid is otherwise kept in motion, or disposed for motion.

This opinion is supported by the known experiment of artificial *freezing*. See FREEZING *mixture*. Let a quantity of common salt, or salt-petre, be mixed with snow, or ice pulverized, and the mixture dissolved by the fire; upon immerging a tube full of water in the solution, the water, or at least that part of it next the mixture, presently freezes, even in warm air. Whence it is imagined, that the spicula of the salt, by the gravity of the mixture, and of the incumbent air, are driven through the pores of the glass, and mixed with the water; for that it is the salt has the effect, is supposed evident; inasmuch as we know, assuredly, that the particles of water cannot find their way through the pores of glass. In these artificial *freezings*, whatever part the mixture is applied in, there is presently produced a skin, or lamina, of ice, whether at top, or bottom, or on the sides; because there is always a stock of saline corpuscles sufficient to overpower the corpuscles of fire; but natural congelations are confined to the top of the water, where the salt most abounds.

Against this system the author of the Nouvelle Conjecture pour expliquer la Nature de la Glace, objects, that it does not appear, that nitre always enters the composition of ice; but that if it did, it would come short of accounting for some of the principal effects. For how, for instance, should the particles of nitre, by entering the pores of water, and fixing the parts, oblige the water to dilate, and render it specifically lighter? Naturally they should augment its weight. This difficulty, with some others, evince the necessity of a new theory. That author, therefore, advances the following one, which seems to solve the phenomena in a more easy and simple manner; as not depending on the precarious admission, or extrusion, of any heterogeneous matter.

Water, then, *freezes* in the winter only, because its parts, being then more closely joined together, mutually embarrass one another, and lose all the motion they had; and the cause of this closer union of the water, is the air; or, more expressly, an alteration in the spring and force of the air.

That there is an infinite number of particles of gross air interspersed among the globules of water, is abundantly evident from experiment; and that each particle of air had the virtue of a spring, is confessed: now this author argues, that the small springs of gross air, mixed with the water, have more force in cold winter weather, and unbend themselves more, than at other times: hence those springs, thus unbending themselves on one side, and the external air continuing to press the surface of the water on the other, the particles of water, thus constringed and locked up together, must lose their motion and fluidity, and form a hard consistent body; till a relaxation of the spring of the air, from an increase of heat, reduces the particles to their old dimensions, and leaves room for the globules to flow again.

But this system has its foible; even the principle on which it stands, may be demonstrated to be false. The spring, or elasticity of the air, is not increased by cold, but diminished. Air expands itself by heat, and condenses by cold; and it is demonstrated in pneumatics that the elastic force of expanded air, is to that of the same air condensed, as its bulk, when rarefied, to its bulk condensed.

It is scarce worth mentioning, that some authors have advanced, to account for the increase of bulk and diminution of specific gravity of frozen water, that the aqueous particles in their natural state were nearly cubes, and so filled that space without the interposition of many pores; but that, by congelation, they are changed from cubes to spheres; whence a necessity of much empty space between them. Cubic particles are certainly much less proper to constitute a fluid, than spherical ones; and spherical particles, less disposed to form a fixt, than cubic ones. Thus much the nature of fluidity and firmness easily suggests. For a consistent theory of *freezing*, we must recur either to the frigorific matter of the Corpuscularians, considered under the light and advantages of the Newtonian philosophy; or to the ethereal matter of the Cartesians, under the improvements of Mons. Gauteron, in the Memoires de l'Academie Royale des Sciences, an. 1709.

Each of which we shall here subjoin; and leave the reader to make his choice. For the first: a number of cold saline corpuscles, being introduced into the interstices between the globules of water, may be so near each other, as to be within the sphere of one another's attraction; the consequence of which must be, that they will cohere into one solid or firm body; till heat afterwards, separating them, and putting them into various motions, breaks this union, and separates the particles so far from one another, that they get out of the distance of the attracting force; and into the verge of the repelling force; and then the water reassumes its fluid form.

For that cold and *freezing* do arise from some substance of a saline nature, floating in the air, seems probable, hence, that all salts, and more eminently some particular ones, when mixed with snow, or ice, do prodigiously increase the force and effects of cold: add, that all saline bodies do produce a stiffness and rigidity in the parts of those bodies into which they enter.

Microscopical observations upon salts manifest, that the figures of some salts, before they shoot into masses, are thin, double, wedge-like particles, which have abundance of surface with respect to their solidity (the reason why they swim in water when once raised in it, though specifically heavier); these small points of the salt getting into the pores of the water, whereby, also, they are in some measure suspended in the winter-time (when the heat of the sun is not strong enough to dissolve the salts into a fluid, to break their points, or to keep them in perpetual motion), being less disturbed, and more at liberty to approach one another: and, by shooting into crystals of the form above mentioned, do, by their extremities, insinuate themselves into the minutest pores of the water, and, by that means, *freeze* it into a solid form.

Farther, there are many little volumes, or particles, of air, included at several distances, both in the pores of the watery particles, and in the interstices left by the spheri-

tal figures. By the infinuation of the faline cryſtals, the volumes of air are driven out of the watery particles, and many of them uniting, form larger volumes, which thereby have a greater force to expand themſelves than when diſperſed; and ſo both enlarge the dimenſions, and leſſen the ſpecific gravity of the water, thus congealed into ice.

Hence, alſo, we may conceive how water, impregnated with ſalts, ſulphurs, or earths, which are not eaſily diſſolvable, may form itſelf into metals, minerals, bitumens, and other foſſils; the parts of theſe mixtures becoming a cement to the particles of water; or, getting into their pores, change them into theſe different ſubſtances.

For the ſecond: as an æthereal matter, or medium, is generally allowed the cauſe of the motion of fluids; and as the air itſelf has all its motion from the ſame principle; it follows that all fluids muſt remain in a ſtate of reſt, or fixity, when this matter loſes of its neceſſary force: of conſequence, the air, being leſs warmed in the winter-time, from the obliquity of the rays of the ſun, is denſer, and more fixed, in winter, than any other ſeaſon of the year.

But, farther, from divers experiments we have learned, that the air contains a ſalt, ſuppoſed to be of the nature of nitre: this granted, and the denſity of the air allowed, it follows, that the molecules of this nitre muſt likewiſe be brought nearer together, and thickened, by the condenſation of the air; as, on the contrary, a rarefaction of the air, and an augmentation of its fluidity, muſt divide and ſeparate them.

If, now, the ſame thing happen to all liquors that have imbibed or diſſolved any ſalt: if the warmth of the liquid keep the ſalt exactly divided; and if the coolneſs of a cellar, or of ice, give occaſion to the molecules of the diſſolved ſalt to approach, run into each other, and ſhoot into cryſtals; why ſhould the air, which is allowed a fluid, be exempt from the general law of fluids?

It is true, the nitre, or the air, being groſſer in cold weather than hot, muſt have leſs velocity; but ſtill the product of its augmented maſs, into the velocity remaining, will give it a greater momentum, or quantity of motion; nor is any thing farther required to make this ſalt act with greater force againſt the parts of fluids; and, probably, this is the cauſe of the great evaporation in froſty weather.

This aerial nitre muſt promote the concretion of liquids; for it is not the air, nor yet the nitre it contains, that gives the motion to fluids; it is the ethereal medium. From a diminution of the force of that, therefore, ariſes a diminution of the motion of the reſt.

Now the ethereal matter being weak enough of itſelf, in the winter-time, muſt loſe ſtill more of its force by its action againſt air condenſed, and loaded with large molecules of ſalt: it muſt, therefore, loſe of its force in cold weather, and become leſs diſpoſed to maintain the motion of fluids. In a word, the air, during froſt, may be eſteemed like the ice impregnated with ſalt, wherewith we ice our liquors in ſummer time. Thoſe liquors, in all probability, *freeze*, from a diminution of the motion of the ethereal medium, by its acting againſt the ice and ſalt together; and the air, for all its ſcorching heat, is not able to prevent its concretion.

FREEZING *mixture*, a preparation for the artificial congelation of water and other liquors.

All kinds of ſalts, whether alcaliſate or acid; and even all ſpirits, as thoſe of wines, &c. as alſo ſugar, and ſaccharum Saturni, mixed with ſnow, are capable of *freezing* moſt fluids; and the ſame effect is produced, in a very great degree, by a mixtion of oil of vitriol, or ſpirit of nitre, with ſnow. Thus Mr. Boyle.

M. Homberg obſerves the ſame of equal quantities of corroſive ſublimate, and ſal ammoniac, with four times the quantity of diſtilled vinegar.

Boerhaave gives us a method of producing artificial froſt, without either ſnow or ice: we muſt have for this purpoſe, at any ſeaſon of the year, the coldeſt water that can be procured; this is to be mixed with a proper quantity of any ſalt (ſal ammoniac will anſwer the intention beſt), at the rate of about three ounces to a quart of water. Another quart of water muſt be prepared in the ſame manner with the firſt; the ſalt, by being diſſolved in each, will make the water much colder than it was before. They are then to be mixed together, and this will make them colder ſtill. Two quarts more of water prepared and mixed in the ſame manner are to be mixed with theſe, which will increaſe the cold to a much higher degree in all. The whole of this operation is to be carried on in a cold cellar; and a glaſs of common water is then to be placed in the veſſel of liquor thus artificially cooled, and it will be turned into ice in the ſpace of twelve hours.

There is a method of making artificial ice by means of ſnow, without any kind of ſalt: for this purpoſe fill a ſmall pewter diſh with water, and upon that place a common pewter plate filled, but not heaped, with ſnow. Bring this ſimple apparatus near the fire, and ſtir the ſnow in the plate: the ſnow will diſſolve, and the ice will be formed on the back of the plate, which was hot in the diſh of water.

Nothing is more commonly known than the method of congealing liquors into ice by an artificial froſt, even in the warmeſt ſeaſon; but it does not ſeem to be yet known what are the ſalts moſt efficacious of all on this occaſion, or, in other words, what ſalt is capable of producing the greateſt degree of artificial cold, or in what manner it may be beſt uſed, and what proportion it ought to bear with the powdered ice or ſnow that is uſed on the occaſion. The common proceſſes are known, but few have enquired ſo curiouſly into the whole as to make a ſubject ſeems to deſerve.

Mr. Reaumur at length took the whole into conſideration, and examined the various degrees of cold by a nice thermometer, which being placed in the liquor to be frozen, ſhewed very exactly the degree of cold by the deſcent of the ſpirit.

Salt-petre uſually paſſes for a ſalt that may be very ſerviceable in theſe artificial congelations; but the experiments of this gentleman prove, that this is an erroneous opinion. The moſt perfectly refined ſalt-petre employed in the operation ſunk the ſpirit in the thermometer but three degrees and a half below the fixed point.

Of the ſalt-petre he uſed, the unrefined makes the ſpirit ſink conſiderably lower; the cauſe of which is, that the rough ſalt-petre contains a large quantity of common, or ſea ſalt; and this being able to cauſe a greater degree of cold than the ſalt it is mixed with, exerts itſelf with it, and carries it to a greater degree of coldneſs; whereas in the refining ſalt petre, this ſea ſalt is thrown out, and conſequently the nitre becoming purer, acts only on its own principle, and cauſes a leſs degree of cold, ſuch as is its appropriated one.

Two parts of common ſalt being mixed with three parts of powdered ice in very hot weather, the ſpirit in the thermometer immediately deſcended ſixteen degrees, which is half a degree lower than it would have deſcended in the ſevereſt cold of the year 1709. Mr. Reaumur after this experimented the ſalts all round, and tried with great regularity and exactneſs, what was the degree of cold occaſioned by each in a given doſe. Among the neutral ſalts, none produced a greater degree of cold than the common ſea ſalt. Among the alkalies, ſal ammoniac, though generally eſteemed in very powerful a one on theſe occaſions, ſunk the thermometer only to thirteen degrees. Pot-aſhes ſunk it juſt as low as well refined ſalt-petre. Thus by trials of the ſeveral ſalts, the proper degree of cold producible from each is eaſily aſcertained, and tables may be made of the numbers. After which, in the deſcribing any degree of cold in a particular ſeaſon, it will be a much better way of expreſſing it, to ſay, it was equal to that produced by ſuch or ſuch a ſalt, than to name it by the degrees of a thermometer.

For the common uſes of the table, the ice required is not expected to be very hard, or ſuch as is produced by long continuance of violent cold: it is rather deſired to be like ſnow. Salt-petre, which is no very powerful *freezer*, is therefore more fit for the purpoſe than a more potent ſalt. It is not required that the congelations ſhould be very ſuddenly made, but its retaining its form as long as may be when made, is a thing of great importance to the dealer in theſe things; nor is the price of the ſalts which are to be uſed for this purpoſe, a matter of indifference.

If it be deſired to have ices very hard and firm, and very ſuddenly prepared, then ſea ſalt is of all others moſt to be choſen for the operation. The ices thus made will be very hard, but they will keep only a very little time without running. Pot-aſhes afford an ice of about the hardneſs that is uſually required. This forms indeed very ſlowly, but then it will preſerve itſelf a long time. And there is another ſubſtance which performs the buſineſs very nearly in the ſame manner with the pot-aſhes, and that on the ſame principle. This is a very cheap and ſimple one, being no other than common wood aſhes; but for this purpoſe the wood, which is burnt, muſt be freſh.

The ſtrong acid ſpirits of the neutral ſalts act much more powerfully in theſe congelations than the ſalts themſelves, or indeed than any ſimple ſalt can do. Thus ſpirit of nitre mixed with twice its quantity of powdered ice, immediately ſinks the ſpirit in the thermometer to nineteen degrees; that is, it produced a cold of four degrees greater than that obtained by means of

sea salt, the most powerful of all the salts in making artificial cold. A much greater degree of cold may be given to this mixture by piling it round with more ice mixed with sea salt. This gives a redoubled cold, and on the trial the thermometer was known to sink to twenty-four degrees; that is, a degree of cold was thus artificially produced, which was to the greatest known natural cold, that of the severe winter in 1709, as twelve to seven, or thereabouts. If this whole matter be covered with a fresh mixture of spirit of nitre and ice, yet a greater degree of cold is produced, and so on; the cold being by this method of fresh additions to be increased almost without bounds: but every addition, it is observed, gives a smaller increase than the former.

It is very remarkable in the acid spirits, that though sea salt is so much more powerful than nitre in substance in creating cold, yet the spirit of nitre is much stronger than that of sea salt; and another not less wonderful phenomenon is, that spirit of wine, a liquor which is little other than a liquid fire, has as powerful an effect in congelations, or very nearly so, as the spirit of nitre itself. What but experiment could have brought people to imagine, that these two so very different liquors could have this property as it were in common?

The mixture of any other matter with powdered ice does not create a new cold by any other means than that of melting the ice it is mixed with. The moment of that melting is therefore the point of time in which the cold is strongest of all, as after that the warmth of the external air, cannot but be continually taking off from the new engendered cold. It is plain from hence, that the quicker this melting is performed, the harder the ice melts, or the greater degree of cold. It were much to be wished therefore, that the melting could be instantaneous, as in that case the particles of ice would all act at one and the same time on the matter to be congealed: and in order to this, it is necessary that every particle of ice should have a particle of salt ready to act upon it. This requires that the ice and the salt should be both powdered to a certain fineness. Hence may be deduced a rule, which, though not quite so precise, yet may be sufficiently so for the determining the proper proportion of the salt to be mixed with any determinate quantity of ice. We well know from experiment, how large a quantity of water is necessary to melt a certain quantity of salt of any kind, and repeated experiments might bring the knowledge of the other solution to nearly as great a certainty. It would be well to try the whole carefully with sea salt: and when the proportions of this were known, it would be no difficult matter from these to deduce the proper quantities of other salts, according to their known differences, in regard to the quantities of water necessary to dissolve them.

The several liquid substances which create a cold, in the same manner as the dry salts on being mixed with ice, are much more speedy in their action than the salts; because they immediately and much more intimately come into contact with the particles of the ice, than the salts can. Of this nature are spirit of nitre, spirit of wine, &c. to produce the expected degree of cold, it is always necessary that the ice and the added matter, whatever it be, should both run together and intimately uniting form one clear fluid; it is hence that no new cold is produced with oil, which, though it melts the ice, yet cannot mix itself into a homogene liquor with it, but must always remain floating on the surface of the water, produced by the melting of the ice. Mem. Acad. Scienc. Par. 1734.

Of late there has been a more effectual method of congealing fluids than any yet recited. It has been discovered, that fluids standing in a current of air, grow by this means much colder than before. Fahrenheit had long since informed us, that a pond, which stands quite calm, often acquires a degree of cold much beyond what is sufficient for *freezing*, and yet no congelation ensued: but if a slight breath of air happens in such a case to brush over the surface of the water, it stiffens the whole in an instant. However, a phenomenon attends this experiment, which has not yet been explained; for the water, before its congelation, and in its liquid state, sinks the thermometer very low, which shews its excessive degree of coldness; but as soon as it begins to congeal by means of the air, or any other agitation, the thermometer rises to the ordinary *freezing* point. It has been discovered also, that all substances grow colder by the EVAPORATION of the fluids which they contain, or with which they are mixed. If both these methods, therefore, are practised upon the same body, at the same time, they will increase the cold to almost any degree of intenseness we desire. The most extraordinary instance of artificial *freezing* that has yet been recorded, is that of the Russian experiments at Petersburgh, in which quicksilver was congealed.

In December 1759, they had at Petersburgh the coldest weather, and the most intense frost that ever was known, so that De Lisle's thermometer stood at 205 degrees: at that time professor Braun repeated Fahrenheit's experiments, in order to produce artificial cold by means of spirit of nitre combined with pounded ice or snow. Aqua fortis, found by the thermometer to be 204 degrees cold, was poured upon pounded ice, both the ice and aqua fortis being of the same temperature with the air; upon the first pouring, the mercury fell 20 degrees; the spirit was poured off and on again several times, but the mercury in the thermometer fell no lower than 234 degrees, so that no more than 30 degrees of cold could by these means be produced; but as Fahrenheit, Reaumur, and Muschenbroek, who had repeated the same experiment, could never produce cold greater than 40° below 0 in Fahrenheit's thermometer, which corresponds with 210 in De Lisle's, used by professor Braun, he satisfied himself with having added 20° to the cold formerly known.

However, he determined to vary his experiments; and being under a necessity of using snow instead of ice, which he afterwards found to be much preferable to it, at a time when the snow and aqua fortis were of the same degree of cold with the air, viz. 203°, he immersed the thermometer in snow contained in a glass; and pouring a few drops of the aqua fortis on that part of the snow in which the thermometer was immersed, he observed the mercury to subside to 260; repeating the experiment in the same manner, and pouring on some more aqua fortis, the mercury immediately fell to 340. And, then, immersing the thermometer, before it had lost any of this acquired cold, in another glass filled with snow, the mercury subsided to 470°. Upon taking out the thermometer the mercury was immoveable, and continued so in the open air for twelve minutes, and did not recover its fluidity and begin to rise for some minutes after it was carried into a warm room, where the temperature of the air was 125°. He repeated the same experiment, first with the same, and then with another thermometer, with the same success. Professor Braun's thermometers had a spherical bulb, and their scale was divided into 1200 parts, of which 600 were above 0, which denotes the heat of boiling water, and 600 below that heat. He also used another thermometer, the scale of which went no lower than 360° below 0, denoting the heat of boiling water. The mercury stood descended in this thermometer, so that the whole was contained in the bulb; and the immobility of the mercury led him to conjecture, that it might be frozen or become a solid body. But as he had not broken his glasses, he could at that time only form a conjecture. At another time, when the cold was abated, and the thermometer stood at 199°, he repeated the experiment with a little variation: he first put the bulb of the thermometer into a glass of snow, gently pressed down, before he poured on the aqua fortis; he then, in another glass, poured the aqua fortis upon the snow, before he immersed the thermometer in it; and he also put the snow to the aqua fortis, before he put his thermometer in it: but in these several ways he found the event exactly the same; the mercury was immoveable; and breaking the bulb of the thermometer, he found the mercury solid, but not wholly so, as the middle part of the sphere was not yet fixed. Mr. Æpinus repeated the same experiment, and the mercury in his thermometer fell with extreme rapidity, almost to the 500th degree; and in breaking the glass from below, he found the quicksilver contained in it absolutely frozen. The quicksilver, thus rendered solid, bore hammering and extension, like other metals; its hardness was like that of lead, though somewhat softer; and, upon striking, it sounded like lead. When the mercury was extended by these strokes, it was easily cut with a penknife, and, in its congealed state, looked like the most polished silver; but in about twelve minutes, after being exposed to the air, which was 197°, it recovered its former fluidity. In this last experiment of Mr. Braun, the mercury descended to 530°, and on the next day, the cold having increased to 112°, it descended to 650. In his following experiments, he invariably found, that the mercury sunk lower, when the whole of it was congealed than if any part of it remained fluid. It then generally descended to 680 and 700, but the bulbs were never in any of his experiments, without cracks: moreover, the mercury, on other occasions, descended to 800, and even to 1500; but, in this last experiment, the bulb was quite broke, so that the globe of mercury, thoroughly frozen, fell out, and by its fall, of about three feet, the ball of mercury became a little compressed. In another experiment, when the mercury descended to 1260°,

126°, the congealed ball was ſtruck ſeveral times with an ax, and became flat like an Engliſh half-crown; but receiving ſome cracks by the blows, it diſſolved in about twenty minutes.

Mr. Braun found, that, *ceteris paribus*, the more intenſe the natural cold was, the more eaſily and expeditiouſly did theſe experiments ſucceed; though with the nitrous acid poured on ſnow, mercury may be congealed at any time, when the heat of the atmoſphere is not greater than 75° by De Lille's thermometer: and though the degree of cold neceſſary to conſolidate mercury cannot be preciſely aſcertained, yet Mr. Braun eſtimates it to be about 460 degrees in his thermometer. In the proceſs of his obſervations, Mr. Braun found that double aqua fortis was more effectual than ſpirit of nitre; but with the ſimple ſpirit of nitre, which ſeldom brings the mercury lower than 300°, mercury may be frozen in the following manner: let ſix glaſſes be filled with ſnow as uſual, and the thermometer be put in one of them, and the ſpirit of nitre be poured upon it; when the mercury will fall no lower in this, remove the thermometer to the ſecond, and ſo on to the third and fourth, in which fourth immerſion the mercury was congealed. Mr. Æpinus gives the following direction for uſing the fuming ſpirit of nitre: take the ſpirit of nitre, cooled as much as poſſible, and with it fill half a wine-glaſs, throwing in as much ſnow at the ſame time, and ſtirring it till it becomes of the conſiſtence of pap; and you thus obtain, almoſt in an inſtant, the neceſſary degree of cold for the congelation of quickſilver. In the experiments above recited, diſtilled quickſilver was generally uſed; and in ſome the quickſilver was revivified from ſublimation.

It is remarked by Mr. Braun, that by the mixture of ſnow and ſpirit of nitre, which froze the mercury, he never was able to bring thermometers, filled with the moſt highly rectified ſpirit of wine, lower than 300°: ſo that the cold which will freeze mercury, will not freeze ſpirit of wine; and therefore ſpirit thermometers are the moſt fit to determine the degree of coldneſs in frigorific mixtures, till we are able to conſtruct ſolid metallic thermometers with ſufficient accuracy. Mr. Braun tried the effects of different fluids in his frigorific mixtures: he always found that Glauber's ſpirit of nitre and double aqua fortis were the moſt powerful; and from a number of experiments made when the temperature of the air was between 159 and 153 by his thermometer, he concludes, that ſpirit of ſalt pounded upon ſnow, increaſed the natural cold 30°; ſpirit of ſal ammoniac, 10; oil of vitriol, 35; Glauber's ſpirit of nitre, 58; aqua fortis, 40; ſimple ſpirit of nitre, 30; dulciſied ſpirit of vitriol, 20; Hoffman's anodyne liquor, 32; ſpirit of hartſhorn, 10; ſpirit of ſalpher, 10; ſpirit of wine rectified, 20; camphorated ſpirit, 25; French brandy, 123 and ſeveral kinds of wine increaſed the natural cold to 6, 7, or 8 degrees. It appears alſo, from Mr. Braun's experiments, that both the boiling and *freezing* of mercury have this in common; that, when it begins to boil, it riſes with rapidity, and deſcends rapidly when it begins to freeze: ſo that if the mean term of the congelation of mercury be fixed at 650 below 0, and the term of its boiling at 414 above 0, its greateſt contraction to its greateſt dilatation will be 1064 degrees of Mr. Braun's thermometer, and 1237 of Fahrenheit's, as 212 is the point of boiling water, and 32 the *freezing* point in Fahrenheit's, which correſponds with 150 under the term of boiling water in Mr. Braun's. Hence every one will ſee the great alteration of ſpecific gravity in frozen and boiling mercury, as, between one and the other, the tenth part of the volume is leſſened. Phil. Tranſ. vol. li. part ii. for 1760. art. 64. p. 672. Ibid. vol. lii. part i. art. 31. p. 150. See alſo an account of ſome ſucceſsful experiments for *freezing* quickſilver at Albany fort, Hudſon's bay, in 1775, by Mr. Hutchins, Phil. Tranſ. vol. lxvi. part i. art. 10. p. 174. See MERCURY and THERMOMETER.

FREEZING *rain*, or *raining ice*, a very uncommon kind of ſhower, which fell, in the Weſt of England, in December, anno 1672. See Phil. Tranſ. N° 90.

This rain, as ſoon as it touched any thing above ground, as a bough, or the like, immediately ſettled into ice; and, by multiplying and enlarging the icicles, it broke all down with its weight. The rain that fell on the ſnow, immediately *froze* into ice, without ſinking in the ſnow at all.

It made an incredible deſtruction of trees, beyond any thing in all hiſtory. "Had it concluded with ſome guſt "of wind," ſays a gentleman on the ſpot, "it might "have been of terrible conſequence."

"The ſprig of an aſh-tree, of juſt three quarters of a "pound, being weighed, the ice thereon weighed ſix-"teen pounds. Some were frighted with the noiſe "in the air; till they diſcerned it was the clatter of icy "boughs daſhed againſt each other." Dr. Beale obſerves, that there was no conſiderable froſt obſerved on the ground during the whole; whence he concludes, that a froſt may be very fierce, and dangerous, on the tops of ſome hills: while, in other places, it keeps at two, three, or four, feet diſtance above the ground, rivers, lakes, &c. and may wander about, very furiouſly, in ſome places, and be remiſs in others, not far off. This froſt was followed by glowing heats, and a wonderful forwardneſs of vegetation.

FREEZING *of wines*. See *Condenſing of* WINES.

FREEZING, in *Commerce* and *Manufactures*. See FRIZING.

FREEZING, in *Sea Language*, is a ſort of ornamental painting on the upper part of a ſhip's quarter, ſtern, or bow. It generally conſiſts of armour, inſtruments of war, marine emblems, &c.

FREEZELAND, FRIEZELAND, or FRIZELAND, *baſe*, in *War*, the ſame with CHEVAL *de friſe*.

FREGAROLA, *in Ichthyology*, a name given by many to a ſmall river-fiſh, well known in England by the name of the MINOW.

FREGGIA, in *Ichthyology*, the name of a long anguilliform fiſh of the tenia kind, more commonly called CAVAGIRO.

FREGIT *clauſum*. See CLAUSUM.

FREIGHT. See FRAIGHT.

FREISER, a name uſed by ſome for the STRAWBERRY *plant*.

FRENCH, FRANÇOIS, abſolutely uſed, ſignifies the language of the people of France.

The *French*, as it now ſtands, is no original, or mother-language, but a medley of ſeveral: there is ſcarce any language but it has borrowed words, or perhaps phraſes, from.

The languages that prevail moſt, and that are, as it were, the baſis thereof, are, 1. The Celtic; whether that were a particular language itſelf, or whether it were only a dialect of the Gothic, as ſpoke in the Weſt and North. 2. The Latin, which the Romans carried with them into the Gauls, when they made the conqueſt thereof. And, 3. The Teutonic, or that dialect of the Teutonic ſpoke by the Franks, when they paſſed the Rhine, and eſtabliſhed themſelves in Gaul.

Of theſe three languages, in the ſpace of about thirteen hundred years, was the preſent *French* formed, ſuch as it is now found. Its progreſs was very ſlow; and both the Italian and Spaniſh were regular languages long before the *French*.

Paſquier obſerves, it was under Philip de Valois, that the *French* tongue firſt began to be poliſhed; and that, in the regiſter of the chamber of accounts of that time, there is a purity ſeen almoſt equal to that of the preſent age. However, the *French* was ſtill a very imperfect language till the reign of Francis I. the cuſtom of ſpeaking Latin at the bar, and of writing the public acts and inſtruments of the courts of juſtice in that language, had made them overlook the *French*, their own language. Add, that the preceding ages had been remarkable for their ignorance, which was owing, in good meaſure, to the long and calamitous wars which France had been engaged in; whence, the *French* nobleſſe deemed it a kind of merit, not to know any thing; and the generals regarded little, whether or no they wrote and talked politely, provided they could but fight well.

But Francis I. who was the reſtorer of learning, and the father of the learned, changed the face of things; and, after his time, Henry Stevens printed his book, De la Precellence du Langage François.

The change was become very conſpicuous at the end of the ſixteenth century; and under Henry IV. Amyot, Coeffeteau, and Malherbe, contributed towards bringing it to its perfection; which the cardinal De Richelieu completed, by the eſtabliſhment of the *French* Academy; an aſſembly, wherein the moſt diſtinguiſhed perſons of the church, the ſword, and the gown, have been members.

Nor did the long reign of Louis XIV. contribute a little to the improvement of the language: the perſonal qualities of that prince, and his taſte for the polite arts, and that of the princes of the blood, rendered his court the politeſt in Europe. Wit and magnificence ſeemed to vie; and his generals might have diſputed with the Greeks, Romans, &c. the glory of writing well, if they could not that of fighting.

From court, the elegance and purity of the language ſoon ſpread itſelf into the provinces; and now there is ſcarce any body there who does not write and ſpeak good *French*. One of the characters of the *French* language is, to be natural and eaſy. The words are ranged in it much in the ſame order as the ideas in our minds; in which it differs exceedingly from the Greek and Latin, where the inverſion of the natural order of words is reputed a beauty. Indeed the Hebrew ſurpaſſes even the *French*

in this point; but then it comes short of it in copiousness and variety.

It must be added, however, that as to the analogy of grammar, and the simplicity wherewith the moods of verbs are formed, the Engliſh has the advantage, not only over the French, but over all the known languages in the world; but then the turns, the expreſſions, and the idioms, of the Engliſh, are ſometimes ſo quaint, and extraordinary, that it loſes a good deal of the advantage which its grammatical ſimplicity gives it over the reſt.

The *French* has but few compound words; whereas it differs widely from the Greek, High Dutch, and Engliſh. This the *French* authors own a great diſadvantage in their language; the Greek and Dutch deriving a great part of their force and energy from the compoſition of words, and frequently expreſſing that in one ſounding word, which the *French* cannot expreſs but by a periphraſis. The diminutives in the *French* are as few as the compounds; the greateſt part of thoſe remaining in uſe having loſt their diminutive ſignification; but what diſtinguiſh the *French* moſt are its juſtneſs, purity, accuracy, and flexibility.

French is the moſt univerſal and extenſive language in Europe. The policy of ſtates and courts has rendered it neceſſary for the miniſters of princes, and their officers, &c. and the taſte of arts and ſciences has had the ſame effect, with regard to the learned.

In Germany, and elſewhere, the princeſſes and perſons of diſtinction value themſelves on underſtanding *French*; and in ſeveral courts of Europe, *French* is almoſt as much known as the language of the country; though the court of Vienna is an exception from this rule. *French* is there very little uſed; the emperor Leopold could not bear to hear it ſpoke in his court; the Latin and Italian are there cultivated inſtead of it. This extenſiveneſs of the *French* language is no modern advantage; William the Conqueror gave laws to England in the *French* language; and the ancient cuſtoms of moſt of the provinces of the Netherlands are wrote in the ſame.

Laſtly, the *French* is the ſame language every where; not only in all the provinces of France, but in all places where it is ſpoken, out of France.

For a critical acquaintance with what regards the *French* tongue, ſee the Remarques of M. Vaugelas; and the Obſervations M. Corneille has made on thoſe remarks; the Remarques of F. Bouhours; and the Doubts of a Bas-Breton gentleman, by the ſame father; the Converſations of Ariſte and Eugene; the Obſervations of M. Menage, and his Etymologies, with thoſe of M. Huet; F. Buffier's French Grammar; and that of the abbé Regnier. Add, the two Diſcourſes of the abbé de Dangeau; one on the vowels, and the other on the conſonants, and many later works.

FRESCO, in the *Arts*, a kind of painting performed on freſh plaiſter, or on a wall laid with mortar not yet dry; and with water-colours.

This ſort of painting has a great advantage; by its incorporating with the mortar, and drying along with it, it is rendered extremely durable; and never falls or falls, but along with it. The Italians, from whom we borrow the term, call it *freſco*; becauſe it is frequently uſed for walls, alcoves, and other buildings, in the *open air*. Vitruvius, lib. vii. cap. 4. calls it *ades teſtorio*.

Painting in *freſco* is very ancient, having been practiſed in the earlieſt ages of Greece and Rome. It is chiefly performed on walls and vaults, newly plaiſtered with lime and ſand; but the plaiſter is only to be laid, in proportion as the painting goes on; no more being to be done at once, than the painter can diſpatch in a day, while it dries.

Before he begins to paint, a cartoon or deſign is uſually made on paper, to be caſked, and tranſferred to the wall, about half an hour after the plaiſter is applied.

The ancients painted on ſtucco; and we may remark in Vitruvius what infinite care they took in making the incruſtation or plaſtering of their buildings to render them beautiful and laſting; though the modern painters find a plaiſter made of lime and ſand preferable to it; both as it does not dry ſo haſtily, and as being a little browniſh, it is fitter to lay colours on, than a ground ſo white as ſtucco.

In this kind of painting, all the compound and artificial colours, and almoſt all the minerals, are ſet aſide, and ſcarce any thing is uſed but earths; which are capable of preſerving their colour, defending it from the burning of the lime, and reſiſting its ſalt, which Vitruvius calls its bitterneſs.

For the work to come out in all its beauty, the colours muſt be laid on quick, while the plaiſter is yet moiſt; nor ſhould they ever be retouched, dry, with colours mixed up with the white of an egg, or ſize, or gum, as ſome workmen do; becauſe ſuch colours grow blackiſh; nor do any preſerve themſelves, but only ſuch as were laid on haſtily at firſt.

The colours uſed, are white made of lime ſlacked long before, and white marble duſt; oker, both red and yellow; verditer; lapis lazuli; ſmalt; black chalk, &c. All which are only ground, and worked up with water; and moſt of them grow brighter and brighter, as the *freſco* dries.

The braſhes and pencils for this work ought to be long and ſoft, otherwiſe they will rake and raiſe the painting. The colours ſhould be full, and flowing from the braſh; and the deſign perfect: for, in this work, you cannot alter or add upon any colour.

FRESH *diſſeiſin*, in *Law*, (*friſca diſſeiſina*, from the French *freis*; i. e. *recent*, & *diſſeiſer*, *viz. poſſeſſione ejicere*) ſignifies that *diſſeiſin* which a man might formerly ſeek to defeat of himſelf, and by his own power, without reſorting to the king or the law: as where it was not above fifteen days old, or ſome other ſhort continuance. Briton, cap. 5. Of this Bracton writes at large, concluding it to be arbitrary. Lib. iv. cap. 5.

FRESH *fine*, is that which was levied within a year paſt. Weſtm. 2. cap. 45. See FINE.

FRESH *force, friſca fortia*, in *Law*, denotes a force done within 40 days.

If a man be diſſeiſed of lands or tenements, within any city or borough; or deforced from them after the death of his anceſtors, to whom he is heir; or after the death of his tenant for life, or in tail; he may, within forty days after his title accrued, have his remedy by an aſſize, or bill of *freſh force*.

FRESH *the houſe*, on board a *Ship*. See HAWSE.

FRESH *Shot*, in the *Sea-phraſe*, ſignifies the falling down of any great river, into the ſea; by means whereof the ſea hath *freſh* water a good way from the mouth of the river. As this is more or leſs, they call it a *great*, or *ſmall freſh ſhot*.

FRESH *Spell*, in the *Sea-language*, a freſh gang, to relieve the rowers in the long boat.

FRESH *Suit, recens inſecutio*, in *Law*, is ſuch a preſent and active proſecution of an offender, where a robbery is committed, as never ceaſes, from the time of the offence committed, or diſcovered, till he be apprehended.

The benefit of ſuch purſuit of a felon is, that the party purſuing ſhall have his goods reſtored to him; whereas otherwiſe they are the king's.

Though the party robbed doth not apprehend the thief immediately, but ſome time after the robbery, provided he uſed his utmoſt endeavours to take him; or though he happens to be apprehended by ſome other perſon, yet it ſhall be adjudged *freſh purſuit*.

Freſh ſuit is either within the view, or without. Manwood ſays, that upon *Freſh ſuit* within the view, treſpaſſes in the foreſt may be attached by the officers purſuing them, though without the limits of the foreſt. *Freſh ſuit* may continue for ſeven years. See HUE *and Cry*.

FRESH *Water*, is that not tinctured or impregnated with ſalt, or ſaline particles, enough to be diſcovered by the ſenſe.

Such generally is that of ſprings, rains, wells, lakes, &c. Dr. Liſter is of opinion, that the natural and original ſtate of water is to be ſalt: the *freſhneſs* he ſuppoſes to be accidental, and to be owing to the vapours of plants, and the breath of animals therein; and to the exhalations raiſed by the ſun.

Others will have all water originally *freſh*, and take its ſaltneſs to be accidental; to account for which, a great number of hypotheſes have been framed.

The ſaltneſs of water is a foreign, and in moſt caſes a hurtful quality. It renders it not only naſeous to the

taſte, but greatly prejudicial to the body; and it is generally agreed, that theſe waters, *caeteris paribus*, are beſt, not only for drinking, but alſo for œconomical uſes, as waſhing, boiling, and brewing, which are the freeſt from ſaltneſs.

Hence various methods have been contrived for examining the *freſhneſs* of waters, and for dulcifying or making ſalt water *freſh*.

Mr. Boyle gives us a method of examining the *freſhneſs* of water, by means of a precipitate, which caſts down any ſaline particles before floating therein.

Into one thouſand grains of diſtilled water he puts one grain of ſalt; and into the ſolution lets fall a few drops of a ſtrong well filtrated ſolution of a well refined ſilver, diſſolved in clear aqua fortis; upon which there immediately appears a whitiſh cloud, which, though but ſlowly, deſcends to the bottom, and there ſettles in a white precipitate, in which is the ſaline matter of the fluid.

This method, if it were required, would examine water to a greater nicety, than that here ſpecified. It has diſcovered ſalt in water where there was but one grain of ſalt in two thouſand, nay in three thouſand times the weight of water.

The experiment was tried before the Royal Society, in 1692, by ſir Hans Sloane; where it was likewiſe found that a drop or two, even of ſpirit of ſalt, mixed with common water would be diſcovered by the ſame method. Phil. Tranſ. abr. vol ii. p. 298.

Dr. Hook, in the ſame year, read a lecture before the Royal Society, on a method of his own, for diſcovering the ſmalleſt quantity of ſalt contained in water, on a principle of hydroſtatics. The operation was performed by means of a large poiſe of glaſs, of the ſhape of a bolt-head; the ball thereof was three inches in diameter, and the neck $\frac{1}{4}$ of an inch. This being ſo poiſed, with red lead put in it, as to make it very little heavier than *freſh* water; and then ſuſpended by the ſmall ſtem, which was graduated, to the end of a nice beam of a balance; and the degree or diviſion of the neck, contiguous to the ſurface of the water, noted; upon infuſing a quantity of ſalt, only equal to the two thouſandth part of the weight of the water, the neck of the poiſe ſunk near half an inch lower in the water. Phil. Tranſ. abr. vol. ii. p. 304.

The dulcifying, or making of ſalt water *freſh*, is a ſecret, that has been long ſought with great attention. For an account of the principal attempts that have been made with this view, ſee *Sea*-WATER.

FRESH *Wind* ſignifies ſtrong, but not violent; hence when the gale increaſes, it is ſaid to freſhen.

FRESHES, in *Sea-language*, denote the impetuoſity of an ebb-tide, increaſed by heavy rains, and flowing out into the ſea, often diſcolouring it to a conſiderable diſtance, and forming a line that ſeparates the two colours, and which may be diſtinctly perceived for a great length along the coaſt.

FRET, or FRETT, in *Architecture*, a kind of knot, or ornament, conſiſting of two liſts, or fillets, variouſly interlaced, or woven, and running at parallel diſtances, equal to their breadth. See *Tab. Archit. fig.* 34.

A neceſſary condition of theſe *frets* is, that every return and interſection be at right angles. This is ſo indiſpenſable, that they have no beauty without it, but become perfectly Gothic.

Sometimes the *frets* conſiſts but of a ſingle fillet, which, if well managed, may be made to fill its ſpace exceedingly well.

The ancients made great uſe of theſe *frets*: the places they were chiefly applied on were even, flat members, or parts of building; as the faces of the corona, and eaves of cornices; under the roofs, ſoffits, &c. on the plinths of baſes, &c.

The appellation was occaſioned hence, that the French word *frette* literally ſignified the timber-work of a roof, which conſiſts chiefly of beams, rafters, &c. laid acroſs each other, and, as it were, *fretted*.

FRET, in *Muſic*, is uſed for the ſtops uſed on ſome inſtruments, eſpecially baſs viols and lutes: it conſiſts of ſtrings tied round the neck of the inſtrument, at certain diſtances, within which ſuch and ſuch notes are to be found. Theſe ſtrings or *frets* are ſometimes, yet ſeldom, put on the baſs violin for learners, and taken off again when they can find the notes without them. On lutes and viols they always remain.

FRET, or FRETTE, in *Heraldry*, is a bearing conſiſting of ſix bars, croſſed, and interlaced, *frenwiſe*; as in *Tab. Herald. fig.* 39.

Guillim derives the word from the French *rets*, *net*; but the reader will eaſily furniſh himſelf with a better etymology from the word *fret*, in architecture.

He bears diamond a *fret* topaz; the coat armour formerly of the lord Maltravers, and now quartered by the duke of Norfolk. When it conſiſts of more than ſix pieces, the number muſt be ſpecified.

Some call this the *true lovers knot*; others *Hungerford's knot*, becauſe it is their arms; and *nodo firmo*, the motto. Gibbon is for calling it *heraldicum nodus amatorius*.

FRETTS, in *Mineralogy*, a term uſed by our miners to expreſs the worn ſide of the banks of the rivers in mine-countries, where they ſearch for the HOAD ſtones, or grewts, waſhed down from the hills, in order from thence to trace out the running of the hoad up to the mine. Phil. Tranſact. N° 69.

FRETTY, or FRETTE, in *Heraldry*, is where there are divers bars laid acroſs each other.

Fretty is of ſix, eight, or more pieces. Azure, *fretty* of eight pieces, or, the coat of the lord Willoughby.

Columbiere obſerves, that *fretty*, abſolutely uſed, without any addition, is ſuppoſed to be of ſix pieces; that is, ſo many bars, or pieces, croſſing each other, which, therefore, need not be expreſſed; but if there be more, as much muſt be mentioned. And yet Guillim has azure, *fretty* of ſix, argent; the coat of the ancient lords Elfingham, of Suſſex.

FRETUM, *ſtraight*, or *ſtreight*, in *Geography*. See STRAIGHT.

FRET-*work*, an enrichment of *frets*, or a place adorned with ſomething in manner thereof. See FRET.

Fret-work is ſometimes uſed, among us, to fill up and enrich flat, empty ſpaces; but it is principally practiſed in roofs, which are *fretted* over with plaiſter-work.

The Italians, alſo, apply it to the mantlings of chimneys with great figures: a cheap piece of magnificence, and as durable almoſt within doors, as harder matters in the weather.

FRIABLE is applied to bodies to denote them tender and brittle, eaſily crumbled or reduced to powder between the fingers; their force of coheſion being ſuch as eaſily expoſes them to ſuch ſolution. Such are pomice, and all calcined ſtones, burnt alum, &c.

Friability is ſuppoſed to ariſe hence, that the body conſiſts wholly of dry parts, irregularly combined, and which are readily ſeparated, as having nothing unctuous or glutinous to bind them together.

FRIAR, or FRIER, by the Latins called *frater*, the Italians *fra*, and the French *frere*, that is, *brother*, is a term common to the monks of all orders; founded on this, that there is a kind of fraternity, or brotherhood, preſumed between the ſeveral religious perſons of the ſame convent or monaſtery.

The kinds of *friars* are very numerous: AUGUSTINE *friars*; DOMINICAN, or black, or preaching, *friars*; FRANCISCAN, or grey, or begging, *friars*; and CARMELITES, or white *friars*.

FRIAR, in a more peculiar ſenſe, is reſtrained to ſuch monks as are not prieſts; for thoſe in orders are uſually dignified with the appellation of FATHER.

FRIARS, or FRIERS *obſervant*, *ſeatres obſervantes*, were a branch of the Franciſcans; thus called, becauſe not combined together in any cloyſter, convent, or corporation, as the conventuals are, but only agreed among themſelves to *obſerve* the rules of their order, and that more ſtrictly than the conventuals did, from whom they ſeparated themſelves out of a ſingularity of zeal, living in certain places of their own chuſing.

FRIAR'S *cotol*, in *Botany*. See WAKE *Robin*.

FRIARY *of the holy Trinity*. See TRINITY.

FRIBURGH, FRITHBURGH, or FRITHEBORG, among our Anglo-Saxon anceſtors, denoted the ſame as FRANK-pledge did after the time of the Conqueſt.

Praeterea eſt quaedam ſumma & maxima ſecuritas, per quam omnes ſtatu ſtrmiſſimo conſtituentur, viz. ut unuſquiſque ſtabiliat ſe ſub fidejuſſione ſecuritatis, quam Angli vocant freoborghes: *ſoli tamen Eboracenſes dicunt eandem* tiendmannatale, *quod ſonat Latine decem hominum numerum.* LL. Edw. II. ap. Lamb.

Every man in this kingdom was anciently aſſociated in ſome decennary, or company of ten families, who were pledged, or bound, for each other, to keep the peace, and obſerve the law. See TITHING. If any offence was done by one, the other nine were to anſwer it; that is, if the criminal fled from juſtice, they had thirty days allowed to apprehend him: if he was not taken in that time, he who was the *friburgh*, i. e. the principal pledge of the ten, ſhould take two of his own number, and the chief pledges of three neighbouring *friburghs*, with two others out of each of the ſaid *friburgh*, who were to purge themſelves, and their *friburgh*, of the forfeiture and flight of the criminal. If they could not do this, the principal pledge, with the other eight, were to make ſatisfaction.

Great men were not combined in any ordinary decenna, or dozen, as being deemed a ſufficient aſſurance for themſelves and their menial ſervants.

FRI-

FRICASSEE, a diſh, or meſs, haſtily dreſſed in a frying-pan, and ſeaſoned with butter, oil, or the like.

The word is French, formed of the Latin *frixatura*, *frying*. Others will have *fricaſſee* formed in imitation of noiſe made by butter, or other fat, when melted in the pan.

We ſay a *fricaſſee* of pullets, of rabbits, of tench, of tripe, of frogs, of eggs, of peas, &c.

FRICHUM, of *frico*, *I rub*, in *Pharmacy*, a name given to ſuch medicines as are intended to be rubbed into the ſeveral parts of the body. The ancients had three kinds of *frichia*, the dry, the ſoft, and the liquid; the firſt was uſed in the way of fumigation, the ſecond was bound on the part with cloths, and the laſt was uſed by way of embrocation.

FRICTION, the act of rubbing or grating the ſurface of one body againſt that of another, called alſo *attrition*.

The phenomena ariſing upon the *friction* of divers bodies, under different circumſtances, are very numerous and conſiderable.

Mr. Hawkſbee gives us a number of experiments of this kind; particularly of the attrition, or *friction* of glaſs, under various circumſtances, the reſult of which was, that it yielded light, and became electrical.

All bodies by *friction* are brought to conceive heat; many of them to emit light; particularly a cat's back, ſugar, beaten ſulphur, mercury, ſea-water, gold, copper, &c. but above all, diamonds, which, when briſkly rubbed againſt glaſs, gold, or the like, yield a light equal to that of a live coal when blowed by the bellows. See ELECTRICS and ELECTRICITY.

FRICTION, in *Mechanics*, denotes the reſiſtance a moving body meets with from the ſurface on which it moves.

Friction ariſes from the roughneſs or aſperity of the ſurface of the body moved on, and that of the body moving: for ſuch ſurfaces conſiſting alternately of eminences and cavities, either the eminences of the one muſt be raiſed over thoſe of the other, or they muſt be both broke and worn off, but neither can happen without motion, nor can motion be produced without a force impreſſed. Hence, the force applied to move the body is either wholly, or partly, ſpent on this effect; and conſequently there ariſes a reſiſtance, or *friction*, which will be greater, *cæteris paribus*, as the eminences are the greater, and the ſubſtance the harder: and as the body, by continual *frictions*, becomes more and more poliſhed, the *friction* diminiſhes.

Hence it follows, that the ſurfaces of the parts of machines that touch each other ſhould be as ſmooth and poliſhed as poſſible. However it is found by experience, that the flat ſurfaces of metals, or other bodies, may be ſo far poliſhed as to increaſe *friction*; becauſe the attraction of COHESION becomes ſenſible, as we bring the ſurfaces of bodies nearer and nearer to contact. But as no body can be ſo much poliſhed, as quite to take away all inequality; witneſs thoſe numerous ridges diſcovered by the microſcope on the ſmootheſt ſurfaces; hence ariſes the neceſſity of anointing the parts that touch with oil, or ſome other fatty matter.

FRICTION, *laws of*. 1. As the weight of a body moving on another is increaſed, ſo is the *friction*.

This we ſee experimentally in a balance, which, when only charged with a ſmall weight, eaſily turns; but with a greater, a greater force is required.

Hence, if the line of direction of a moving body be oblique to the ſurface moved on, the *friction* is the greater; this having the ſame effect as an increaſe of weight.

And hence, again, as a perpendicular ſtroke or impreſſion is to an oblique one, as the whole ſine to the ſine of the angle of incidence; and the ſine of a greater angle is greater, and that of a leſſer leſs; the *friction* is the greater, as the line of direction approaches nearer to a perpendicular.

This is eaſily obſervable, and eſpecially in the teeth of wheels, which are frequently broke on this very account. The *friction*, therefore, is taken away, if the line of direction of the moving body be parallel to the ſurface.
